Prussiate of Soda—Higher prices have been established for this material on spot. Most sellers held 24c. per lb. as an inside figure. Demand is quite active, with spot goods limited in most quarters. Shipments were quoted around 23¾@23½c. per lb. c.i.f. New York.

Soda Ash—The general tone of this market is very strong, with bag material held at $1.75 per 100 lb. and barrels at $1.90. Smaller quantities command a small premium. Producers report an active call for contract requirements.

Coal-Tar Products

Restricted production combined with increased inquiries are chief factors in bringing about firm markets for several coal-tar products. Factors in benzol state that normal conditions are still somewhat remote, although a slight improvement in production was apparent. Spot goods are entirely nominal. The phenol market seems to be following the same strong course. No relief is in sight and while producers are not inclined to quote above 20c. per lb., they admit that future shipments are the only offerings. Spot supplies are entirely controlled by second hands and these interests are getting all they can for their holdings. Solvent naphtha has been noticeably diminished and the same condition is also true of cresylic acid. Benzoate of soda and benzoic acid are both maintained at sharp advances. Beta naphthol has been offered at 23c. per lb., with some odd lots still heard as low as 22c. The demand has improved slightly. Makers report lower prices at 20c. per lb. for aniline salts.

The St. Louis Market

ST. LOUIS, MO., Sept. 7, 1922.

This market has been very active for some time and in general displayed a very steady tone with some of the more important items notably strong. A rising tendency in prices was to be noted.

ALKALIS

The volume of *caustic soda* business has increased somewhat, but no change in price has as yet been reported. There are considerable stocks in the St. Louis market, for as yet the strike has caused no shortage. *Solid caustic* in 5- and 10-drum lots was quoted at $3.90 per 100 lb. delivered, with *flake* at $4.25. Very little carload business is being transacted. *Soda ash* is quoted at $2.20 in bags and $2.40 in barrels for 5- to 10-bbl. or bag quantities. *Bicarbonate of soda* has weakened slightly and is now quoted at $2.25 per 100 lb. in 1 to 5 bbl., a drop of 10c. per 100 lb. *Sal soda* is moving very slowly, but has not weakened in price; $1.65 per 100 lb. is being generally quoted on 1- to 5-bbl. lots with plenty of spot goods on hand.

GENERAL AND SPECIAL CHEMICALS

Producers in this section report a very extensive movement of *heavy mineral acids*, and prices are strong. *Carbolic acid crystals* have been moving very extensively during the past few weeks, and it is reported that the government surplus stocks are about depleted. The demand for *citric acid* is practically nil. *Oxalic acid* is still one of the prominent features of the market, with a very heavy demand and prices still on the upward flight. The demand for *ammonia water 26 deg.* has been very good and prices are firm. *White arsenic, powdered*, is reported strong with a heavy demand and supplies light, prices ruling at 8¼@9c. depending upon quantity and delivery. The *blue vitriol* market has quieted down considerably, with a freer movement. *Carbon bisulphide*, while still active, is not in as great a demand today as it was several weeks ago. *Copperas* is still on the scarcity list, and while prices remain unchanged at this time, an advance would not prove surprising. *Glycerine* has taken another advance and is now firm at 17c. in drums, with a further advance looked for. An 18c. glycerine market is to be expected before any further decline need be looked for. *Sulphur* is declining slightly and is quoted at $1.95 per 100 lb. in bags for the commercial grade. This is a decline of from 5 to 15c. per 100 lb. since our last report. *Zinc sulphate* is still very strong and going higher, with the market today at 3c. St. Louis, in carload lots; 3¼@3½c., St. Louis, in less carload lots.

VEGETABLE OILS AND NAVAL STORES

Castor oil remains firm at 14c. in drums, with quite a volume of business being transacted. *Turpentine* has advanced quite sharply and today's market is $1.26 per gal. in 5-bbl. lots or $1.32 in single barrels. *Linseed oil* is again moving in good sized quantities and is being quoted at 92c. in 5-bbl. lots, basis raw oil, and $1.02 in single barrels with the usual 2c. differential for boiled oil.

Nothing of note has happened in the market for other paint materials except that a duly expected rise in prices of *zinc oxide* has not arrived as yet, the market remaining as it was when last we reported.

The Iron and Steel Market

PITTSBURGH, Sept. 8, 1922.

The low point in production of pig iron and steel fell at the end of August, when the rate of pig-iron production was about 20,000,000 tons a year and steel mill operations were estimated at approximately 50 per cent of capacity, against a rate of close to 75 per cent late in June, when there was the heaviest operation since late in 1920.

Quite promptly upon the signing of the Cleveland agreement whereby mining of bituminous coal could be resumed under union auspices, production of pig iron and steel began to increase, the important channel to be opened involving coal to byproduct ovens and the coke to the adjoining blast furnaces. Up to date nearly if not quite a dozen blast furnaces, chiefly banked furnaces, have resumed, chiefly at Pittsburgh, in the Mahoning and Shenango valleys and in the Chicago district. With these furnaces operating in regular form, production of pig iron would be increased already by nearly 10 per cent, promising a corresponding increase in steel ingot production a very few days later.

It is a notable fact that there is not corresponding resumption of idle merchant furnaces. The merchant furnaces of the North depend chiefly upon Connellsville and West Virginia beehive coke, production of which has not materially increased, and upon surplus coke from the byproduct ovens of steel works when there is no surplus coke. The outlook for the merchant furnaces is distinctly unpromising at the moment.

NO SOFTENING IN STEEL MARKET

The increase that has occurred in operation of blast furnaces and steelmaking departments at steel plants is not a criterion that increases will continue indefinitely. Since the Cleveland agreement of Aug. 15 there has been rather rapid resumption of coal mining at union mines, but it is not certain that coal production will continue to increase to the limit of requirements. It is regarded as practically certain, indeed, that it will not, for railroad capacity will naturally, as usual, furnish the bottle neck.

In the retrospect, a notable feature of the situation at the moment is that there is no softening in the steel market position as a result of the ending of the coal strike. Such a softening was expected in most quarters. It is true the volume of steel buying has been relatively light in the past week, but this is not traceable plainly to indifference on the part of buyers. On the other hand it is clear that producers are reluctant to sell. Some are already sold far ahead, while those that are not have a feeling that they may be able to obtain better prices later. Presumably there are stocks of steel in the hands of some buyers, perhaps of many buyers, and it was thought in most quarters that the ending of the coal strike would be a signal to such buyers to liquidate. No such disposition is observable, thus far at least. The disposition of the average buyer, whether jobber or manufacturing consumer, is to build up stocks against the expected railroad congestion.

HIGHER PRICES FOR A NUMBER OF STEEL PRODUCTS

While no important steel price changes have occurred in the past week, the market has plainly stiffened in its general undertone. The minimum price on bars is 1.90c. and on plates and shapes 2c., these being understood to be the Carnegie Steel prices, although no official information is vouchsafed. The deliveries involved are indefinitely far ahead. The regular market, for reasonable deliveries, has been 2.25c. on all three of these products, and it is notable that some mills upon re-entering the market now are quoting this price as minimum. Plates for shipment in 2 or 3 weeks continue to bring 2.50c.

Sheets are selling at a variety of prices, depending on delivery time and the relation between mill and buyer. The leading interest is on the basis, as recently advanced, of 3.35c. for common black. Among independents there are various prices according to circumstances, 3.35c., 3.40c., 3.45c., 3.50c. and perhaps even 3.75c. Galvanized is quite uniformly 1c. above common black. Automobile sheets range from 4.70c. to 5c.

PIG IRON AND COKE

Pig iron continues to present practically a spot or prompt market. There is no selling beyond current stocks or production, as there is nothing definite as to when any merchant furnace will be able to resume. Foundry iron for Pittsburgh delivery continues to be controlled by Buffalo, the nearest point of supply, with a Buffalo price of $34, equivalent in the case of Pittsburgh delivery to an f.o.b. valley price of about $35.50. On small sales bessemer has brought $34 valley, a $2 advance in the week. Basic remains quotable at the conjectural figure of $30 valley, there being no bids or offers or any recent sales. It is related that $32 was quoted to one inquirer, who thereupon promptly withdrew the inquiry.

Connellsville coke is quotable at $11@$12 for furnace. While the furnace coke price would be quite objectionable to a furnace that has low-priced pig iron orders remaining to be filled, and would not be particularly attractive to a furnace with a clear order book, a fundamental objection to the situation is that there is not enough coke offered, all told, to enable a single furnace to build up an operation.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Lehigh Portland Cement Co., Allentown, Pa., has preliminary plans in progress for the construction of a new cement mill on a tract of land at East Birmingham, comprising about 250 acres, acquired a number of months ago. The plant will consist of a number of buildings to provide for a capacity of approximately 1,000,000 bbl. per annum, and is estimated to cost in excess of $600,000.

BIRMINGHAM—The McWane Cast Iron Pipe Co., Birmingham, has plans nearing completion for the construction of a new foundry at East Birmingham, on site recently acquired. The works will comprise a number of buildings, to be equipped for the production of about 8,000 ft. of small-sized pipe per day, and will give employment to about 150 men. It is expected to commence work within the next 30 days, and to have the plant ready for service early in the coming year. It will cost in excess of $85,000.

California

NATIONAL CITY—The Jet Oil Refining Co. has commenced the construction of a new refinery on local site, and plans to have the plant ready for machinery installation at an early date. It will be equipped for the production of lubricating oils.

ANAHEIM—The Anaheim Sugar Co. has awarded a general contract to G. E. Fickette, 638 South Western Ave., Los Angeles, for the construction of a new 5-story reinforced-concrete building at its plant, 45x260 ft., estimated to cost about $160,000.

ALHAMBA—The C. F. Braun Co., 604 Mission St., San Francisco, manufacturer of heating equipment, will commence the immediate construction of a 1-story foundry, at Shorb near Alhambra, in connection with a new works at this location, to cost about $65,000.

NATIONAL CITY—The California Gypsum Co. has plans nearing completion for the construction of a new plant on ocean front property, recently acquired, for the manufacture of gypsum blocks and other kindred products. It is estimated to cost in excess of $50,000.

Florida

BRADENTOWN—The Manatee County Fertilizer Co. has awarded a contract to J. C. Walden, Bradentown, for the construction of a new plant on local site. The main building will be 60x108 ft. The plant will have an initial output of approximately 100 tons of commercial fertilizer. J. H. Humphries is president.

Georgia

ROME—The B. Mifflin Hood Brick Co., Atlanta, has plans in progress for extensions and improvements in the plant of the Rome Fireproofing Co., recently acquired. The work will cost about $75,000, including new equipment. The company has also purchased a large tract of clay deposits in the vicinity of the Rome plant, and proposes extensive development.

CAIRO—The Farmers' Co-operative Cane Syrup Association is having plans prepared for the construction of a local plant with initial daily capacity of about 10,000 bbl.; an extensive storage works will also be built.

CAMILLA—The J. P. McRee Turpentine Co., recently organized with a capital of $75,000, has preliminary plans under consideration for the establishment of a local plant for the manufacture of turpentine, rosin and kindred products. J. P. McRee heads the company.

Idaho

MACKAY—The Republic Consolidated Mining & Refining Co., recently organized with a capital of $3,000,000, has plans in progress for the construction of a new concentrating mill and cyanide plant at its properties in this section. A hydro-electric power plant will also be constructed. W. P. Barton is in charge. The project will cost about $150,000.

Illinois

CHICAGO—The National Paint & Wall Paper Co., care of Clarence Hatzfield, 7 South Dearborn St., architect, is completing plans for the construction of a new 1-story and basement plant, 50x105 ft., at 4317 Grand Ave. Bids will be asked at once.

PULLMAN—The Pullman Foundry Co. will soon commence the construction of a new 1-story foundry, 300x500 ft., to cost about $40,000, exclusive of equipment. Plans have been completed by Frank D. Chase, 645 North Michigan Ave., Chicago, architect and engineer.

Indiana

SPEED—The Louisville Cement Co., Louisville, Ky., has work under way on the rebuilding of its local cement-manufacturing plant, destroyed by fire early in July. It is proposed to increase the capacity at the new plant from 1,800 bbl. per day, the output of the former mill, to 2,500 bbl. per day. All equipment will be electrically operated. The new mill will cost close to $300,000, and is expected to be ready for service at an early date.

Louisiana

KENTWOOD—The Chamber of Commerce is perfecting plans for the establishment of a local mill for the manufacture of paper and pulp products. It is purposed to organize a company to operate the plant. H. A. Addison, secretary, is in charge.

BOSSIER CITY—The Louisiana Oil Refining Corp., Shreveport, is arranging for the early operation of its new plant here, now nearing completion, for the production of grease and lubricating oils. The works will have an initial capacity of about 9,000 lb. of grease and 250 bbl. of lubricating oil per day. It is proposed at a later date to extend the works, which now represents an investment of about $30,000.

Maryland

BALTIMORE—The city water department will commence preliminary work at once for an addition to the municipal water-filtration plant at Montebello, estimated to cost about $1,500,000. It is planned to award contracts for different features of the project, including machinery, by the close of the year.

Massachusetts

WATERTOWN—The Hodd Rubber Co., Nichols Ave., has awarded a general contract to William H. Illiffo, Bailey Rd., for the construction of a 2-story addition to its plant, 96x200 ft., to cost about $75,000.

WORCESTER—The Norton Co., manufacturer of abrasive products, will commence the immediate construction of a new 4-story building at its plant, 50x125 ft. Steel storage tanks and other operating equipment will be installed.

HAVERHILL—Fire, Aug. 19, destroyed one of the buildings at the plant of the Haverhill Box Board Co., manufacturer of paper products, with loss approximating $100,000.

CAMBRIDGE—The Cambridge Rubber Co., 748 Main St., will commence the immediate construction of a new 4-story plant, 83x104 ft. A general contract for the work has been let to the Scully Co., Cambridge.

Michigan

BAY CITY — The Laetz Foundry Co. is planning for the early occupancy of its new local plant, now nearing completion. It will be used for the production of a general line of metal castings.

MONROE—The new plant of the Republic Glass Co., now in course of construction, will be equipped to give employment to about 150 persons, and this working force will be increased at a later date. It is expected to have the works ready for service late in October. The company has established general offices at 207 South Macomb St. Manuel Llera is president; and J. H. Williams, secretary and treasurer.

Missouri

COLUMBIA—The City Council is arranging for the purchase of the artificial gas plant of the Columbia Gas Co., to be operated in the future as municipal property. It is planned to make extensions and improvements. Bonds for $100,000 are being arranged.

Montana

GREAT FALLS—The Silver Dyke Mining Co., operating at Hiehart, near Great Falls, is planning for the erection of a new concentrating plant, with daily capacity of about 250 tons.

New Jersey

NEWARK—The Alcohol Products Co. Blanchard St. and the Passaic River, has awarded a contract to Fred Kilgus, Inc., 13 South 6th St., for the erection of a 1-story plant addition, 40x145 ft. Work will be commenced at once.

OLD BRIDGE — The local plant of the Brookfield Glass Co., has been acquired by new interests, represented by William J. Burke, 99 Nassau St., New York, attorney, which plan to operate the works. The new owners are said to be organizing a company to manufacture a line of glass specialties, and will take immediate possession of the property.

CEDAR GROVE—The Department of Streets and Public Improvements, City Hall, Newark, is planning for the construction of a 1-story chemical laboratory, 26x48 ft., to cost about $20,000, for testing work in connection with the city waterworks at Cedar Grove. The Bureau of Water, John A. Foulks, engineer, is in charge.

New York

LONG ISLAND CITY—The A. C. Horn Co., Bodine and Hancock Sts., manufacturer of waterproofing products, will commence the immediate erection of a 3-story addition to its plant. Plans have been prepared by William Schoen, 507 5th Ave., New York. A. C. Horn is president.

ROCHESTER—Fire, Aug. 22, destroyed a portion of the tankage department of the Monroe County Oil Co., with loss estimated at about $15,000. It will be rebuilt.

ELMIRA—The Elmira Water, Light & Railroad Co., Heulett Bldg., will commence the immediate erection of a new artificial gas-manufacturing plant, estimated to cost about $300,000, including equipment. It will be located at Madison Ave. and East 5th St.

BROOKLYN—The Aetna Varnish Co., Maspeth and Vandervoort Aves., has plans under way for the erection of a new 1-story plant 80x100 ft., to cost about $20,000. Louis Allmendinger, 20 Palmetto St., is architect.

SPARKILL—The Standard Oil Co., 26 Broadway, New York, has preliminary plans under consideration for the erection of a new oil refinery on local tract of property recently acquired, comprising about 1,500 acres of land. The new works will consist of a number of buildings and is said to be estimated to cost in excess of $500,000.

YONKERS—The Kober Chemical Co., 24 Grey Oakes Ave., is completing plans and will soon call for bids for the erection of a 2-story chemical laboratory, 40x70 ft., on Grey Oakes Ave., estimated to cost about $42,000.

Ohio

EAST AKRON—The Trump Rubber Co., operating at the former local plant of the Denmead Rubber Co., manufacturer of mechanical rubber products, has plans nearing completion for the erection of a new local plant for the manufacture of automobile tires, to be equipped for an initial output of about 100 tires per day.

NILES—The Electric Alloy Steel Co., Youngstown, O., is perfecting plans for the erection of a new plant at Niles, to comprise open-hearth alloy steel furnaces, rolling mills, etc., for the production of high-speed steel products.

Oklahoma

OKLAHOMA CITY—The Kenyon Brick & Tile Co., 2700 West 10th St., is planning for the installation of new equipment at its plant, including mixing machinery, press, etc. A. W. Kenyon is president.

PONCA CITY — Miller Brothers, operating the 101 Ranch, will commence the immedi-

e rebuilding of the tanning plant on their operty, recently destroyed by fire. It will ve a capacity of 200 hides per day, and th power plant and other works buildings, ill cost about $100,000.

ARDMORE—The Indiahoma Refining Co. ederal Reserve Bank Bldg., St. Louis, Mo., negotiating for the purchase of the local l refinery of the Chickasaw Refining Co., hich has been inactive for about a year ast. Upon acquisition, it is purposed to ake extensions and improvements, includ- g machinery repairs, and place the plant service at the earliest possible date. E. . Schock is head of the Indiahoma com- any.

Pennsylvania

JEANETTE—The American Window Glass o., Farmers' Bank Bldg., Pittsburgh, will ake bids at once for the erection of an ddition to its local glass plant, to duplicate, pproximately, the present 12-tank building t the works. The installation will com- rise twelve cylinder blowing machines, anks, glass conveyors and other machinery. n appropriation of about $1,500,000 has een made for the expansion. Willian L. lonro is president and general manager.

WHITE HAVEN—The Peerless Explosive o. will make extensions and improvements n the plant of the Miller Powder Works, ce Lake, near White Haven, recently ac- uired, and plans to commence operations at n early date. Employment will be given o about 100 men.

ALLENTOWN—The Ford-Rennie Leather o., recently organized under Delaware laws as leased the former plant of the Victor eather Co., Auburn St., near the East Penn unction, and will operate a tannery for the manufacture of glazed kid products. John D. G. Rennie is president; and James I. Ford, treasurer.

PHILADELPHIA — The M. L. Shoemaker Fertilizer Co., Venango St. and the Dela- ware River, is planning for the rebuilding of the portion of its plant, recently destroyed by fire, with loss reported in excess of $400,000, including buildings and equipment.

South Carolina

LAURENS—The Laurens Glass Works, Inc., has plans in progress for the rebuilding of the portion of the main building at its plant, recently destroyed by fire. Albert Dial is president.

Tennessee

KNOXVILLE—The Knoxville Porcelain Co., recently organized with a capital of $370,000, has acquired property at Lonsdale, near Knoxville, comprising about 5 acres of land, as a site for the erection of a new plant for the manufacture of porcelain products for electrical service. The initial works will consist of a 3-unit plant, estimated to cost about $100,000. J. N. Houser is pres- ident, and O. C. Duryea, vice-president.

MEMPHIS—The Commercial Chemical Co., 394 South Front St., is reported to be plan- ning for the rebuilding for the portion of its works, destroyed by fire, Aug. 19, with loss approximating $40,000.

Texas

BEAUMONT—The White Eagle Oil & Refin- ing Co., Kansas City, Mo., has tentative plans under consideration for the construc- tion of a new oil storage and terminal plant here to cost about $250,000, including equipment, for export service. It is expected to commence work at an early date.

West Virginia

WIERTON—The Wierton Steel Co. will soon commence the installation of a new byprod- ucts coke plant, to comprise a battery of 37 ovens and auxiliary equipment, with capacity of about 600 tons of coke per day.

Industrial Developments

LEATHER — The Charles S. Walton Co., Philadelphia, Pa., is increasing production at its tanneries. The currying plant has been placed on a full capacity basis.

The Griess-Pfleger Tanning Co., Cincin- nati, O., is running full in its different plant departments, giving employment to a reg- ular working force. A new hide and skin storage plant has been completed and will be placed in service at once.

CERAMIC — All refractory plants in the vicinity of Mount Union, Pa., are operating at capacity, giving employment to normal working forces, including the Harbison- Walker Refractories Co., the General Re- fractories Co. and the United States Refrac- tories Co. Wages have been advanced at the plants for all classes of employees, averaging from 60 to 80 cents a day; the schedule for laborers has been increased from $2.70 to $3.50 per day.

The Vitrified Brick & Tile Co., Collins- ville, Okla., has adopted a night shift at its plant, in addition to a regular day force, and will operate on a basis of 5 carloads of material per day for an indefinite period. The company is said to have orders on hand for over 200 carloads of vitrified brick.

Owing to fuel shortage, a number of brick-manufacturing plants in the Akron, O., district have been forced to shut down or curtail production. Two plants are still running full. Operations will be resumed as soon as the situation improves.

Potteries at Trenton, N. J., are arranging for a full resumption of production as soon as a supply of anthracite coal is available. Fuel shortage has caused a number of the plants to curtail operations during the past few weeks. The present local supply of anthracite for this branch of industrial work is low.

A number of brick plants in Nansemond County, Va., and other parts of the state are refusing orders, owing to inability to make shipments and deliveries on account of the rail strike. The Virginia-Carolina Brick Manufacturers' Association has ap- plied to the state fuel distributor, Rich- mond, to grant priority shipments to the industry.

IRON AND STEEL—The Trumbull Steel Co., Youngstown, O., has resumed operations at its plant at Warren at close to normal capacity, on a basis of about 40,000 tons per month.

The American Sheet & Tin Plate Co., Elwood, Ind., is maintaining active produc- tion at its local mills, giving employment to more than 500 men.

The Monterey Iron & Steel Co., Monterey, Mexico, is increasing production at its mills, and is now operating at practically full capacity. The steel output has been ad- vanced from 400 to 500 tons per day, and will be further increased to a maximum of 600 tons at an early date. With three open-hearth furnaces in service, arrange- ments are being made to place the fourth unit at the plant in operation, at which time the working force will be increased by about 1,500 men. A recent increase in employees has been made from 2,000 to 3,500.

The Iron Products Corp., Bessemer and Anniston, Ala., has adopted a capacity basis of operation at all of its local plants, includ- ing coke works.

The Crucible Steel Co. of America is maintaining production at its Syracuse, N. Y., plant at close to normal, with employ- ment of regular working force.

The Midvale Steel & Ordnance Co., Phila- delphia, Pa., has adopted a present basis of operation of about 50 per cent of normal at its plants.

The American Sheet & Tin Plate Co. is increasing operations at its Shenango works, near New Castle, Pa., and has recently added about 100 ment to the working force.

Owing to coke and coal shortage, blast- furnace operation in the Buffalo, N. Y., has been curtailed to 5 active stacks out of a total force of about 25,000 men.

METALS—The American Smelting & Refin- ing Co. is planning for the resumption of operations at its plant at Monterey, Mexico, which has been idle for a number of years past. The company is operating its smelt- ing and refining plant at Tacoma at full capacity, giving employment to the regular working force.

The Utah Zinc Co., Salt Lake City, Utah, is running under heavy output at its local plant. The mill has orders on hand for some time to come for zinc oxide for the rubber and paint industries.

MISCELLANEOUS—The Darco Corp., Mar- shall, Tex., is running at full capacity at its local plant unit, recently completed, for the production of Darco, or coloring material for food products, and other service. The first full-car shipment has left the plant, and others will follow on a regular working schedule. Additional plant units will be constructed in the future.

The American Window Glass Co. is oper- ating with a working force of more than 700 men at its plant at Jeannette, Pa., at close to normal output. A wage increase of from 15 to 22 per cent has been made.

The Lehigh Portland Cement Co., New Castle, Pa., has resumed operations at its local mills, following a recent curtailment due to a strike of operatives. The men have been granted a 20 per cent wage advance. About 700 employees are affected.

The International Cement Co., New York, has been forced to curtail operations at its Knickerbocker cement plant, owing to the coal and rail strike. It is expected to re- sume as soon as the situation improves.

The Solvay Process Co., Solvay, near Syracuse, N. Y., is maintaining operations at its local plant at close to normal, with employment of regular working force.

Glass plants at Millville, N. J., are ar- ranging for an immediate resumption of operations, following the regular seasonal shut down in July and August. A large force of men is busy in placing the plants in readiness for full blast. A number of plants have accumulated orders to insure capacity production for some time.

The Smithville Oil Mill Co., Smithville, Tex., has resumed operations at its local cottonseed oil mill, closed for a number of months past. Production will be in- creased gradually until a day and night force is engaged. It is expected to keep the plant running full well into the winter.

The J. R. H. Products Co., Willoughby, O., specializing in the production of barium dioxide, has closed its plant for an indefinite period, owing, it is said, to foreign competi- tion. The plant has been giving employ- ment to close to 100 men.

The McMurray Asphaltum & Oil Co., Waterways, near Edmonton, Alta., is ar- ranging for immediate increased operations for the production of lubricating oils from tar sands. Machinery will be installed for this purpose.

New Companies

THE THOMAS ENGINEERING LABORATORIES, INC., Newark, N. J., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture paints, varnishes, etc. The incorporators are John H. Thomas, Milton A. Smith and Edward T. Moore.

THE BREWER MFG. CO., Grand Rapids, Mich., has been incorporated with a capital of $200,000, to manufacture spark plug por- celain products and kindred specialties. The incorporators are Ray E., John A. and C. G. Brewer, 1103 Front Ave., N. W., Grand Rapids.

THE HENDERSON OIL & REFINING CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representa- tive, has been incorporated under state laws with a capital of $1,000,000, to manufacture petroleum products.

THE NATIONAL PAINT WORKS, INC., Bos- ton, Mass., has been incorporated with a capital of $50,000, to manufacture paints, varnishes, etc. Philip Shurdut is president; and Frank V. Jordan, 237 Redlands Road, West Roxbury, Mass., treasurer.

J. C. SEITZ & CO., INC., Buffalo, N. Y., care of Dirnberger & Moore, attorneys, Buf- falo, representative, has been incorporated with a capital of $200,000, to manufacture tires, tubes and other rubber products. The incorporators are J. C. and E. W. Seitz, and H. F. Robinson.

A. BELL & SON, INC., Providence, R. I., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are Hiram G. Hall, Clive D. Waite and John M. Clifford, all of Providence.

THE SULFEX CO., Newark, N. J., has been incorporated with a capital of $10,000, to manufacture chemicals and chemical by- products. The incorporators are Louis C. Owens, Jr., Charles P. Stewart and Ber- tram W. Saunders, 264 Jelliff Ave., Newark.

THE MACINNES MFG. CO., 10925 South Michigan Ave., Chicago, Ill., has been in- corporated with a capital of $24,000, to manufacture paper, fiber and kindred prod- ucts. The incorporators are Neil and M. V. MacInnes, and Harold L. Hart.

H. A. DEFRIES, INC., New York, care of N. F. Schmidt, 220 Broadway, representa- tive, has been incorporated with a capital of $20,000, to conduct metallurgical opera- tions. The incorporators are R. Chaplin, E. Goldberg and J. V. Ecker.

THE ACME PRODUCTION CO., New York, care of the Registrar & Transfer Co., 900 Market St., Wilmington, Del., representa- tive, has been incorporated under Delaware laws with capital of $2,500,000, to manu- facture petroleum products.

THE CHLORIDINE CO., Memphis, Tenn., has been incorporated with a capital of $10,000, to manufacture chemical products. The in- corporators are H. R. Bynum, P. C. Schalz and A. C. Grube, all of Memphis.

THE NEW PROCESSES CO., Indianapolis, Ind., has been incorporated with a capital

of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are George P. Shippey and Raymond L. Walker, both of Indianapolis.

MORRIS B. READE, INC., Nutley, N. J., has been incorporated with a capital of $5,000, to manufacture chemicals and chemical byproducts. The incorporators are Jacob Muller and Morris B. Reade, 72 High St., Nutley.

THE PROCESS CHEMICALS, INC., New York, care of M. P. Schaffer, 1463 Broadway, representative, has been incorporated with a capital of $1,250,000, to manufacture chemicals and chemical byproducts. The incorporators are A. P. Burch, E. Stempel and A. E. Wolz.

THE COLUTH CHEMICAL CO., Indianapolis, Ind., has been chartered under state laws to manufacture chemical specialties. The incorporators are Howard C. Baker, William M. Love and Thomas M. O'Connor, all of Indianapolis.

THE METAL PENETRATING COLOR CORP., New Haven, Conn., has been incorporated with a capital of $25,000, to manufacture a special metal process known as penetrating color. The incorporators are George R. Doolittle and William H. Unmack, 152 Whalley Ave., New Haven.

THE CLARK CHEMICAL CO., INC., Boston, Mass., has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. Nelson B. Clark, 166 Lawrence St., Malden, Mass., is president and treasurer.

THE NORTH AMERICAN OIL & MFG. CO., 2319 North Seeley Ave., Chicago, Ill., has been organized to manufacture refined oil products. The company is headed by C. J. Christie and E. A. Schillinger.

THE DAVID HASSETT CORP., New York, N. Y., care of Burnett, Sorg, Murray & Duncan, 810 Broad St., Newark, N. J., representatives, has been incorporated with a capital of $100,000, to manufacture fiber products. The incorporators are D. H. Hassett, G. B. Bailey and F. E. Stults.

THE WAXENE MFG. CORP., Bloomington, Ind., has been incorporated with a capital of $60,000, to manufacture waxes, polishes, varnishes, etc. The incorporators are Halbert M. Wood, Oscar H. Cravens and J. E. P. Holland, all of Bloomington.

THE CHICKASAW REFINING CORP., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., has been incorporated under state laws with a capital of $10,000,000, to manufacture refined petroleum products.

THE MERCHANTVILLE ALUMINUM & BRASS WORKS, INC., Merchantville, N. J., has been incorporated with a capital of $100,000, to manufacture aluminum, brass and other metal products. The incorporators are Peter Bernacki, Andrew Raroha and Dean S. Renwick, 511 Market St., Camden, N. J. The last noted represents the company.

THE KRISGOLD LEATHER CO., Chelsea, Mass., has been incorporated with a capital of $10,000, to manufacture leather products. George L. Goldman is president; and Jacob Kristal, 29 Franklin Ave., Chelsea, treasurer.

THE GULF STATES CHEMICAL & REFINING CO., Birmingham, Ala., has been organized to manufacture chemicals and chemical byproducts, and affiliated specialties. J. A. Moore, Jr., is president; and J. M. Gilby, Jr., vice-president, both of Birmingham.

L. HANERFELD, INC., New York, N. Y., care of Holley & Oxenberg, 50 East 42nd St., New York, representatives, has been incorporated with a capital of $15,000, to manufacture glass products. The incorporators are L. Hanerfeld, B. Finkelstein, and J. A. Sheridan.

THE ALLYNDALE LIME CO., Hartford, Conn., has been incorporated with a capital of $50,000, to manufacture lime and kindred products. The incorporators are Samuel Gilbert, Benjamin Gaberman, both of Hartford; and M. S. Tracy, Glastonbury, Conn.

THE UNIVERSAL SODA & POTASH MINES, INC., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under state laws, with capital of $60,000, to manufacture soda, potash and kindred products.

THE OGDEN PRODUCTS CO., 3258 Ogden Ave., Chicago, Ill., has been incorporated with a nominal capital of $5,000, to manufacture chemicals and affiliated products. The incorporators are Charles Martin Sals, William Greenberg and Daniel D. Lichtenstein.

THE MORGANTOWN MANTEL & TILE CO., Morgantown, W. Va., has been incorporated with a nominal capital of $5,000, to manufacture tile and other ceramic products. The incorporators are H. L. Winter, James Fancey and O. M. Herod, all of Morgantown.

THE BOLTA CO. OF AMERICA, care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $1,000,000, to manufacture chemicals and chemical byproducts.

THE MARYLAND-VIRGINIA OIL CORP., 1010 Keyser Bldg., Baltimore, Md., has been incorporated with a capital of $500,000, to manufacture petroleum products. The incorporators are E. E. Hoch and L. R. Athey.

THE FRENCH MFG. CO., Seymour, Conn., has been incorporated with a capital of $50,000, to manufacture rubber specialties and affiliated products. The incorporators are C. M. and E. D. French, and C. J. Atwater, all of Seymour.

THE AETNA ALUMINUM & BRASS CASTINGS CO., 834-36 West 49th Place, Chicago, Ill., has been incorporated with a capital of $6,000, to manufacture aluminum, brass, bronze and other metal castings. The incorporators are F. A. B. Smith, William F. Bodong and Joseph A. Koehler.

THE TREMONT OIL CO., Chicago, Ill., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $500,000, to manufacture petroleum products. The incorporators are R. W. Taylor, J. N. Fulton and T. Goodrich.

THE CROTON CHEMICAL CORP., New York, N. Y., care of N. L. North, Jr., 32 Court St., Brooklyn, N. Y., representative, has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are H. H. Walker and N. P. Hicks, Jr.

THE BURKHART-SCHAIR CHEMICAL CO., Chattanooga, Tenn., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. A. C. Brukhart, Chattanooga, is president.

THE IDEAL MFG. CO., care of the Delaware Charter Co., 904 Market St., Wilmington, Del., has been incorporated under state laws with a capital of $80,000, to manufacture iron, brass, bronze and other metal castings.

THE MARION PRODUCTION CO., Marion, Ind., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Omar F. Brown, Edgar S. Lane and Charles W. Beach, all of Marion.

THE OLD COLONY-RYNAK LEATHER CO., Boston, Mass., has been incorporated with a capital of $100,000, to manufacture leather products. Walter Reinstein is president; and Henry Yozell, 40 County Road, Chelsea, Mass., treasurer.

Capital Increases, Etc.

THE COMMERCIAL CHEMICAL CO. OF TENNESSEE, Memphis, has filed notice of increase in capital from $2,500,000 to $2,750,000.

THE NEWPORT CO., Carrollville, Wis., manufacturer of heavy industrial and other chemicals, has disposed of a bond issue of $3,000,000, for general expansion, operations, etc. J. W. Shaeffer is president.

THE GLEN FALLS PORTLAND CEMENT CO., Glen Falls, N. Y., has filed notice of increase in capital from $600,000 to $1,200,000, for general expansion.

A petition in bankruptcy has been filed against the BROWN LEATHER CO., 1153 West Roosevelt Rd., Chicago, Ill. The liabilities are said to total $35,000, with assets close to a like amount.

THE UNITED STATES RUBBER CO., Akron, O., has arranged for a bond issue of $7,000,000, the proceeds to be used for general financing, expansions, etc. C. B. Seger is chairman of the board.

THE CENTURY CUT GLASS CO., Saugerties, N. Y., has filed notice of dissolution under state laws.

THE CLINTON TIRE & RUBBER CO., Toledo, O., has filed notice of change of name to the Wildman Tire & Rubber Co., at the same time increasing its capital from $100,000 to $2,200,000, for proposed expansion.

THE CUBA CANE SUGAR CORP., 112 Wall St., New York, operating sugar refineries in Cuba, has approved a bond issue of $10,000,000, to be used for general financing in connection with its subsidiary, the Eastern Sugar Corp.

THE NEW YORK VITREOUS ENAMEL PRODUCTS CORP., a Delaware corporation, has filed notice of organization to operate in New York for the manufacture enamelware products, with capital of $100,000. J. R. Greenwood, 66 Myrtle Ave., Brooklyn, represents the company.

Industrial Notes

THE CONVEYORS CORPORATION OF AMERICA, Chicago, Ill., announces that the Florandin Equipment Co. has been organized by C. H. Florandin, with offices at 110 West 40th St., to act as its New York representative. The new organization will also do a general contracting business in and around boiler rooms and industrial plants located in New York City and its vicinity, erecting and installing the lines of equipment which the organization handles. The Conveyors Corporation of America has also appointed the Mid-West Engineering Sales Co., Masonic Temple, Cedar Rapids, Iowa, representative in eastern Iowa, for the sale of the American trolley carriers, which are coal-handling equipment of the monorail type. J. W. Holden, who is manager of the Mid-West Engineering Sales Co., is well known in Cedar Rapids and vicinity.

THE MORSE CHAIN CO., Ithaca, N. Y., announces that due to increasing business it was necessary to move the Philadelphia office to larger quarters. It is now located at 612 Franklin Trust Bldg., 18-22 South 15th St. J. A. Meaney is district manager for that office.

W. A. JONES FOUNDRY & MACHINE CO., Chicago, Ill., announces the opening of another branch sales and engineering office at 2482 University Ave., St. Paul, Minn. C. F. Ford, who is in charge of this new branch, is an experienced transmission engineer and qualified to assist in elevating, conveying and power transmitting problems.

CELITE PRODUCTS, LTD., has been established in Canada to market Sil-O-Cel and Filter-Cel, as produced by the Celite Co. in the United States. Stock of these materials will be maintained in the New Kirks Bldg., Montreal. Lawrence Russel has been appointed manager.

THE J. R. ALSING ENGINEERING CO., 50 Church St., New York City, established in 1869 to develop pebble mills in this country under patents issued to J. R. Alsing in the early '70s, has recently undergone a reorganization. It has been taken over by W. W. Searle and Edward W. Lawler, the latter acting as general manager of the company. Mr. Lawler was previously manager of the Hardinge Co. of New York, which position he left 2 years ago.

THE BUCKEYE DRYER CO. has removed its main office from 243 North High St., Columbus, O., to 29 South LaSalle St., Chicago, Ill.

LESLIE H. WEBB, vice-president of the Wedge Mechanical Furnace Co. of Philadelphia, has recently assumed the management of the Pittsburgh offices of the Pennsylvania Salt Mfg. Co., the parent company of the Wedge Mechanical Furnace Co.

Coming Meetings and Events

ALPHA CHI SIGMA dinner, during the Chemical Exposition, will be held Thursday, Sept. 14, at 6:30 p.m. at Keen's Chop House, 107 West 44th St., New York City. Members are requested to register at *Chem. & Met.'s* booth at the Exposition.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its 126th meeting at San Francisco, Calif., Sept. 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS is holding its sixteenth annual convention Sept. 11 to 15 at Cleveland Public Hall, Cleveland, Ohio.

NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (EIGHTH) is being held in New York, Sept. 11-16.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer, but will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

Looking a Gift Horse in the Mouth

OF THE important announcements made at the Pittsburgh meeting of the American Chemical Society none received more popular approval or wider publicity than that of the gift of an annual prize of $25,000 by the Allied Chemical & Dye Corporation. It is to be awarded to that American chemist who, in the opinion of a proper committee, has done most for the advancement of chemistry. The applause that greeted the announcement in Council meeting found an echo in the daily press throughout the length and breadth of the land. But during the remainder of the week the prize was a topic of frank discussion that belied the sincerity of the enthusiasm with which its announcement apparently was received. The general tenor of the conversation was, "The prize is a great thing for American chemistry, but——."

It is proverbially bad taste to look a gift horse in the mouth, but in this particular instance we think that comment is fairly invited. The organization of the Allied Chemical & Dye Corporation was a fine industrial conception. But events would seem to indicate that under the leadership and control of EUGENE MEYER, ORLANDO WEBER and their fellow syndicate members there has been a more abiding interest in finance than in chemical industry. The lack of chemical understanding and chemical sympathy at the top have found expression in the wrecking of research organizations and the emasculation of companies as far as chemists are concerned. Wholesale reorganization involving the discharge of employees from office boys to presidents has extended even to the removal from the list of aged pensioners who have given their lives to their employers. The policy pursued has, moreover, disturbed the morale of the remaining technical employees to a point where they have neither respect for their employers nor pride in their jobs. That they continue to do their work to the best of their ability is only a matter of self-respect.

It is conceivable that after pursuing this policy to a point where it has alienated the interest and friendship of the chemist, the corporation should now seek to gain his favor. But it will require atonement in other ways than by the gift of a cash prize to wipe out this blot on the 'scutcheon of American chemical industry. Of course the offer will be accepted and the prize awarded through the medium of the American Chemical Society, and undoubtedly the money will be joyfully accepted by the fortunate recipient, despite the fact that some have said they would scorn it, while others would devote it to the support of cast-off pensioners. The prize is a fine gesture, but it is not a convincing argument that the financial leadership of American chemical industry has been converted.

The Coal Industry On the Carpet

"I DO NOT believe great solutions are to be found out of emotional denunciations, but out of sober scientific examination," said HERBERT HOOVER to the chemical salesmen last week in discussing the coal industry in the United States. In his opinion, a sober, scientific examination of the coal industry by a national coal commission fully empowered to get at the bottom of the trouble is the plan that offers the greatest opportunity for constructive work since the war. Three times in recent years the coal industry has reduced the country to a point of industrial collapse because of a shortage of elementary and vital raw material. When an industry cannot so regulate itself as to avoid such impasses it is time for the public to step in and protect its interests through Congressional legislation.

The trouble with the coal industry is patent. It has a capacity of about 800,000,000 tons per year, whereas the maximum consumption is only 500,000,000 tons. Even in years of boom there are 200,000 surplus miners in the industry, and the average employment time is roughly 60 per cent, not counting strikes. Thus the public has to pay for 40 per cent idleness. The nation is forced to permit miners to live according to a standard out of proportion to their services, and that on only 60 per cent of productive work. In other words, the problem of the coal commission will be to develop some method whereby properties can be liquidated and miners turned into other industries, in order that the cost of the commodity may not be exorbitant. The overhead of the industry must be cut down. All this must be accomplished with an adjustment that shall be fair to employer and employee, but it should not be an impossible task.

Pittsburgh Entertains American Chemical Society

JUST as Milwaukee undoubtedly has claims to fame that were not wiped out by the adoption of the Eighteenth Amendment, so Pittsburgh would be perpetuated in the minds of chemists even if the reformer succeeded in placing a ban on the familiar stogey. Certainly the 1,300 chemists who registered at the Pittsburgh meeting of the American Chemical Society would be the last to forget the scientific excellence as well as the lively hospitality of the Pittsburgh Section.

One finds a peculiar spirit of co-operation and emulation among these chemists of the Smoky City. Due to the large number of industries centering in Pittsburgh there are groups of chemists, each of which is at once a competitive but co-operative unit in advancing the chemical industry. We are told that this spirit not only finds its expression in the annual outing and field day of the section, but that it is also a large factor in de-

veloping that quality of humanity that takes the curse off the cold scientific character of the profession.

Those who were responsible for the program of the Pittsburgh meeting showed rare judgment in one or two respects. In the first place, the formal dinner was abandoned for the more delightful sociability of a garden party and outdoor theatrical performance. Second, the smoker was enlivened by the fact that the various numbers on the program were performed by members of the local section. Evidently when it comes to making fun, the Pittsburgh Section "rolls its own." Without showing partiality, we think the skit prepared by the chemists of the Aluminum Co. of America deserves special mention, and we hope to publish it later as a contribution to the lighter vein in which chemists sometimes indulge.

The general and technical sessions had the customary interest for those in attendance. As usual the programs were entirely too long and many of the 457 papers were unworthy of a place in the list. Among the divisions and sections reporting good programs and good attendance were those devoted to rubber, cellulose, leather, petroleum, and industrial and engineering chemistry. For some reason or other the division of fertilizer chemistry was poorly attended—a delinquency that should be remedied if the division is to satisfy what is admittedly a large field of industrial chemistry. Perhaps less attention to methods of analysis and more to the broad problems of the industry will develop a strong division.

On the whole, the Pittsburgh meeting was one of the best that has been held and the Pittsburgh Section is entitled to the thanks of the visitors for the excellence of the arrangements.

Two Shifts and Three Shifts in Steel

A LARGE amount of information and opinion is accumulating on the question of the iron and steel industry eliminating the two-shift system of operation, where employed, in favor of a universal three-shift system. To the various studies made in past years there have now been added two long reports presented respectively by BRADLEY STOUGHTON and HORACE B. DRURY at a meeting September 8 of the executive board of the American Engineering Council of the Federated American Engineering Societies. Further, pursuant to the recent suggestion of President HARDING, a committee of the American Iron and Steel Institute is also at work on the subject.

The investigators find it necessary to consider the matter from many viewpoints. Even the barest outline of the subject cannot be given in this column. The momentary mental attitude of labor is a matter of importance. There is the question how many of the foreign born might become restless with an 8-hour day and seek 12-hour employment. Then there is the question of attracting classes of men who do not now gravitate toward blast furnace or steel mill employment. A point brought out in one of the reports now available is that with the introduction of more machinery the peak loads of activity, involving necessary rest periods, are reduced.

The literature thus far has been prepared chiefly by engineers and men who may in a sense be called social workers. The views of strictly business men will no doubt be incorporated in the report to be made by the American Iron and Steel Institute. From the business viewpoint, there seems to be good reason for making an effort to change from the two-shift to a three-shift system as soon as possible. Obviously the change must be made some time. Costs, wage rates and selling prices are in a particularly unstable condition now, hence less disturbance is promised than might prove to be the case later. Wage rates were declining sharply in 1921, while on the first of this month a 20 per cent advance went into effect in the industry. The price of one finished steel product or another sometimes changes several dollars a ton almost over night. There was much unemployment last year, while of late there has been a decided labor shortage at many plants. Nothing being at all fixed, changes can now be made better than at other times.

One suggestion has been made that deserves particularly careful consideration. It is that the man might be given the same hourly rate as formerly, whereby he would receive two-thirds as much per day, but with a bonus attached according to performance of the unit at which he is employed, whereby his weekly earnings might prove as large as formerly if not larger. This is a very attractive subject. A veteran in the iron and steel industry who recently retired from an important position after many years of service, a man noted for initiative, has often expressed the opinion that "payment by results" could be made to work in the iron and steel industry. He has insisted that some plan could be devised that would eventually prove practicable. Here is an opportunity to try the principle. Two changes would disturb conditions no more than one, so that there would be a chance to kill two birds with one stone.

Why Chemists Leave The University Laboratory

NOT long ago we commented editorially on the inequality in remuneration which exists between professional and industrial work. We were glad to sponsor the plan suggested by a good friend that there be established fellowships with unusually high remuneration—"to save the exceptional man for educational work." That is, however, only half of the story. A single incident from many will illustrate the other side.

A young professor of analytical chemistry was doing unique and recognized research. His apparatus, such as he had, was begged and borrowed from friends and foundations. His department supplied him with almost nothing. In addition for his analytical course he had sixty platinum crucibles for over a hundred men. These crucibles were loaned to students by the day and had to be returned to him personally each night to be locked in the safe (by order of the department head). Not only did his department give him no funds for research but it filled his time with meaningless routine that was irksome and useless.

This same man subsequently accepted an industrial offer which, incidentally, paid him more than double the salary; but, more pertinent to the immediate question, it gave him unlimited funds for equipment, almost unlimited assistance and complete freedom from the mechanical routine of even ordering apparatus.

The moral back of the tale is this: Industry has a much better appreciation of the intrinsic value of the research man's time and energy than is found in the university. It relieves him of elementary routine, pays him for the quality of his service and gets value received. The job is attractive not only because it pays better, but also because it is free from onerous red tape.

A chemist of parts is not apt to enthuse over a position, in a university or elsewhere, which consumes a part of his time in work that a high school boy would scorn. It is evident that universities may well look toward a housecleaning that will remove the millstones of routine and red tape from the necks of able chemists. Perhaps then the lure of industry and even the shaking of the moneybags will fall upon the deaf ears of the man whose creative impulse is being satisfied

Mass Production of Fundamental Data

SO RAPID has been the advance in the science of metallography that it now embraces far more than is indicated by the derivation of the word. It now embraces the science and art of metals and metal working. Its present importance is only another instance of how modern industrial life has eagerly adapted to its uses the principles discovered by precise physical and chemical experimentation.

Despite the fact that its practitioners devote much of their time to determining the strength, hardness or electrical characteristics of metallic samples, it is unquestioned that rational generalizations are often possible only if proper consideration be given to the constitutional or equilibrium diagram of the alloy system in question. Conversely, a correct diagram is an indispensable guide for a systematic investigation of the possibilities of any alloy series thought to contain members of commercial importance.

As yet we know surprisingly little about these possibilities—due in part to the comparative youth of the science. Excluding those rare metals which are only laboratory curiosities, there are about 600 possible binary systems of the thirty-five or forty fairly common metals. Of these not more than a dozen have been exhaustively studied, and perhaps a hundred are mapped out with fair accuracy. The general outlines of many more have been sketched, but at least 150 have not been touched! Many thousands of ternary systems are possible, and virtually all this field is untrod by the systematic researcher. Quaternary systems—but why continue?

It would be interesting to inquire into the origin of such work as has been done on equilibrium systems. French scientists proposed the principal investigative apparatus, but the Germans have done most, perhaps 80 per cent, of the detailed work. Russian effort has been confined to simple systems. PARRAVANO and his Italian followers have done some splendid work on ternary systems, chiefly of theoretical importance. It has remained for the English to explore a number of binary and ternary systems of great commercial importance, bringing to bear various methods of research in a penetrating examination—in great contrast to the very sketchy, almost hasty, work which characterizes the German publications.

Nearly all of these nations have done more than America. Disregard a large number of careful researches on commercial alloys of narrow composition, and there is little left of a sytematic nature. Perhaps we should not be unduly criticised for thus "skimming the cream." The rewards attending commercial work have been so great that in the past the Americans could afford to let others spend years of patient labor on theoretical problems, while we could apply their conclusions to shop practice.

Bear in mind, however, that practice rapidly adapts theory, and continuous and advanced investigation is essential for technical progress. Hence the importance of intensive work on equilibrium diagrams. We venture to state, though, that if Americans will ever take up the work which perforce has been dropped by Germans and Russians; if Englishmen of ability can be persuaded to continue their searches with the same minute care as before, it appears that some of the principles of mass production must be introduced into the laboratory. Certainly it is of no advantage to stop a tension machine every few seconds to read extensometers, when a movie film can automatically record the entire history of a continuous test, for study at leisure. Like statements are true of thermal analysis, magnetic studies and determinations of a wide variety of physical properties.

A revival in interest in the fundamental diagrams of physical metallurgy therefore seems to await the successful design or combination of instruments of fair precision which work almost automatically. Such a "machine" should contain a furnace chamber approaching black body characteristics, capable of being heated and cooled at definite rates. Its gaseous atmosphere should be under control, and the metallic samples contained therein so connected with auxiliary apparatus that autographic records of various kinds may be drawn simultaneously. All that would be necessary would be to insert the sample, fix the films or charts, and close the switch!

Many of the elements of such a machine are already known. It certainly would be well worth while for some of our institutions possessing good instrument shops to assemble such of them as are available, and to design and construct the necessary auxiliaries.

A New Viewpoint For Labor and Capital

THE typical cartoonist loves to depict a struggle between two huge and ferocious wrestlers—one labeled Capital and the other Labor—while off at one side stands a timorous little figure, afraid to interfere lest he be hurt yet obviously apprenhensive as to his fate should either win—the General Public.

Now the cartoonist may be trite in showing things in this way; but, unfortunately, he is almost always correct. It is almost the universal practice for both sides of an industrial controversy to act as though they alone were concerned. This attitude continues as long as the public at large will stand for it, and it is only when the force of opinion drives our administrators to the verge of drastic action that the rights of the great (or is it little?) third party receive the consideration which they justly should receive.

It is then with feelings of more than relief that we note the recent message of W. G. LEE, president of the Brotherhood of Railway Conductors, to his followers. Mr. LEE points out that there is an amount of damage to the public beyond which capital and labor must not go in their controversies; for, if they do, then the government must, to protect the very life of the nation, conscript their services and force them to fulfill their so necessary functions.

This fact has often been pointed out before. But coming at the time they do and backed by the force of his position, Mr. LEE'S words cannot fail to help drive home to both parties to industrial strife that their wishes alone cannot be the only guide to their actions, and that they must, if they would retain their present independence, consider the effect of these actions on the whole nation.

Report of Sixty-fourth Meeting, Sept. 4-8, 1922 — Council Meeting — Addresses at General Sessions— Abstracts of Technical Papers Presented at the Industrial, Physical and Inorganic, Fertilizer, Rubber, Sugar, Dye and Petroleum Divisions, and Educational, Historical, Cellulose and Leather Sections

EDITORIAL STAFF REPORT

THE Pittsburgh meeting was a good one. It was well attended, the registration running just over thirteen hundred. The provisions made by the Carnegie Institute of Technology were convenient and agreeable, and, as has been the case with every meeting held under the presidency of Dr. Smith, things have gone forward with a certain *cachet* of style, of grace, of dignity, that invariably reflected the captain-general of the hosts.

There were not many startling discoveries noted among the 457 papers presented. That of greatest general interest was probably Thomas Midgley's demonstration of his observations on accelerating and retarding catalysts in the combustion of petroleum hydrocarbons. The rest was, generally speaking, good average, with some peaks.

$25,000 Prize Announced at Council Meeting

The Council of the Society met on Monday afternoon at 3 o'clock in the ballroom of the William Penn Hotel, with President Edgar F. Smith in the chair. In opening the meeting he announced with great pleasure an annual prize of $25,000 donated by the Allied Chemical & Dye Corporation, to be given as a reward to the chemist in the United States who, in the opinion of a proper committee, shall have done most to advance the science of chemistry in the world. It is to be initiated in 1923, and to continue perpetually. The donors desired that a committee should be formed to consist of Dr. Smith and four others to be chosen by him. and this committee is to formulate rules and to organize the first jury of award. This jury is to consist of seven members, of whom five shall be appointed by Dr. Smith's committee and two shall be appointed by the donors; these two, however, are not of necessity to be men connected or associated with the corporation. The prize is available to workers in all fields of chemistry, and to include teaching as well as research.

It was resolved that a special committee draw an appropriate minute of the Society's acceptance and appreciation of this great gift.

Invitations were presented from the San Francisco and Milwaukee Sections to hold the fall meeting of 1923 respectively at San Francisco and Milwaukee, and on vote it was decided to accept the invitation of Milwaukee. It was resolved at the Birmingham meeting in April to hold the spring convention of April, 1923, at New Haven.

Approval was given to a plan for international editorial supervision and control of the *Journal of Physical Chemistry,* hitherto published by W. D. Bancroft, whereby the magazine will be published jointly by the Chemical Society (London) and the American Chemical Society. Neither organization is to be financially responsible for the publication of the magazine, the necessary expense being defrayed by an annual gift of $10,000 by the Chemical Foundation.

The editors of the Society's various journals and the secretary were re-elected. Prof. W. A. Noyes was re-elected editor of the scientific monographs, but Prof. John Johnston wrote that his other pressing duties compelled him to resign from the editorship of the technological monographs. A vote of thanks to Professor Johnston for his admirable work already done was passed and the advisory committee of the Society was delegated to appoint his successor.

The treasurer reported that, owing to reduced costs of paper and printing, he hoped, for the current year, to keep the expenditures of the Society within its income.

Research by Corporations

At the spring meeting in Birmingham action was taken on a motion of Dr. Harold Hibbert to make public the names of those firms and corporations that are supporting research or scholarships at various universities and colleges. Accordingly it was noted that the Grasselli Co., Fleischmann & Co., R. G. Carr of Chicago, the Monsanto Chemical Co., Antoine Chiris & Co., the General Bakelite Co., the Corning Glass Co., the Public Health Institute of Chicago, the du Pont company, the National Lime Association and many others were so engaged. Arrangements were made to obtain and publish a more complete list.

The subject of student members was discussed at some length without any definite action, except that it was recorded as the sense of the Council that the student rate be not increased. These pay $10 a year instead of $15. There are about 1,300 such members of the Society now, and the number of student applicants from Germany and Japan has materially increased of late.

After the meeting the members of the Council re-

paired to the Duquesne Club, where on invitation of the Pittsburgh Section they were guests at dinner. A number of prominent men of Pittsburgh who were not members of the Council were also present. At the close of the dinner short speeches were made by the toastmaster, James O. Handy, who is chairman of the Pittsburgh Section, and the following on whom he called: E. M. Herr, president of the Westinghouse Co., Charles H. Herty, E. R. Weidlein, E. E. Slosson, H. E. Howe, J. E. Teeple, Wilder D. Bancroft, Ellwood Hendrick, and finally as a kind of a cordial and friendly doxology, the president, Dr. Smith.

The General Meetings

The general meeting was called to order by J. O. Handy, chairman of the Pittsburgh Section. After a few introductory remarks, the customary felicitous addresses of welcome were made by S. H. Church, president of the Carnegie Institute, Dr. John G. Bowman, chancelor of the University of Pittsburgh, and Dr. Thomas S. Baker, acting president of the Carnegie Institute of Technology.

Mr. Handy then handed over the meeting to Dr. Edgar F. Smith, who with historical reminiscences and delightful allusions to ancient days, to protons and electrons and to Pittsburgh, the Imperial Daughter of the West (the speaker being first, last and always a Pennsylvanian) he introduced Dr. Charles L. Parsons, who told informally of his tour abroad this summer. He spoke of the International Conference at Lyons, which was its third annual meeting, of the seventy-five delegates present, and of the usefulness of the work carried on by the conference. There is full co-operation among the representatives of various nations. The hospitality dispensed was supreme. Of course the barrier of mixed languages sometimes brought out strange suggestions. Thus, at the formal banquet at the close of the sessions, the official interpreter translated from French into English, and had printed on the invitations, the memorandum as to evening dress in the following words: "Come in your night clothes."

Dr. Slosson's Speech

Following Dr. Parsons came Dr. E. E. Slosson of Washington. We are informed that Dr. Slosson's speech will be printed in full in the *Journal of Industrial and Engineering Chemistry*, and we commend it to our readers as an illuminating discourse on the status of the chemist today. Space forbids us to give more than a few disconnected quotations from his talk that are indicative of the whole.

For instance: "One hundred years ago chemistry was a poem. Today it is a tool." "All sciences earn their own living when they get old enough." "Some want to keep science as a sport, and many fear that the chemist may lose his amateur standing if he makes any money." "The chemist is the greatest coiner of words in the world. Nobody has had such a job since Adam named the animals." "The law of Malthus has been often refuted but never repealed." "Whenever any process is thoroughly understood it is found to belong within the field of physics or chemistry." "The new atom is composed mostly of vacuum with a few algebraic symbols." "The great problem of chemistry is that of combustion. Every tiny grass blade points the finger of scorn at the chemists and says: 'See how we do it!'" Apropos of the solemn dictum of the conferees at Washington to the effect that chemical warfare shall not be, it seemed to spring from the resolution by the home government that "the American Army shall never be sneezed at." "Mind is supposed to be immaterial; and yet it possesses inertia."

So much for his flashes. He concluded with an earnest plea for works on chemistry and chemical phenomena told in non-technical language.

Eliminating the "Knock" in the Automobile Engine

The paper of Thomas Midgley, Jr., and T. A. Boyd on "The Chemical Control of Gaseous Detonation, With Particular Reference to the Internal Combustion Engine," was one of broad appeal to the layman as well as to the chemist. It was sufficiently novel to interest the scientist and yet its utility and commercial significance were such as to attract the industrialist.

The work of the General Motors Research Corporation has had for its purpose the conservation and economic utilization of motor fuel and this particular study is an outgrowth of the problem of developing a more efficient type of internal combustion engine. Were it not for the phenomenon of "knocking," which is well known to every motorist, the simple change from a low- to a high-compression motor would offer a very effective economy in fuel consumption, for by increasing the compression ratio there is a more efficient utilization of the energy content of the fuel. What is but a commonplace annoyance in the ordinary automobile engine becomes so intensified in the high-compression motor that there is not only a serious loss of power but often an actual damage to the engine parts.

The Anti-Knock Compounds

Midgley's investigations have definitely shown that the chemical composition of the fuel is a controlling factor in causing and preventing knocking. An accidental discovery indicated that the addition of a small quantity of iodine to a gasoline fuel greatly lessened the tendency for a higher-pressure engine to knock. It took 2 years of research to discover a second compound having similar properties and about a year more to discover a third. These researches, however, served as a basis to indicate the general nature of the compounds that would accomplish the desired purpose. They also indicated compounds that have the opposite effect—namely, to increase the knocking.

Most of the compounds that affect detonation are derived from about fifteen elements, of which some of the more important are I, Br, O, N, Se, Te, Sn and Pb. Some typical compounds which have been used are iodine, bromine, oxygen, isopropyl nitrite, aniline, diethyl selenide, diethyl telluride, tetra-ethyl tin and tetra-ethyl lead. Bromine, oxygen and isopropyl nitrite are accelerators and the others are anti-knocking compounds. Tetra-ethyl lead, the best of the compounds now known for this purpose, has about 1,500 times the power of benzene in preventing detonation. Recent investigation has shown nickel carbonyl to be an excellent anti-knock and the indications are that the corresponding compound of platinum will probably be even better.

A splendid demonstration of the efficiency of one of these compounds was effected by the experimental explosion of a small quantity of acetylene in a glass apparatus at atmospheric pressure. The addition of but one part of diethyl selenide to 800 of acetylene was sufficient to reduce the loud crack of the acetylene-air explosion to an almost inaudible puff.

But what was perhaps the most striking exhibit was a high-pressure gas engine, completely installed on the lecture platform. By means of a special apparatus[1] connected to the engine cylinder it was possible to measure the detonating characteristics of the fuel. An electric light was so arranged in the circuit that as the knocking increased or decreased the lamp would burn brightly or dimly. When the engine was started and operated with ordinary gasoline a decided knock was distinctly audible throughout the hall. But true to predictions, a benzene fuel mixture did not cause knocking when used under exactly the same conditions. A gasoline fuel that knocked badly ceased immediately after very small amounts of the vapors of iodine or diethyl selenide were permitted to enter the breather of the motor. Similar demonstrations were made to show the efficiency of the other compounds, particularly of the tetra-ethyl lead mixture, which has already attained some commercial significance through its use in airplane and motor-boat engines.

These compounds, however, have not as yet been placed on the market, according to Mr. Midgley, for their full benefit cannot be derived until gas engines have been redesigned to operate at higher compression. The anti-knock compounds give little or no additional energy to a given volume of fuel, so that with the ordinary motor their use will not increase the mileage per gallon of fuel.

The most important aspect of these discoveries from the scientific viewpoint is the increased knowledge and new insight into the theory of catalysis.

Chemical Journalism

E. J. Crane, the editor of *Chemical Abstracts*, had chosen for the subject of his paper "The Journal Literature of Chemistry." He contrasted the exactness with which the scientist accumulates his data with the loose, indefinite and often careless language sometimes used for its presentation. Prof. Wilder D. Bancroft followed Mr. Crane's address with an informal but cleverly illustrated talk on structural colors in feathers. Those who will recall his paper at the Rochester meeting on "Blue Eyes and Blue Feathers" will appreciate the intensely interesting nature of the latest of the good doctor's hobbies.

[1] This is the so-called "bouncing-pin" method described by Midgley at the Birmingham meeting of the A.C.S. See *Chem. & Met. Eng.*, vol. 26, No. 16, p. 735, April 19, 1922, and *J. Ind. Eng. Chem.*, vol. 24, No. 7, pp. 587-93, July, 1922

Dr. Teeple on the Potash Industry

Dr. John E. Teeple was introduced as the man who made an industry, and this he promptly denied. Industries are never created by individuals but by co-operation of a group, each carrying out his function. Potash from Searles Lake was an industry moving slowly about 3 years ago, badly crippled by empirical work badly carried out. The process was sent back to the laboratory for repairs and a set of solubility curves and precipitation diagrams was developed by which it has been possible to increase yields and obtain consistent yields. An intelligent comprehensive investigation includes economic and sales study as well as chemical investigation. This latter should proceed in five steps: Research laboratory work, large-scale laboratory work, small-scale plant (experimental), single unit plant, full-size equipment, large-scale production. Dr. Teeple traced the potash industry through some of these steps and ended by discussing personnel—the difficulty of obtaining a chemically trained man with executive balance.

President's Address

The people of Pittsburgh were the specially invited guests at the session in Carnegie Music Hall on Wednesday evening, when President Smith delivered his address on "Our Science." In a way which is distinctly his own, Dr. Smith held the interest of a large and appreciative audience, who were treated with a brilliant review of the subject nearest our leader's heart—chemistry in America, its history and development.

Cellulose Section

Perhaps it was the stimulus due to the permanent establishment of the division as such that aroused the unusually enthusiastic discussions before the Cellulose Section. The attendance was large and representative, and the technical program was well balanced, including papers of interest to the pulp and paper, viscose and wood-distillation industries and a number of lively discussions on the all-important question of the structure of cellulose.

This latter debate took the form of a symposium on Wednesday afternoon. Dr. Louis Wise presented the views on the subject developed by the work of W. C. Russell and himself at Syracuse University, contending that the structure of cellulose from wood and cotton is the same and offering a hypothesis to explain the prop-

erties and products of cellulose which are generally construed as contrary to this view. E. C. Sherrard expressed opposing views based on the experience of the Forest Products Laboratory. The symposium was conducted by Harold Hibbert, chairman of the division, to whom must go much credit for the lively sessions which have characterized it.

Pulp and Paper Problems

One of the most interesting papers presented was a summary of the research problems in the pulp and paper industry by Edwin Sutermeister, which was read by Dr. Hibbert. The author emphasized the need of the closest co-operation between the research men and the industry if the most value is to be obtained from research. He named as the outstanding research problem the determination of the chemical constitution of cellulose, so that processes may be based on sound principles instead of guesses and empiricism. The nature of hydrocellulose and oxycellulose also needs more attention. More accurate methods of determination and separation should be devised and the extent of their harmful effect on the paper determined. Mr. Sutermeister then took up the problems of each step in paper manufacture by the sulphite and soda and sulphate processes, in bleaching, sizing, bating and coating special papers.

Another talk of interest to paper men was given by Harold S. Davis and described a new apparatus in which the humidity and temperature are easily controlled and in which the changes in dimensions of different samples of paper may be measured under varying conditions. This device is of practical importance in the manufacture of printing papers where the expansion or contraction between imprints may cause blurring.

The rosin sizing of paper was discussed by Alfred Tingle in two papers read by Dr. Hibbert. The reaction between aluminum sulphate and sodium resinate has been studied, and it has been found that when solutions of these compounds are mixed in stoichiometrical proportions, precipitation of alumina and rosin is complete. When a considerable excess of aluminum sulphate is used, the precipitate contains no resinate, but consists of free rosin acids with less than their equivalent of free alumina. At certain concentrations all the alumina remains in solution, rosin acids only being precipitated. Rosin acids precipitated in this way—Rosin B—are not in the same physical condition as when precipitated by mineral acids. Addition of mineral acids to this modification of rosin changes it to the more common form—Rosin A. Rosin B is probably spongy rosin very thoroughly interpenetrated with water. As commonly carried out, the reaction in the beater results in the deposition of rosin in the form of Rosin B on the fiber with less than its equivalent of alumina. Most or all of the remaining free alumina is precipitated as the result of subsequent dilution. That alumina plays no essential part in the sizing is shown by the fact that paper can be sized successfully under conditions such that no alumina can be deposited.

Adsorption of Salts by Cellulose

A most animated discussion was aroused by the symposium on the adsorption of salts by cellulose, which was opened by Wilder D. Bancroft. The significant phenomena in this connection were grouped by Dr. Bancroft under four classes of salts—miscellaneous salts, acids and bases, mordants and substantive dyes. H. B. Williams discussed the action of neutral salts on cellulose, particularly the peptization of cellulose by certain thiocyanates. H. N. Holmes expressed the opinion that the salts present in wood ash are absorbed in the plant and so retain their identity when the wood is ignited. An example of this is the presence of iodine in seaweed. Considerable discussion was aroused on the nature of the action of caustic soda on cotton and the general opinion of those present crystallized into the opinion that this action is one of adsorption rather than chemical combination.

No reports were ready from the committees on analytical methods and on standard cellulose. G. J. Esselen, Jr., reported for the viscosity committee, which submitted specifications for a standard falling sphere viscosimeter which were tentatively adopted and are to be tried out for a year in actual operation and if satisfactory, permanently adopted.

G. J. Esselen, Jr., was elected chairman of the division, with L. E. Wise vice-chairman and L. F. Hawley secretary.

Chemical Education Section

The Section of Chemical Education, of which President Smith is chairman and Prof. Neil E. Gordon is secretary, convened Wednesday morning in one of the largest lecture rooms of the Fine Arts Building, and there was standing room only. It is a very earnest group and those in attendance included eminent teachers who are the true links in the great chain of chemical advancement, old professors with a genius for teaching

BYPRODUCT PLANT OF CARNEGIE STEEL CORPORATION AT CLAIRTON, PA.

whose pupils fill outstanding chairs and occupy outstanding posts in science the world over, young professors with minds quick to sense ideas and to put them to use, and occasionally there are teachers who indicate their vain search for an easy formula for the practice of this most difficult of all the arts.

Pandemic Chemistry

"Pandemic Chemistry" was the first subject, presented by Prof. Wilder D. Bancroft, and it impressed us as the most important paper. He outlined a full course of lectures designed for students who are not majoring in this subject, and also for the general public. It is a course *about* rather than *of* chemistry. The first half-dozen lectures have to do with general principles and important processes and with illuminating experiments, after which he takes up various occupations and industries, and demonstrates the chemical basis of each. It might also serve as a school for the directors of corporations engaged in chemical industry, for goodness knows they need it! We are informed that Professor Johnston plans to establish a course along somewhat similar lines for the benefit of Yale students, while Professor Bancroft is hoping to be in a position to inaugurate such a course at Ithaca.

High School Chemistry in Correlation With College Chemistry

The second paper, by L. W. Mattern, had to do with high school chemistry and its correlation with college chemistry. It is desired that they shall not overlap and that they should be co-ordinated so as to provide for continuous advancement. Right here is where Professor Bancroft's pandemic chemistry is also indicated. The old question what to do with high school chemistry in college will not down. Some colleges require it; others don't. Most of them don't. Then, for freshman chemistry some divide the students into groups of "elementary" and "advanced," which is seldom satisfactory because many of the "advanced" students who have had high school training are not equipped for the advanced course. The discussion ran on for considerable time, and finally a committee of seven was resolved upon to present a report at the New Haven meeting in April. But it stands to reason that a boy who has been taught *about* chemistry in a secondary school will have a better sense of the subject and its scope and meaning than if he has had an inadequate course in the beginnings of chemistry without the vision.

In the afternoon of Wednesday a symposium was held on premedical, dental, pharmaceutical and agricultural chemistry teaching. Prof. J. C. Krantz, Jr., of Maryland State College gave a clear outline of the difficulties of teaching chemistry to pharmacists, and the way to meet them. If pure chemistry is taught, the students are likely to lose interest and study only in order to pass, whereas if the teaching is applied too closely to pharmacy they are disposed to bone up on business and to neglect the underlying theory. He finds that, by setting beacon lights along the way, indicating occasionally the applications of general principles to their prospective work, their interest may be retained and proper study encouraged. Prof. Charles W. Cuno concluded with a paper on "Qualitative Analysis for Engineering Students," and the question was raised whether it was worth while or not. The speaker proposed a course in the chemistry of materials as a substitute.

The Intelligence Test and Freshman Chemistry

Thursday morning Professors Jacob Cornog and Edward Bartow of the State University of Iowa gave a paper on "An Experience With the General Intelligence Test in Teaching Freshman Chemistry." There's no getting away from the correlation between high standing in these tests and high standing in chemistry courses. But in order to bring out the widest possible experience in the subject of mental and general intelligence tests in connection with teaching, it is to be made the subject of a symposium at the April meeting. Someone suggested that these tests helped to determine the competence of teachers, for if students of high standing in intelligence generally fail in their studies, the indication is that the teaching is defective.

Professor Silverman of the University of Pittsburgh reported a remarkable agreement between mental tests and the classification of students. The faculty is not informed of these records until the students have demonstrated themselves. He expressed the hope that some kind of examination along these lines might help to weed out the incompetents at the end of the first semester.

History of Chemistry Section

The Section on the History of Chemistry met in the Fine Arts Building on Thursday. This is Dr. Smith's ewe lamb, and Dr. C. A. Browne of New York and Prof. Lyman C. Newell of Boston University are his fellow shepherds. They are far from being alone in their enthusiasm for this distinguished and cultural side of chemistry, but they are the leaders. Being also active collectors, they have the goods. President Smith left the Educational Section to present two monographs here—viz., on James Curtiss Booth, Chemist, and the Bishop of Llandaff, with a handsome copperplate portrait, his works in four volumes, and an autograph letter.

Dr. C. A. Browne of New York told of John Winthrop, Jr., the first Governor of Connecticut, who was a close friend of Robert Boyle and a fellow member of the Royal Society. He was a chemist of parts, and practiced healing; although not as a physician. Professor McKee of Columbia showed some Dutch cartoons of Van't Hoff. Professor Newell showed letters of Sir Humphry Davy and diplomas signed by John Dalton, and Anton R. Rose showed an unpublished letter of Berzelius to the worthy burgomaster of his town in regard to silk culture.

Division of Fertilizer Chemistry

The Division of Fertilizer Chemistry met on Wednesday, with F. B. Carpenter as chairman and H. C. Moore as secretary.

Fertilizer Analysis Discussed

Many analytical methods for fertilizer testing were discussed. Special emphasis was laid upon the discussion of the Lindo-Gladding method for potash determination in mixed fertilizers as reported by F. B. Carpenter. This method is reported to give results from 0.25 to 0.4 per cent below correct under many conditions, with corresponding injustice to the manufacturer, who naturally desires credit for all of the available potash present. The recommendation of the author that acid be used in solution of the fertilizer to make free all of the available potash was by vote of the division referred to the referee of the Association of Official Agricultural Chemists. It is the hope of this division that the referee on potash may give further attention to this matter and recommend to the A.O.A.C. appropriate action on this erroneous procedure which has been continued for some years despite the fact that attention previously was called to it.

Variation in determination of insoluble phosphoric acid in acid phosphates was discussed by W. R. Austin, who emphasized the discrepancy caused in results from different laboratories by the failure to wash the precipitate thoroughly on the filter with water. In order that variation of commercial significance may not be incurred, it is recommended that a standard sample be included with every lot of tests run so that discrepancies resulting from variations in procedure or unsuspected changes in reagents may not go unnoticed.

E. W. Magruder reviewed methods for determining nitrogen in fertilizer and the discussion resulting made clear the wide variation in practice in commercial laboratories which doubtless is the cause of much of the commercial controversy over valuation of shipments.

Roughly quantitative methods for detection of ten groups of nitrogen-containing compounds were described by G. H. Buchanan of the American Cyanamid Co. The qualitative scheme presented is modeled after the ordinary schemes of inorganic analysis, provision being made for interference of the more common fertilizer constituents which may be present. The ten forms included in the scheme are: ammonia and its salts, cyanamide, hydrocyanic acid and its salts, dicyandiamide, guanidine and its salts, guanylurea and its salts, nitric acid and its salts, thiocyanic acid and its salts, thiourea, and urea.

Influence of Soil Colloids

The replacement of plant food adsorbed by the hydrogels of ferric and aluminum oxides was discussed by Flenner, Lichtenwalner and Gordon, who made careful physicochemical studies of the quantity of plant foods held by these materials. They conclude that the gels hold these materials by selective adsorption, as the material is not washed out, but is subject to replacement as would be expected from adsorbed material. The application of this to soil chemistry was discussed by Wiley and Gordon in another paper on "Can Plants Use Salts Adsorbed by Soil Colloids?" Plants were permitted to root and grow in soils artificially prepared with the maximum adsorption of the various salts used in plant nutrition work. The conclusion is reached that both potash and phosphate are readily available to the plant from the adsorbed form on the gels.

Concentrated Fertilizers Recommended

W. H. Ross, of the Bureau of Chemistry, presented a further discussion of the advantages and limitations of concentrated chemical fertilizers, showing the methods followed by the Bureau of Soils in the study of the problems of how to make a complete concentrated fertilizer from ammonium phosphate, potassium phosphate, ammonium nitrate and similar combinations in various proportions. The need of further research in this problem was emphasized. It was pointed out that the bureau desired not to replace those fertilizers now used but rather to facilitate wider use of fertilizers by development of the concentrated forms, permitting the use of new sources at lower cost and the transportation of materials at less expense to points distant from the source of the materials.

Fertilizers and Plant Composition

The relation of fertilization to plant composition was discussed by H. A. Noyes, who presented experimental data on extended tests in fertilizing grape crops. He showed that from the ratio of the composition from various parts of the plant to each other one can determine the optimum fertilizer use for the specific soil in question.

Utilization of Waste Products for Organic Nitrogen

The afternoon session was opened by a paper written by E. H. Armstrong and read by the secretary, entitled "Utilization of Waste Products for Organic Nitrogen." This paper had to do with the use of such materials as wool waste, leather, hair, shoddy and other nitrogenous materials as fertilizer base. Much of this material was imported from Europe formerly and now it is made here. It goes under the trade name of tankage and contains from 8 to 11 per cent ammonia. Considerable objection used to be made to the material because it smelled of leather waste and some legislation was enacted in various quarters against its use. There exists also a considerable loss in nitrogen content because of the method of treatment.

Special Symposium

The special symposium was begun with a paper by the secretary of the section, H. C. Moore, on the "Modern Trend of Chemical Control in the Fertilizer Industry." Mr. Moore outlined the achievements of chemical control in the three divisions of the fertilizer industry—namely, sulphuric acid, acid phosphate and commercial fertilizers. Some of the triumphs of chemical control in the commercial fertilizer department are not so well known. For example, it has been found possible to select suitable proportions of available material for fertilizer mixtures so that they will not become hard in the bags nor rot the material of which the bag is made.

J. E. Breckenridge followed with a discussion of "Modern Trend of Legislation in the Fertilizer Industry." A number of points were emphasized in this paper: First, the widespread legislation which has been necessary to tax the industry for inspection revenue. Second, legislation against inert nitrogen, and in this, as in most other legislation, the co-operation between the industry and the legislature has been complete and

hearty. Inert nitrogen is, of course, something which is of no earthly good to the consumer and shows up as nitrogen in some analyses. The industry has been alert always to co-operate with the legislature against fraudulent representation of nitrogen content. Specifications are required in most states for mixed fertilizer and in these the details of the specifications must be very complete and according to a prescribed form. Some states legislate that available nitrogen be 60 to 75 per cent soluble, but the legislation on this point is not consistent or even vital. The author pointed out that legislation against special materials was unnecessary, inasmuch as the general fertilizer legislation prohibited the use of any materials injurious to plants and therefore it would be quite foolish to legislate additionally against a specific kind of injurious substance. Mr. Breckenridge finally registered a slight protest against the grading of fertilizer as inferior, passed and good, since the method of analysis did not warrant the so-called "passed" classification, which has a range of only 5 per cent. Two other papers in the symposium were read by the secretary, the first by P. S. Gilchrist on the trend of modern fertilizer plant construction, and the other by E. H. Armstrong on modern trend in fertilizer plant operation.

Division of Sugar Chemistry

The Division of Sugar Chemistry was called to order by Dr. F. W. Zerban, the vice-chairman. The secretary, Frederick Bates, had arranged a thoroughly live program. H. Z. E. Perkins brought to the attention of the section the increasing importance of hydrogen-ion determination as a method of refinery control. Like every other business, chemistry has its fads, and now it is hydrogen-ion concentration. As applied to refinery control there are several points of great interest in the use of the method. The chief use of acidity control occurs early in the process of refining. After washing, the sugar goes through the main process of clarification, bone black decolorization and crystallization without material change in ionization. Many byproducts are formed that are unstable and ferment quickly. Furthermore, they are treated with desiccating agents to complete their destruction. The ionization at these various points is variable, being the resultant of several factors, natural and artificial. The main products of sugar refining are easily tested by means of color indicators, since they are light in color and easily crystallized. With a potentiometer the results are uncertain and sluggish. The byproducts of the main refining operation are dark colored and therefore cannot be tested by means of color reactions. They seem, moreover, to respond somewhat better to electrometric tests. The paper should be regarded as a preliminary report on the subject, but shows clearly that at certain points in the refining operation hydrogen-ion control will be extremely valuable.

Dr. Jackson Confirms His Position on the Clerget Constant

Dr. R. F. Jackson of the Bureau of Standards read a paper on "The Invertase Value of the Clerget Constant." The results given in the paper gave conclusive support to Dr. Jackson's position in this moot question, but inasmuch as there was no one to take the opposite side of the question the paper received none but favorable comment during the discussion.

A paper by F. W. Zerban ably confirmed the earlier work of Dr. Peters on the comparative color determination in cane sirup and molasses. The author showed conclusively that solutions must be filtered through an asbestos layer before carrying out color determinations. Filter paper is not satisfactory, solutions remaining cloudy. This is an extremely necessary correction in procedure.

W. D. Horne described the Vallez rotary filter press and J. F. Brewster brought to the attention of the meeting a vacuum pan for laboratory use.

A New Theory of Char Efficiency

Dr. C. E. Coates discussed activated vegetable chars in some detail and advanced a theory as to the probable reason for the greater decolorizing power of activated material. Activated chars are made from many raw materials, notably lampblack, rice hulls, pine and cypress waste, lignite, bagasse and cane waste. Many experiments show that good char can be made by heating the raw material from 800 to 950 deg. C. with sufficient air to cause considerable surface combustion. A series of analytical results were presented showing that the decolorizing power of a given char varies inversely with its hydrocarbon content. This is an extremely important advance and will lead us a long way toward a proper understanding of the best method for preparing good char. Dr. Coates outlined a simple method of obtaining a cheap char from cane trash.

Inasmuch as it was shown that the hydrocarbon content of char and the decolorizing power have a quantitative and inverse relationship, we are led to a theory as to the cause of greater or less decolorizing power in char. It can be stated that absorption from solution is a selective property of carbon dependent quantitatively on free carbon surface. This surface is wholly or partly covered by hydrocarbon film in chars made without access of air and to some extent by a layer of ash in all chars. The removal of the film by selective oxidation with air and of the ash by means of acid or alkali treatment will expose more carbon surface and increase decolorizing power.

Division of Physical and Inorganic Chemistry

Although apparently we are still distant from a general theory of catalysis, yet there are gradually being accumulated series of experimental results which will be invaluable in the formulation of such a theory when the time comes. That the radiation hypothesis contains elements of truth all who have studied the matter carefully must admit, but whether it is sufficiently general in its application to be regarded as even a first approximation is a matter about which there is still some doubt. Dr. Farrington Daniels after extensive studies of the decomposition of nitrogen pentoxide is inclined to believe that it should be considered in the same way as Berthelot's rule of maximum work, while Dr. Hugh S. Taylor thinks that it is scarcely worthy of any regard. Most people who have studied the matter carefully are waiting for more experimental evidence before either rejecting or accepting this very ingenious hypothesis.

In this connection some studies by Dr. Rodebush of the University of Illinois are not without interest. By the use of statistical mechanics he has succeeded in deriving an equation similar to that developed empirically by Arrhenius for the rate of reaction as a function of temperature. This, combined with the quantum theory, gives a physical basis for Dushman"s equation. By the use of a constant characteristic of

every molecule the validity of the equation is extended so that only the most accurate of experimental data had been found to obey the law.

The study of the hydrolysis of mustard gas on cloth is important and it has been found by R. E. Wilson and E. W. Fuller that in a 2 per cent sodium carbonate solution 3 per cent of sulphonated corn oil was remarkably effective in promoting this reaction. The acid formed by the hydrolysis coagulates the oil into which the mustard gas dissolves and then on stirring the oil drops are carried up into the solution of alkali, where they are again peptized, leaving the mustard gas to be reacted upon.

Catalysts and Catalysis

Taylor and his students, working on various reactions involving contact catalysis, have observed numerous interesting phenomena. Carbon monoxide reacts very differently with copper oxide than does hydrogen. In the reduction by either substance the rate of reaction is slow until a red spot of copper is set free. As the red spot grows in size the reaction is accelerated, suggesting autocatalysis. The same thing also holds for the decomposition of a large number of substances such as calcium carbonate, hydrated salts, silver oxide, etc. R. E. Wilson in the discussion checked this up with the phase rule where the presence of the two phases in intimate contact is required for a truly stable equilibrium. At the point of contact there are different electronic configurations which seem to be important in the mechanism of this reaction. This is also probably part of the explanation of promoter action.

The use of kieselguhr as a support for the important catalyst nickel has been very effective. Hydrogen is adsorbed on the supported material to a much greater extent than on the unsupported. The temperature at which the unsupported material has been reduced is very important; for instance, nickel hydroxide unsupported when reduced at 300 deg. is much more effective than when reduced at 500 deg., but when the material is spread on kieselguhr the temperature of reduction has apparently very little effect. The amount of hydrogen adsorbed by a given sample of nickel varies with the pressure for very low pressure, but soon reaches a maximum depending on the temperature. As much hydrogen is adsorbed at 25 mm. as at 750 mm. at room temperature, according to A. W. Gauger and H. S. Taylor.

BYPRODUCT BUILDING AT CLAIRTON WORKS

A study of the rôle of hydrogen ion in the catalysis has been made by H. W. Close under the direction of H. S. Taylor, and it has been found that the unhydrated hydrogen ion was the effective agent. On dissolving a lactone in ether with 0.1 mol of hydrogen chloride the hydrolysis increased with the addition of water until with an ether solution saturated with water the rate was several hundred times as great as with a water solution saturated with ether, although the electrical conductivity of the latter was the greater. In the ether solution the water aided ionization. There was enough water to produce ionization but not much hydration.

Colloids

E. C. H. Davies read an interesting paper on the effect of gravity, which was small, and of light, which might be great, on the formation of Liesegang bands. When water passes through iron pipes, due to corrosion small amounts of ferric hydroxide hydrosol remain in the water. Filtration through sand will not remove all of the iron. Sulphates and phosphates, added in sufficiently small amounts to be harmless to the water, are not effective in removing this colloid, but with the use of about 0.06 per cent hydroxyl ion the best removal of iron is obtained. Larger amounts repeptize the hydrosol. A convenient method is simply to filter the water through magnesium oxide and then the coagulated iron will deposit on iron sheets. These interesting facts have been obtained by Robert E. Wilson and P. S. Clarke of the M.I.T. Research Laboratory of Applied Chemistry.

A very interesting new and valuable emulsifying agent was described by Harry N. Holmes and D. H. Cameron. *Gum dammar*—be sure to accent the last syllable—is insoluble in water but soluble in many other liquids, aiding in the formation of emulsions of the water-in-oil type where water is the dispersed phase. Such emulsions are more stable and may be made even richer in water than by the use of calcium soaps. By dissolving the gum in a little benzene and mixing into vaseline or heavy oil, salve-like emulsions can be obtained with water. Printer's and lithographer's inks, paints, varnishes and greases can often be greatly cheapened in this way and the properties of the products are frequently better than those of the water-free substance. The use of this emulsifying agent has already been patented.[1]

To obtain a dilute silica gel quickly Lloyd Reyerson and W. T. Morin add ammonia cautiously to the acidified water glass till barely neutral to litmus. A solid gel of half a per cent of SiO_2 may be obtained in this way, while a 2 per cent gel sets almost instantly.

Miscellaneous Papers

At very low temperatures hydrogen chloride and nitric oxide form an intensely purple liquid with a conductivity of 10^{-3} at 130 deg. K., according to Rodebush and Yntema. When the transference numbers of mixtures of sodium and potassium chloride were determined by Schneider and Braley, it was found that sodium had a net transference of zero, suggesting part of the sodium going into a complex anion. By the use of electrometric titrations simultaneously Conant and Fieser and LaMer and Lillian Baker have studied the potentials and energy relations in the reduction of numerous quinones. With a glass-stopped siphon it is possible to obtain reproducible results. Mack and Villars have found that

[1] U. S. Pat. 1,410,012, March 21, 1922.

urease not only aids in the formation of urea but also decomposes it till an equilibrium is reached. R. W. Ryan is studying the tracks of alpha particles through gases under the direction of W. D. Harkins. Silverman and Saunders have studied the formation of ozone from oxygen inclosed in a Berthelot tube.

Anderegg and Bowers describe a new form of discharge obtained by creepage over the surface of various dielectric materials which may have notable influence on the results partly due to the change in the nature of the discharge and partly to be ascribed to the catalytic action at the surfaces. Conclusions are drawn by Anderegg and McEachron after several years of work that the complicating effects of the container walls on chemical reactions in the corona may be more or less serious depending upon conditions and may in some cases cause a complete change in the nature and products of the reaction.

In the study of iron corrosion by water it seemed desirable to R. E. Wilson and D. H. Cameron to study the hydrogen-ion concentrations of buffer solutions at elevated temperatures. This was accomplished after some experimental difficulties with the hydrogen electrode, and the results indicate that there is a slight tendency to shift toward the neutral point. Indicators were found to have similar small shifts of the order of one- or two-tenths of a p_H, so that it may be stated that buffer solutions and indicators are fairly constant up to the boiling point of water.

Leather Section

The meeting of the Leather Section opened with a contribution from Dr. Edmund Stiasny, director of the Institute of Leather Chemistry at the University of Darmstadt, dealing with modern problems in leather chemistry, particularly the chemical nature of collagen, the mechanism of bating and the astringency of vegetable tannins.

Mechanism of Unhairing

In a series of experiments by John Arthur Wilson and Guido Daub, the effects of unhairing by sweating, lime liquors and caustic sulphide liquors were followed microscopically. The action of the sweating process was found to be very similar to that obtained when using an excess of lime with 0.7 grain Na_2S per liter. In both case the cells of the Malpighian layer of the epidermis first separate from the derma and from each other and then liquefy, so that the rest of the epidermis, the hair and the sebaceous and sudoriferous glands are completely separated from the derma and can then be removed mechanically. A decidedly different action was noted with the straight sulphide process using a 2 per cent solution of Na_2S. The protruding portions of the hair and the corneous layer of the epidermis were attacked rapidly, almost complete removal of these being effected before the alkaline solution has penetrated to the depths of the hair bulbs. Consequently when this method is employed the hair bulbs are usually found intact in the finished leather.

Pancreatin as an Unhairing Agent

Some of the fundamental factors in the enzyme process of unhairing were determined by John Arthur Wilson and Albert F. Gallun, Jr. When calfskin is swollen in dilute caustic soda, neutralized with sodium bicarbonate and then put into a suitable solution of pancreatin at 25 deg. C. exposed to air, the hair is completely loosened in 24 hours, but the action is not due to the enzyme, since it is checked by covering the solutions with a layer of toluene. At 40 deg. a solution of pancreatin fails to cause a loosening of the hair of fresh skin (not previously swollen) because the corneous layer of the epidermis is impermeable to the enzyme layer below. When a skin has previously been swollen by acid or alkali, and the corneous layer rendered softer and more permeable, a solution of pancreatin at 40 deg., even under toluene, will not only destroy the Malpighian layer of the epidermis and loosen the hair but it will also dissolve the elastin fibers of the skin, thus effecting both unhairing and bating in a single bath.

Plumping

Two other papers by Wilson and Gallun dealt with the subject of plumping. When the variation in degree of plumping of calfskin was plotted against hydrogen-ion concentration expressed as p_H, two points of minimum plumping were found, one at 5.1, the other at 7.6. From available data, it would seem that these two points represent different forms of skin protein, one stable only in acid solution and the other in alkaline solution.

In the course of this work a convenient method of measuring the degree of plumping was developed. The fact that the tanner tests the skins by pinching, since the resistance of the skin to compression is a measure of the plumping, suggested the use of a thickness gage similar to those used for rubber. The thickness of a given portion of skin is read off on the gage after a fixed time and the ratio of this result to that obtained on the same portion under standard conditions at a p_H of 8 is taken as the degree of plumping. As the instrument is easy to handle, measurements may be made right in the tannery.

Fixation of Tannin by Hide Substance

The fixation of tannin by hide substance was considered from many angles. Wilson and Kern showed the effect of hydrogen-ion concentration upon the analysis of vegetable tanning materials.

The per cent of tannin found by the A.L.C.A. official method increases with p_H value to a maximum at 8 and then decreases rapidly toward zero. On the other hand, p_H value appears to have no effect upon the determination by the Wilson-Kern method over the range 3.6 to 7.3, but the rate of tanning of hide powder decreases rapidly with increasing p_H value above 7. The rate of filtration of tan liquors is markedly affected by change of p_H value, which may be attributed to changing degrees of dispersion of some of the solid matter. The addition of lime to tan liquors causes a precipitation of tannin, but only at p_H values above 7.2.

Wilson and Kern also studied the stability of the hide-tannin compound at different p_H values and found that leather is resistant to washing in neutral or acid solutions, but is broken up into protein and tannin by alkaline solutions. The decomposition begins at $p_H = 7.7$ and proceeds at an increasing rate as the p_H value is raised above this value.

Continuing earlier work on quebracho and gambier, Miss Margeret W. Kelly determined the concentration curves for hemlock, larch, oak and wattle extracts. Using the modified Wilson-Kern method for determining the amount of tannin fixed, all these extracts gave the quebracho type of curve. Miss Kelly also studied the effect of hydrogen-ion and time factors. Fixation is possible on both acid and alkaline sides, the curves showing maxima at p_H values of about 2 and 8, with a

minimum for low concentrations at about 5. With increased time, the minimum at 5 and the maximum at 8 tend to disappear.

Data on the influence of neutral salts were presented by Arthur W. Thomas and Miss Kelly. The results obtained were shown to be due to two effects proceeding simultaneously but independent of each other—the decrease in the dispersion of the tannin with added salt and the increased activity of the tannin due to the hydration of the added salts. In the case of NaCl, the second factor predominates until a concentration of 2 M is reached, beyond which the influence of the first factor is felt. The work is to be continued using $CaCl_2$ and non-electrolyte such as sugar.

Further work by the same authors indicates that there is a difference between tanning fixation on one side of the iso-electric point and that on the other. Between 20 and 25 per cent of the tannin fixed by gelatine at p_H 3 and 5 can be removed by extracting the precipitate with water, whereas practically none can be extracted from the precipitate obtained on the alkaline side. In discussion, Mr. Wilson pointed out that if the character of the leather differs on either side of p_H 5, which is the concentration usually found after bating, then this point is a most critical one.

Dr. Thomas and Alexander Frieden found that the optimum mutual precipitation of gelatine and gallotannic acid took place at p_H 4.4 to 4.6. The optimum points for vegetable tannins were found to vary from 3.5 for gambier and oak to 4.0 for larch, hemlock and quebracho and 4.5 for wattle. At these points the sensitivity of the gelatine: salt test is greatly increased.

Electrophoresis experiments by Dr. Thomas and Stuart B. Foster demonstrated that vegetable tannins are amphoteric, the change in the charge of the electrical particles occurring between p_H 2 and 2.5.

Chromic Solutions

On the basis of electrophoresis experiments Frank L. Seymour-Jones concludes that a negatively charged complex may not be present in certain liquors which do tan. Further consideration of the complex nature of chrome liquors was given by the same author in a paper reviewing the disputed question as to whether the liquor contains colloidally dispersed chromium oxide or basic salts.

Other Papers

Charles S. Hollander described experiments comparing the action of artificial bates with dog manure as used in goatskin puers and with chicken manure as used for calfskin.

Color measurement of vegetable tan liquors was considered by R. O. Phillips and L. R. Brown.

Since free sulphuric acid is not the only objectionable material in synthetic tans, Dr. S. Kohn made a study of the solvent action of various syntans on tanned hide powder. Even at the same p_H the action of different syntans varied considerably.

Gelatine Symposium

Dr. Jacques Loeb's paper on "The Interpretation of the Influence of Acid on the Osmotic Pressure of Protein Solutions" was read by Dr. C. E. Davis.

When osmotic equilibrium is established between a solution of casein and hydrochloric acid inclosed in a collodion bag and an outside aqueous solution free from protein, the hydrogen-ion concentration is always greater in the outside solution than in the casein solution. The observed osmotic pressure is accounted for quantitatively by the difference in concentration of hydrochloric acid in the two solutions, without taking into consideration any possible osmotic pressure of the casein itself. The observed potential difference between the two solutions in millivolts always has the numerical value equal to 59 times the difference in p_H value between the two solutions at 24 deg., proving that the inequality in p_H value is determined by Donnan's equation for membrane equilibria.

Three papers on the program originated in the research laboratories of the Eastman Kodak Co. Dr. S. E. Sheppard presented a very comprehensive study of the characteristics of the plunger type of jelly strength tester and showed how the results obtained with this type could be referred to the twist type as standard.

In a second paper the anisotropic swelling of thin sheets of gelatine was discussed. The swelling was found to be a function of the type of gelatine used. S. S. Sweet worked with Dr. Sheppard in developing the data upon which these two papers were based.

F. A. Elliott read a paper in which Dr. Sheppard and Miss A. Benedict were co-authors, dealing with the preparation of gelatine free from ash and hydrolytic decomposition products. A 5 per cent gelatine solution is electrolyzed for 2 to 3 weeks, then poured into an equal volume of purified acetone. The precipitate is removed, heated to 60-70 deg. C. and made up to a 10 per cent solution, which is cooled on a chill table and dried. The product contains 0.01 to 0.03 per cent ash.

A paper by E. Bateman and G. G. Town was read by Mr. Town. Three series of studies relating to the moisture content of glue were made. In the first, curves were obtained showing the relation between humidity and moisture content, and an exponential equation was developed which holds better than the adsorption isotherm. Second, the tensile strength was shown to drop rapidly as the moisture increased, falling below the value for wood at about 30 per cent moisture. Third, mold growth was found to require 32 per cent or more of moisture, but as the strength is very low in this region, this effect does not become a factor unless the glued material is stored without strain at high humidity.

In conclusion, Wilson and Kern called attention to a curve giving two points of minimum swelling of gelatine, at p_H 4.7 and 7.7. The second minimum is probably the iso-electric point of the sol form of gelatine while the first is that of the gel form.

Election of Officers

Officers for the ensuing year were elected as follows: Chairman, John Arthur Wilson; vice-chairman, Charles S. Hollander; secretary, Arthur W. Thomas; executive committee to consist of officers and C. R. McKee and F. P. Veitch.

Section of Gas and Fuel Chemistry

Initial sessions of the Section of Gas and Fuel Chemistry were held under the chairmanship of Dr. A. C. Fieldner of the Bureau of Mines. The first meeting was given over to a symposium on combustion, at which Prof. R. T. Haslam, W. K. Lewis and others reviewed the physicochemical fundamentals of this subject. Of the fifteen general papers presented at the later sessions, five related to such basic considerations as the constitution of coal and its relation to carbonization and combustion. Technical abstracts of these and other important papers given before this section will be published in a subsequent issue of this magazine.

Division of Petroleum Chemistry

Each successive meeting of the new Petroleum Division is marked by an increasing attendance and a very evident desire to incorporate within this organization all of the varied interests of the petroleum chemist. The change from a section to a permanent division of the Society had been authorized at Birmingham, subject to final approval by the Council of a set of bylaws to be submitted. Unfortunately, a slight indefiniteness in outlining the scope of the division made it necessary for the Council to return these bylaws to the division for amendment and the Council's approval was postponed until its next meeting. In spite of this handicap, however, the work of formulating a business policy, electing officers, etc., proceeded without other delay.

The proposed constitution and bylaws were read by the secretary, Dr. W. A. Gruse, and each section was approved by the meeting. The only change was made in the opening paragraph, which was so modified as to show clearly that the Division of Petroleum Chemistry did not consider within its scope the preparation of standard testing methods and specifications—work which is now adequately handled by A.S.T.M. Committee D-2 and similar agencies.

The following officers were nominated and elected to serve until the meeting in September, 1923: T. G. Delbridge, chairman; Ralph R. Mathews, vice-chairman, and W. A. Gruse, secretary. The executive committee consists, in addition to these officers, of W. F. Faragher and E. W. Dean.

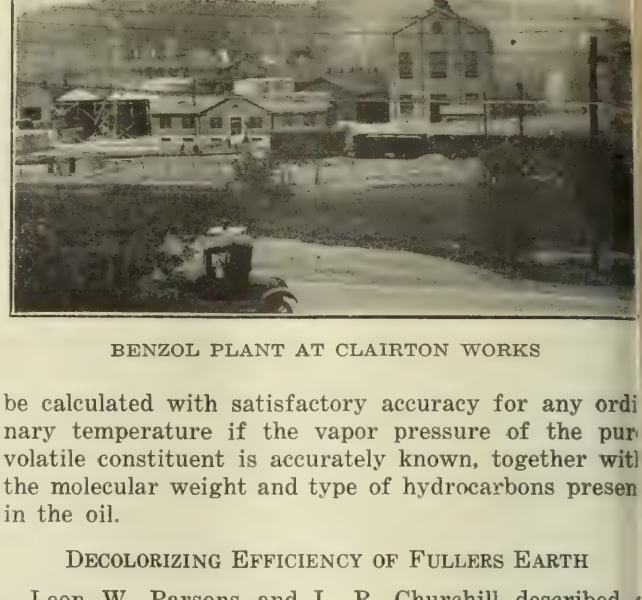
Vapor Pressure and Volatility Measurements

The first two papers to be presented were by R. E. Wilson and his co-workers in the Research Laboratory of Applied Chemistry, Massachusetts Institute of Technology. D. P. Barnard, 4th, discussed the continuation of the work of the Co-operative Fuel Research Program in measuring the effective volatility of a dozen or more motor fuels. Distillation curves were shown for various straight runs and special blends. From the data presented it is possible to draw certain generalizations as to the effect of the shape of these curves on the effective volatility of the fuel in so far as it affects the completeness of vaporization and proper distribution in the manifold.

It was pointed out in the second paper, by Wilson and Wylde, that a knowledge of the vapor pressure of volatile solvents, such as benzene and hexane, dissolved in various types of relatively non-volatile oils is of commercial importance in a considerable number of applications. Of these, the three most important are (*a*) the dilution of crank-case oils with fuels in internal combustion engines; (*b*) the complete renewal of volatile solvents from oils and fats obtained by the solvent extraction processes; and (*c*) the recovery of solvents by scrubbing with cold absorbent oils, as in benzene recovery from coal gas.

The work described in this paper makes it possible to calculate approximate figures for three general types of volatile hydrocarbons—paraffine, naphthene and aromatic—dissolved in most ordinary types of oil.

Molecular weights were determined on all of the oils used, and the amount of vapor pressure lowering for different combinations was compared with the theoretical as predicted by Raoult's law. It appears that the amount of lowering produced by different types of combinations is fairly definitely predictable and that the results for any combination met with in practice can be calculated with satisfactory accuracy for any ordinary temperature if the vapor pressure of the pure volatile constituent is accurately known, together with the molecular weight and type of hydrocarbons present in the oil.



BENZOL PLANT AT CLAIRTON WORKS

Decolorizing Efficiency of Fullers Earth

Leon W. Parsons and L. R. Churchill described a rapid test for determining the decolorizing efficiency of fullers earth. This is based on the vigorous reaction of this earth with pinene to form polymerized products with the development of a very large amount of heat. This temperature rise serves as a convenient and practical measure of the efficiency of various clays as decolorizing agents, provided the reaction is properly controlled. This paper discussed the mechanism of the reaction, the materials used and the application of the test for laboratory and plant use.

Professor Parsons also reported on the progress of his work with Brian Mead in studying the effect of certain properties of emulsifying agents on the stability of oil-water emulsions. It will be recalled that Nujol was used in building up synthetic systems comparable with commercial mineral oil emulsions. It has been found, among other things, that several common emulsifying agents give abnormal results with regard to the type of emulsions produced. This observation has an important bearing on the mechanism of the behavior of soaps and finely divided solids as emulsifying agents.

Engine and Road Tests

The engine experiments reported by Dr. Carl O. Johns of the Standard Oil Co. of N. J. were an attempt to answer the question: Do higher sulphur fuels cause trouble in Diesel motors? Several fuels were tested to ascertain the effect of both free and organic sulphur. This included high-sulphur Mexican crude and gas oils and also a polymerized byproduct from alcohol manufacture containing about 19 per cent of combined sulphur. These were mixed in proportion to give a sulphur content of 10 per cent in the fuel mixture. The Diesel engine was run for about 400 hours at a compression of 500 lb. Another run was made with a kerosene containing 0.85 per cent of free sulphur in solution. Frequent examinations of the dismantled engine disclosed no evidences of corrosion nor was the copper tubing affected appreciably. Some trouble was encountered by excessive carbon formation around the exhaust valve.

Jones and Fieldner, in a paper from the Bureau of Mines, showed the amount of gasoline saved on government trucks after the carburetors had been adjusted by exhaust gas analysis. The adjustments made by

the use of a portable CO_2 indicator gave an increase of over 20 per cent in mileage for the first month after testing and 16 per cent increase for the second month. The average for several thousand analyses from 101 cars showed that after adjustment the completeness of combustion amounted to about 70 per cent.

Prof. Ralph H. McKee exhibited a waxy distillate obtained as an intermediate product in the vacuum distillation of certain oil shales. Usual tests, such as solution in 66 deg. Bé. sulphuric acid, show this product to be highly unsaturated—sometimes as much as 100 per cent. Distillation at atmospheric pressure yields a petroleum containing 48 per cent of saturated hydrocarbons and redistillation brings about additional cracking with a further increase in saturation. In other words, this behavior is apparently the reverse of ordinary cracking, which proceeds with an increase of unsaturated constituents. In the discussion following this paper it was generally conceded by those present that the H_2SO_4 test was without value and that the term unsaturation should not be used, at least without some qualifications.

Refining Petroleum With Hypochlorite

One of the most important papers from an industrial viewpoint was the description by A. E. Dunstan and B. T. Brooks of the use of hypochlorite solutions for refining petroleum oils. This treatment, although often proposed, has usually been abandoned because of the failure to remove chlorine from the finished products. The Anglo-Persian Oil Co., however, has perfected the process and has now entirely replaced the sulphuric acid-caustic soda method in its Persian refineries. The claim is made that gasoline and kerosene are being refined by hypochlorite solutions with losses of less than 0.5 per cent. Malodorous compounds, including sulphur derivatives, are removed and the treated oil is said to be of a very superior quality. The process is carried out in the usual form of treating apparatus and the refining costs are markedly low, especially when polymerization and other losses incidental to acid refining are included in the comparison.

Report of Research Committee

Dr. W. F. Faragher, as chairman of the committee on research appointed at the Birmingham meeting, reported that a study had been made of the comprehensive list of research problems outlined by Dr. Van H. Manning, director of research, American Petroleum Institute, and that the committee had selected a smaller list of problems as the basis for an immediate research program. The following are of the type adapted to co-operative research and are of important and immediate utility to the petroleum industry:

1. Thorough scientific investigation of fractionating columns.
2. Preparation of rational specifications for petroleum products based upon the results of actual research work. More rational volatility specifications for gasoline and tests for the "oiliness" property of lubricants.
3. Investigation as to the actual need of highly refining gasoline for motor fuel; is it necessary to remove bad smelling sulphur compounds completely in order to obtain efficient service from gasoline? Will these compounds injure the engine?
4. A study of the fundamental causes of carbon formation in cylinders; elimination of polymerized products in cylinders; study effect of additions of peroxides, naphthalene, picric acid, phenanthrene, pyrene, picene, cyclohexanol, phenol, etc.
5. Thorough study of lubrication from a colloid chemical standpoint.
6. The chemistry of petroleum hydrocarbons, particularly of the higher homologs.
7. The chemistry of the sulphur, nitrogen and oxygen compounds in petroleum.
8. The chemistry of sulphuric acid refining of oils.
9. The causes and mechanism of color changes in oils.

In a discussion of the committee's report, which was participated in by Dr. Manning and the chief chemists of a number of representative refining companies, it was generally agreed that existing facilities should be utilized in carrying out this research program, but that it should be financed in such a way that its results become the property of the entire petroleum industry.

Lubrication Symposium

A feature of the division's sessions was the symposium on lubrication from the chemist's viewpoint. Prof. C. F. Mabery of the Case School of Applied Science reported the results of his classical study into the fundamentals of petroleum composition, particularly in the fractions that cannot be distilled without decomposition. A second paper on the viscosity temperature curves of fractions of typical American crude oils was presented by Lane and Dean of the Bureau of Mines. The difficulty in interpreting viscosity data at one temperature in terms of viscosity at any other temperature has led to this detailed study over a wide range of temperatures and also to formulating these data in an interpretable form. Dr. Faragher discussed a study made by himself and Ronald Reamer on the frictional coefficients obtained with a Kingsbury oil-testing machine. The symposium was closed with an interesting review by Dr. R. E. Wilson of his published work on the mechanism of partial lubrication.[1]

Division of Industrial and Engineering Chemistry

The Division of Industrial and Engineering Chemistry was called together by the chairman, W. K. Lewis, who at once introduced Dr. L. W. Parsons as chairman of the automatic process control symposium. The first paper, by J. A. Doyle, on the control of industrial heating processes, pointed out that temperature control was only one of the factors in controlling heat, the other was the time factor. In producing a material of given quality and cost, time enters into it fundamentally. Such factors as the surface exposed, the mass, the conductivity rate, the method of applying heat, all affect the time factor. It was well illustrated by a series of diagrams showing where in furnaces of given design the so-called "cold zone" occurs. It was very easy to understand why one furnace would produce material of a different quality than another furnace by simply studying the difference in size and position of this cold zone. The distinct advantage of a continuous process was pointed out in that practically all of the material is subjected to the same kind of conditions and thus quality control is much more rigid and reliable. With batch processes the position in the furnace makes a great deal of difference in the material produced; in other words, material from one part of the furnace will be quite different from the material from another part.

Guy B. Taylor presented a paper on automatic volumetric analysis with particular reference to a carbon monoxide recorder. Dr. A. T. Larson and Dr. Karrer each described some of the control devices employed in high-pressure testing of ammonia catalysts. A machine for automatically controlling the pressure on the catalyst bomb was described in detail and charts for

[1] See *J. Soc. Automotive Eng.*, vol. 11, Nos. 1 and 2, July and August, 1922, and *J. Ind. Eng. Chem.*, vol. 14, No. 8, August, 1922.

its performance were given. It indicated a remarkable performance over a period of days, the pressure holding perfectly constant under operating conditions. The principle of the control was a valve with a core held in place by a stiff spring automatically regulated by means of an electric control. Mr. Karrer's apparatus was a glass pressure gage consisting essentially of a glass diaphragm blown on the end of a tube and automatically recording pressure by means of a bent platinum wire contact. The device must have been quite difficult to make, although the author was modest to the point of disparagement.

The symposium was continued with a survey of the possibility of the recovery of gasoline from natural gas by J. B. Garner. He noted that gasoline content was on the increase in natural gas, it having risen quite appreciably in the last 3 or 4 years. The ideal conditions for absorbing gasoline are under pressure by means of an oil solvent. There seems to be no efficiency at low pressures, and refrigeration is commercially an impossibility. An absorbing temperature of 50 deg. F. for salable gasoline was prescribed. Specifications for the absorbing oil were outlined. It was developed that a paraffine base oil rather than an asphalt base oil gave the best absorbent, and curiously enough a low rate of circulation with high saturation was preferred to a high rate of circulation and low saturation. During the course of a month six volumes of oil were found to be necessary to absorb one volume of gasoline. In the recovery of the gasoline from the oil the gases are first removed, then the oil passes to heat exchangers and finally to gasoline still. There seems to be, in the author's opinion, a fertile field for work along these lines.

The Plastometer Described

Professor Bingham then read a paper on the plastometer as an instrument for process control. He pointed out that many other things were necessary besides chemical control and instanced colloids as an example. For example, what is the difference between a viscous system and a plastic material? Or to put it another way, is the viscosity of a colloidal solution a simple function of the shearing stress? Recent work has shown that this is not the case and that, for example, in a certain paint a change of viscosity of 10 per cent was evident when the shearing stress was trebled. No one class of colloids has this property peculiarly to itself nor is it necessary to have high concentration of the dispersed phase. By the use of the plastometer we can take a material such as paint, which is definitely plastic, and add successive increments of vehicle to the material, measuring each dilution in the plastometer. We then seem to have two well-defined properties, yield value and mobility. Neither of these is quite a linear function of the concentration of solids in the plastic material. One interesting point about the yield value curve is that it approaches a zero value and looks as though we would obtain a concentration of solids which would give zero yield value. This point would be the point at which the material changes from a viscous liquid to a plastic solid. As a matter of fact, the curve bends rapidly toward the zero concentration of solids. A collodial solution will have a definite yield value, whereas a true solution will not. Again, the plastometer offers a method of distinguishing between types of colloids. For example, some colloids exhibit a definite change of properties at a given temperature quite analogous to the melting point of a solid. This is the transition temperature from a plastic solid to a true liquid. Such colloids as glue and nitrocellulose exhibit this property.

Several other papers of interest were presented at the symposium, notably one by Herbert A. Clark on some phases of automatic process control. In it he describes an automatic temperature control with a time control in addition. The temperature was controlled by means of an air diaphragm valve system and over a given time by means of a cam disk on a clock mechanism. Thus a definite temperature can be maintained inside of a kettle or reaction apparatus by controlling the steam input, and this cycle can be repeated at given intervals automatically.

Cost Accounting an Aid in Process Control

The symposium closed with a paper on cost accounting by Charles Wadsworth, 3rd, of *Chemical & Metallurgical Engineering*. The author made a special plea that chemists take up this subject seriously, as executive positions demand a knowledge of it. After discussing the mechanism by which expenditures become cost accounts with the aid of diagrams, the control of production, purchasing and sales by means of costs was outlined. The symposium was then adjourned and the Industrial Division joined with the Gas and Fuel Section in the afternoon at its combustion symposium.

Corrosion of Iron by Natural Waters

The presentation of papers was resumed on Thursday morning, some of the most notable of which we have been able to abstract. Prof. R. E. Wilson presented two papers, one on the removal of small amounts of carbon monoxide from gas streams by passing over granular soda lime, and the second a more notable one on "The Mechanism of the Corrosion of Iron and Steel in Natural Waters and the Calculation of Specific Rates of Corrosion." Professor Wilson first analyzed the chemistry of corrosion and showed that it depended on three reactions. The first reaction was the action of hydrogen-ion on the iron to form ferrous ions and a kind of atomic hydrogen, not gaseous hydrogen nor yet ionic hydrogen. The second reaction was the formation of water from the atomic hydrogen with dissolved oxygen, and the third reaction was the formation of gaseous hydrogen from atomic hydrogen. Obviously the course of these reactions depends a great deal on the hydrogen-ion concentration of the water. If we took extreme cases, the limiting factors of corrosion would vary definitely with the hydrogen-ion concentration. With natural water the second chemical reaction, or the formation of water from hydrogen and the dissolved oxygen in the water, is the controlling reaction. In other words, the amount of dissolved oxygen in the natural water controls the corrosion. With higher hydrogen-ion concentrations, which do not exist in natural waters, other factors enter in and the formation of gaseous hydrogen would be a controlling factor. The fact that in natural waters oxygen diffusion through the liquid layer is the limiting factor can be proved by the fact that the velocity with which the water flows over the corrodible surface changes the rate of corrosion. Professor Wilson suggested a new unit of measurement of corrosion introducing a factor for the oxygen concentration.

Bound up with this same subject was the next paper, by F. N. Speller and V. V. Kendall, in which a method was described for measuring the corrosion of water on iron pipe and an investigation of the effect of velocity

upon the corrosion. An experimental apparatus in which water was passed through pipes ¼, ½ and ¾ in. in diameter was described and the results were discussed. The method will be applied in future to the effect of the composition of the metal, the character of the water, etc. The method used for measuring corrosion was the decrease in oxygen content of the water before and after passing through the pipe.

A preliminary paper on the action of sodium silicate when used in soap was presented by Dr. A. S. Richardson of Procter & Gamble. It was studied from several different angles, notably water-softening action, detergent action without admixture of soap and effect on the emulsification power of soap. Dr. Richardson pointed out that the soap-sparing effect of sodium silicate varied with the conditions of its use, being pronounced at high temperature and in hard water high in magnesium salts. He went on to say that probably of itself sodium silicate had little detergent action except in so far as there was fatty acid present in the wash. There was some discussion on this point and J. G. Vail of the Philadelphia Quartz Co. exhibited some emulsions made from mineral oils with sodium silicate alone. This seemed to indicate that sodium silicate had a detergent action without any fatty acid being present at all.

A short paper by R. T. Haslam and W. P. Ryan on the counter-current digestion of wood by the soda process pointed out that in a counter-current system the decomposition of the wood was much more even than in the batch process, yielding quite properly a high alkali concentration toward the end of the digestion instead of at the start. Diagrams were presented showing the method by which eight digesters could be used in this system.

Additional data were presented by Paul Poetschke on the physical properties of dental cement. The effect of the rate of hardening and the temperature of hardening upon the ultimate hardness of the dental cement was discussed. An apparatus resembling very much a human tooth kept at the temperature of the mouth was used throughout the experiments so as to reproduce actual working conditions. In general it was found that higher temperatures of hardening gave harder cement, but it would be unsafe to go above 130 deg. or even quite that high in the hardening process, as it would be extremely painful and might injure the tooth.

Cheap Wood Alcohol From Methane

Prof. R. H. McKee and S. P. Burke discussed the interesting problem of obtaining methanol, or wood alcohol, from methane. Over 20,000,000 gal. of wood alcohol is produced each year and 10,000,000 gal. in the United States. This in itself is a rather comfortable market toward which to work. Of course it is first necessary to have cheap raw materials, and methane is cheap. It can be obtained in large quantities from natural gas in a very pure state, some gases running as high as 96 to 97 per cent methane. In addition to natural gas, methane can be manufactured cheaply also. Methane is first chlorinated and it will be worth noting that the price of chlorine is the real crux of the whole situation. The methyl chloride so obtained can be produced in fair but not quantitative yields. If now a process is worked out which will utilize the methyl chloride produced in this way without worrying too much about the quantitative transformation, the process is relatively simple. A quantitative change of methane to methyl chloride is next to impossible. The gases, then being a mixture of methane and methyl chloride, are passed with steam over lime at 375 deg. C. The gas velocity is kept down to a relatively low figure and the steam is used in large excess, since the methyl ether which is formed in some quantity from the methyl chloride is changed by means of steam to methyl alcohol. Methyl alcohol is easily condensed out and the residual gases are sent through the apparatus again.

As an alternative it is possible to pass the methyl ether formed as byproduct over aluminum oxide at about 350 deg. and change it into methyl alcohol, although the reaction takes place in steps 50 per cent at a time. It is necessary in this work to avoid iron and copper apparatus and it is also worth noting that even if the hydrochloric acid which is formed is not recovered and sold, it is possible with chlorine at 1½ cents a pound to produce methyl alcohol for 75 cents per gallon, and this allows a generous overhead of 20 cents per gallon. It is further pointed out that $1 is the necessary selling price for methyl alcohol manufactured at present if the producer is to make a profit on the product. The process looks extremely interesting, especially in view of the failing methanol supplies.

Some Objections to Filtration Formulas

Prof. W. K. Lewis pointed out the errors which are inherent in the present formulas for filtration in chamber and leaf presses when sludges which are compressible are used. In Sperry's formula, as follows, $\frac{dv}{d\theta} = \frac{P}{R} = \frac{PA^2}{rvV}$, r is assumed to be a constant for any given sludge, and this is distinctly not so with compressible sludge, because r varies with the fifth power of the voids and obviously for compressible sludges the voids diminish. Professor Lewis suggested some empirical formulas which fitted the actual plant practice fairly well, but he explained that there was no rigid theoretical basis for these formulas, yet they served a valuable purpose in the interim. Among other things which developed from this filtration study is the fact that constant rate filtration is better than constant pressure filtration. The next paper, by M. P. Woodward and W. J. Edmonds, was read by Professor Whitman of Massachusetts Institute of Technology, and discussed the experimental side of compressible sludges during filtration. Several differential equations were derived which may be regarded as fundamental for this type of work.

Paint Consistency Analyzed by the Plastometer

Another extremely interesting paper on the plastometer was read by Henry Green, who has been using it to study the property of paint consistency. This particular property is one of those indefinable things which every paint manufacturer knows and understands, but which have no lower terms or simpler terms by which they can be described. The plastometer offers a very flexible method of attacking this problem. He pointed out that viscous liquids have what is known as a telescopic flow in pipes and it is easy to photograph this telescopic flow and to distinguish it from a flocculated flow which a plastic solid would have. Paints at low temperatures show a solid flow due to flocculation and at high temperatures show a viscous flow. (This would be an additional example of Professor Bingham's differentiation of colloids into those which have a transition temperature, analogous to the melting point from plastic solid to viscous liquid.) The author added a wetting oil to a plastic mass of paint and found that the mixture became a viscous liquid. In other words,

the high wetting oil deflocculated the plastic mass. From these studies it develops that the yield value and mobility, both of which are determined in the plastometer, are dependent, first, on the viscosity of the vehicle; second, on the pigment:vehicle ratio; third, on the force of flocculation in the pigment vehicle system, and fourth, on the particle size of the pigment. The third factor is the most important and, as has been pointed out above, some methods of control and reasons for its behavior have been determined.

Corrosion of Ferrosilicon Alloys

The next paper, by Smalley, on the corrosion of iron-silicon alloys, discussed all of the iron-silicon alloys on the market in this country and in foreign countries and outlined experiments from which the optimum concentration of silicon in the alloys which would give the maximum resistance to acid corrosion could be obtained. The commercial alloys of iron and silicon are solutions of Fe_2Si in iron. The acid resistance of silicon alloys below 14 per cent silicon content is very low, but at 14 per cent it is high and remains almost constantly high until 20 per cent silicon is reached. Many faults in silicon-iron castings are due to slag inclusions and gas bubbles which are somewhat more difficult to get out than in ordinary iron castings. The most persistent concentration of silicon would be roughly 14 per cent, with some manganese present and a little carbon. The manganese in good ferrosilicon alloys, or rather, in the commercial silicon-iron, runs from as low as 0.5 per cent to as high as 2.5 per cent, and the carbon somewhere around 1 per cent or less. Rates of corrosion of various acids were studied and the corrosion of hot hydrochloric acids was found to be much the greatest. Another interesting point was the relatively low oxidation of the iron-silicon alloys at high temparatures when used in heat exchangers, etc.

A paper by Carl S. Miner, J. P. Trickey and H. J. Brownlee on furfural resins created a good deal of interest. The authors had some samples of furfural resins there and amazed some in the audience by the price which they were able to quote. Furfural has always been a very expensive chemical and the resins were therefore prohibitive in price. It is now down somewhere around 35 cents a pound, and is being produced on a commercial scale.

Prof. C. W. Foulk gave a paper on a new form of precision hydrometer, which consisted of a compensated slope and eliminated all the trouble which at the present time arises from certain tensions on the stem of the hydrometer. He has not worked out the commercial possibility of the apparatus, but present indications are that it will have a wide use. Professor Lewis then announced that the papers had been completed with the exception of one or two by title and his own paper on the decomposition of nitrates, which he did not think would be of sufficient interest to read and then deftly adjourned the meeting before anyone had time to contradict him on his own paper. *Sic semper tyrannis!*

Rubber Division

This comparatively young division treated itself to an almost ideal meeting. Our conception of an ideal meeting consists in the presentation of some new fundamental ideas and plenty of discussion of these ideas. In the paper presented by Frank G. Breyer of the New Jersey Zinc Co., data were presented which may affect our ideas on the theory of vulcanization. Mr. Breyer was describing the effect of using a new form of zinc oxide recently prepared by the New Jersey Zinc Co. on vulcanization. This oxide is by average measurement about one-fifth the size of the present marketed product. There is a very large percentage of oxide which is considerably smaller than this average. The effect of this new oxide is distinctly different from that of the normal oxide. This may be due to the average smaller size and it may possibly be due to the percentage of very fine material. The effect seems to be much greater than five times, which is the ratio of size. In compounding rubber with this zinc oxide on the rolls, very much more energy is required to push the oxide into the rubber mix and considerably more heat is therefore developed. Once the mix is compounded thoroughly, the vulcanization or curing is carried out in 30 to 40 minutes as against 150 minutes with ordinary zinc oxide. The tensile strength of this compound is 3,500 as against 2,800. The striking thing about this mix is that when an accelerator is compounded with it in addition to the zinc oxide and sulphur, the curing time is not diminished at all and the tensile strength is increased to 3,800. This is exactly the reverse of our present ideas, for zinc oxide was thought to have only a good reinforcing effect on vulcanized rubber and this new oxide is shown to have an accelerating effect as well. Furthermore, organic accelerators are shown to give additional reinforcing effect with this new zinc oxide.

In addition, this zinc oxide is neutral to phenolphthalein and it is assumed that phenolphthalein neutrality has something to do with the success of this zinc oxide, for when the oxide is sprayed with sulphur dioxide the curing time rises to 4 hours. In other words, it seems that acidic impurities completely nullify any effect which either the size or the neutrality may have had on the vulcanization time. Mr. Breyer advanced a theory to explain this which is not very different from that originally advanced by Ostwald to explain rubber vulcanization, suggestion that it is a physical rather than a chemical phenomenon. This theory was abandoned when the use of accelerators became common, and an elaborate theory of the action of the accelerator has been developed.

Mr. Breyer claims that it is only necessary to state that the zinc oxide has a definite absorptive affinity for sulphur, which affinity is poisoned to some extent by the introduction of acidic impurities. The greater surface of this new zinc oxide and its neutrality both would fit in well with this theory of explaining the acceleration of the curing time.

The Hysteresis of Rubber

Another excellent paper was presented by W. W. Vogt of Goodyear on the hysteresis of rubber. Details of a machine for determining hysteresis loss in various rubber compounds was described. The machine was ingenious and variations were measured by a pendulum throw transmitted from a rotating shaft by means of the rubber compound to be tested. Data were given showing hysteresis loss in rubber when developing 40 to 400 cycles per minute. This is substantially the condition which develops in the field when an automobile is going from 4 to 40 miles per hour. The results are very informing on the physical properties of rubber in tires. It is interesting to note in passing that carbon black shows less hysteresis loss than zinc oxide, which is in turn less than clays.

Bedford and Gray developed a theory for the action of dithiocarbamates and thiurandisulphides which is substantially the formation of zinc salts destroyed in vulcanization. Evidence for this is that excess ZnO aids the activity of these accelerators. D. F. Cranor discussed the temperature developed by certain tread pigments, confirming scientifically some popular knowledge on this subject.

Tearing Test Developed by E. C. Zimmerman

An excellent paper by E. C. Zimmerman on tearing tests described an ingenious and accurate method of estimating the rate of tearing. Another point on vulcanization not known before was brought out by Ira Williams and D. J. Beaver when they asserted that the temperatures developed in vulcanization were much higher than the temperature applied. In other words, the reaction is exothermic. These results were obtained by molding rubber mixtures around steam pipes and inserting thermocouples in the mass. The actual number of degrees rise is not significant, depending on the thickness of layer, radiation, air currents, etc. In an electric apparatus temperatures 40 deg. above the temperature of the heating unit were recorded.

Dr. E. B. Spear called attention to the fact that in using thermocouples the radiation factor must not be neglected, and in another paper with H. A. Endres discussed the limitations which had been discovered to the obscuring power test developed in the Goodyear laboratories.

A number of other interesting papers were read on effect of ingredients in vulcanized rubber, and some excellent pictures were shown on the crystallization of sulphur by H. A. Endres. Reports of committees were heard and progress was recorded.

Division of Dye Chemistry

The most interesting papers read before the Dye Division were two that the authors apologized for as being scarcely technical enough to be presented to dye chemists. As a matter of fact, J. Merritt Matthews aroused the admiration and amazement of the meeting by his collection of batiks and Oriental dyed fabrics and his description of the tedious but effective methods used for their production. Art dyeing is done practically altogether by hand methods and the color is built up on the fabric in accordance with the imagination of the artist. This, therefore, implies that the methods of dyeing must be handled in an understanding way by a craftsman or artist who must be something more than a mere artisan. The principal forms of dyeing employed in art work are the batik style, tied-and-dyed work, stenciling, block printing, spray dyeing and shaded dyeings. The second paper referred to was A. F. Shupp's talk on the laundering of textiles. Mr. Shupp described some of the work at Mellon Institute in connection with the fellowship maintained by the American Laundry Owners' Association, and it was a valuable lesson in the practical importance of the proper application of the right dyes for special purposes. Frequently, it seems, the first trip to the laundry changes a gorgeous "silk" shirt into a ludicrous bundle of rags resembling a battle-scarred flag preserved from the Crimean war and a hotel towel with the inevitable red stripe into a raveled rag with a few discouraged threads replacing the crimson band and making a last feeble effort to hold the two halves together. Popular belief and joke books to the contrary notwithstanding, these unfortunate occurrences are more often due to the improper application of dyes and finishing of the fabric than to maltreatment by the laundryman. The work at Mellon Institute protects the laundry owner from the wrath of his customers by scientifically establishing this fact in many cases where the inferior quality of the goods is responsible for its destruction.

Symposium on Methods for Standardizing and Testing Dyes

From the point of view of the dye chemist, the most important discussion before the division was aroused by the symposium on methods for standardizing and testing dyes. Robert E. Rose, of E. I. du Pont de Nemours & Co., arranged the symposium and led the discussion. Walter M. Scott, of Cheney Bros., South Manchester, Conn., presented a general discussion of various methods for estimating the strength of dyestuffs, including colorimetric comparison, the titanium chloride titration method, the Kjeldahl nitrogen determination method and the estimation of the inorganic salts which have been used in the standardization of the dyestuff. The application of these methods to typical acid, basic and direct colors was shown by tables giving the result of the analyses of several samples of each type. Edward H. Gamble and Robert E. Rose presented a discussion of the titanium chloride titration, pointing out the shortcomings of the method. W. C. Holmes described a method for the direct evaluation of dye in a sample of erythrosine based on the gravimetric determination of the color acid. The excellent results obtained have initiated further work to determine the applicability of the methods to other dyes of the eosine group and to afford evidence regarding their constitution. In the absence of interfering substances, the consumption of acid involved in the precipitation of the color acid is determined by the dye and soda ash present and may be utilized as a convenient means of estimating the latter.

A committee was appointed on methods of standardizing and testing dyes consisting of R. E. Rose, chairman, L. A. Olney, J. M. Matthews, W. M. Scott and J. A. Ambler. This committee will co-operate with the Association of Textile Chemists in this work.

Other Papers

Among the other papers of interest were three contributions from the Color Laboratory, Washington, D. C., by C. E. Senseman and O. A. Nelson, which were read by J. A. Ambler. The papers presented a mathematical treatment of some of the properties of the coal-tar hydrocarbons and intermediates. Truth be told, the majority of the audience was somewhat dizzy after watching Dr. Ambler juggle the Clapeyron equation in calculating the vapor pressures, latent heats and entropy of vaporization of naphthalene, anthracene, phenanthrene and anthraquinone. M. L. Crossley, of the Calco Chemical Co., spoke on the relation of color, constitution and chemical activity of dyes. There was nothing particularly new or startling in anything Dr. Crossley had to say, but it was an interesting survey of the subject and was well delivered by the aid of some beautiful sample charts of dyed fabrics.

Officers of the division for the coming year were elected as follows: Chairman, W. J. Hale; vice-chairman, R. E. Rose; secretary, R. N. Shreve.

Natural Dyestuff Industry and Reserves of Latin America

The Romance of the Natural Dye Industry and Its Struggle for Existence Against the Rise of Synthetic Dyes—Importance of Natural Dyes in Case of War or Other National Emergency

By Otto Wilson

EXCEPT as a reserve Latin America has long since passed its peak of importance as a source of dyeing materials. Its decline has, of course, been due to the same factor that has laid low the indigo industry in India and most others having to do with natural dyestuffs throughout the world—the irresistible advance of the synthetic dyes. The tropical forests of the Caribbean regions are still called upon for certain of their famous woods every year, but the business of gathering and working up most of these materials is in large part an industry of the past. Only a very few have been able to withstand the pressure of the synthetic products and maintain a rather precarious foothold in the world's commerce.

The true rôle of these natural dyestuffs is that which they played in the late war. They form a most convenient reserve on which our dye-using industries may fall back when for any reason the usual flow of the synthetic dyes is cut off. With an American dye industry we are not likely again to be left high and dry as we were in 1914, at least not in the near future.

Importance of a Reserve Supply

Yet that is not an impossibility. It would seem the height of absurdity to suggest that after the pinching times of 1914 to 1916, when, as one writer has said, a man could have sold a section of the rainbow to American dye users if he could have guaranteed delivery, we should calmly permit ourselves to drift back into the same dependence on a transoceanic source of supply for coloring materials as before the war.

When in addition it is noted that through the vastly increased use of explosives and the introduction of gas warfare on a large scale, the chemical industry has become practically the basis of modern warfare, it would seem obvious that national prudence would imperatively dictate the preservation of the dyestuff-manufacturing business. Yet one of the striking features of the after-the-war period is the rapidity with which the hard-learned lessons of the war are forgotten. The protecting embargo against foreign dyes was strenuously resisted in Congress when it was first proposed, and the Senate has recently refused to renew it for another year. It is not impossible that this lesson in chemistry may also fade out of our national memory and the manufacture of our dyes slip back again to German factories. So it is just as well that we keep an eye on our natural reserves. If an emergency again arises—and the day of emergencies is not over—we may again have to turn to our southern neighbors for supplies of colors until we can get our factories to work.

The Romance of Natural Dyes

If the chief future rôle of Latin-American dyewoods is to be that of a reserve, it has not been so many years since they occupied a much prouder place in the colors industry. They have been known to the white race almost as long as the New World itself, and for the better part of four centuries they played a prominent part in the stirring drama of transatlantic commerce. They were among the first of the exports by the early explorers, and in fact their abundance and quality gave a great new impulse to the whole art of dyeing in Europe. When the Spaniards saw the abundance of redwood trees in the tropical Amazon forests, they called the new country Brazil, from *braza*, or fiery red. When the marauding British buccaneers, between raids on the Spanish galleons, settled on the coast of the Spanish territory in Central America to cut logwood in defiance of the King of Spain, they gained for England what is now the colony of British Honduras. The trade was never really interrupted and before the late war Caribbean dyewoods were going to England, Holland, Germany, France and even Russia, although of course in smaller quantities than in former times. The war stimulated production and raised prices immensely, bringing a general revival in several lines of the industry. But when the factories of England, France, Italy and the United States reached full production, the

GENERAL VIEW OF LOGWOOD DEPOTS OF CAPE HAITIEN

A PATH THROUGH THE WOODS IN DUTCH GUIANA

demand dropped off and the difficulty in getting ships further checked the boom. The synthetic dyes are now in the field again in full force and the ax of the tropical woodsman is busying itself more and more with other kinds of trees than those which yield the colored woods.

Logwood

Of all the Latin-American dyestuffs, the one which has put up the most determined resistance to the conquering aniline dyes is the pioneer and leader of them all, the famous logwood. In the early years of the Spanish conquest the exporting of this wood began and its exploitation has continued from that day to this. Until the coming of the synthetic dyes it was one of the leading world sources for coloring materials, and in 1914 it was still holding an important place in the dyeing industry, although losing ground gradually to the artificial dyes. With the shutting off of the German supplies, logwood came into immediate strong demand; exports increased several hundred per cent and prices went skyward. The figures (Table I) of imports of logwood into this country show how greatly the trade increased and how it has dropped off again as our domestic dye industry has developed.

TABLE I—IMPORTS OF LOGWOOD INTO THE UNITED STATES

	Tons	Value
1912	40,030	$511,556
1913	38,277	469,430
1914	40,862	522,434
1915	60,958	832,196
1916	186,816	6,097,576
1917	61,735	1,519,878
1918	29,841	668,141
1919	29,022	549,885
1920	72,830	2,186,860
1921	26,740	636,932

The particular qualities of logwood which have enabled it to keep a place in the dyeing industry against intense competition are thus described by the United States Tariff Commission:[1]

> Logwood is the most useful dyestuff for the dyeing of blacks. It is used for blacks on silk, wool, leather, cotton, fur and straw and in the preparation of inks and color lakes for wall-paper printing. It finds considerable application also as a darkening constituent in grays, tans, browns and compound shades, and has a small use for production of blues. Salts of chromium, copper and iron serve as mordants in logwood blacks. Previous to the introduction of coal-tar dyes, logwood was used in the production of a variety of blues and purples. At present logwood is used almost exclusively in the production of blacks and as a darkening constituent in compound shades.
>
> On animal fibers the underhand solid blueness and overbloom which logwood blacks retain in artificial light have made it the standard black. The synthetic dyes have not been able to duplicate these qualities fully. On wool it offers keen competition to the coal-tar colors. On silk it is the most important black. Silks will absorb over 200 per cent of extract, thus serving as a weighting agent. A properly dyed black on silk increases the durability and resistance to wear and tear. On cotton, logwood blacks are of poor fastness and are used only for cheap blacks in dyeing and calico printing. The sulphur blacks, "aniline black" and certain "'developed blacks" have displaced it for fast shades.
>
> Up to the period of the great war the coal-tar dyes were gradually displacing logwood, due to their lower labor cost in application. In addition certain coal-tar dyes had greater fastness for special uses. The extract manufacturers are meeting this labor cost competition by new extracts which dye and mordant in one operation. Logwood, in common with the other natural dyes, was subjected to the most unscrupulous competition by the German dye firms. It apparently was their intention to annihilate the natural-dye industry.

Logwood, *Hæmatoxylon campechianum linn.*, or, as it is sometimes called in the countries where it is grown, "campeche wood," is a distinctly American product. Travelers in the forests of any section of tropical America, in Mexico, Central America, northern South America and the Caribbean Islands may occasionally come across the low trees, but the favorite growing grounds are in a belt which begins with British Honduras on the mainland and extends eastward over the islands of Cuba, Jamaica and Haiti. The British Honduras wood is said to be the best in quality, but the cost of getting it out, especially as the supplies near the river banks are cut away, have caused the traders in forest products to turn their attention more and more to mahogany and chicle.

The United States gets its supply largely from Haiti and Jamaica. In the former country logwood cutting is still one of the leading activities. One factory formerly worked up about 5,000 tons of wood each year, but it has recently burned and only the logs are now exported. Logwood grows in most parts of the island of Haiti, which includes both the country of that name and the Dominican Republic. In both countries it has been cut away near the seacoast, but great quantities are said to exist, practically untouched, in the interior, and these will become available as highways are built and transportation is made cheaper. Jamaica works up very con-

siderable quantities of extract, using about 45,000 tons of wood a year in her two factories, and logwood extract forms an important item in the trade of the island. In the year before the war clouds broke in Europe Jamaica sent $850,000 worth of the extract to foreign countries, mostly to England and Holland, but also to Belgium, Italy, Germany, France and the United States. We took only about $10,000 worth, as our interest lay in the logwood itself. In 1913 we bought 17,000 tons, having a value of $530,000, out of the total Jamaican exports of 50,000 tons. It is said that the Jamaican industry could be developed so as to meet the full demands of the American dye users for the extract if it should be admitted free of duty.

Manufacture of Logwood Extract

The manufacture of logwood extract is carried on in a number of countries. For the most part these countries make the extract from imported logwood for their own use, but there has been some competition in international trade. England, France and the United States are probably the largest producers. In this country logwood extract has been a factory product almost as long as the country itself has existed, some plants having operated continuously since 1794. In 1914, according to the census figures for that year, nine plants produced 29,000,000 lb. of extract, valued at $1,312,000, a considerable falling off as compared with production at the beginning of the century. There are now eight large producers and several smaller plants. All the factories are on or near the Atlantic seaboard, conveniently close to the source of raw materials.

WEIGHING LOGWOOD, PORT-AU-PRINCE, HAITI

A LOGWOOD FOREST NEAR PIQUORE, HAITI

In manufacturing, the wood is first rasped or chipped into fine pieces or a coarse powder. Formerly this was simply piled in heaps, moistened and allowed to ferment or "cure," but this oxidizing process is now largely carried on in mechanical extractors. The coloring principle, hæmatoxylon ($C_{16}H_{14}O_6$), exists in the wood partly as a glucoside and partly free, and has to be oxidized to form the actual dyestuff,[2] which is hæmatein ($C_{16}H_{12}O_6$).

The uncured chips are placed in an extractor, water is added, and extraction is carried on under pressure. The thin liquid resulting is permitted to settle to remove resinous substances and is then evaporated to a consistency of 51 deg. Tw. It goes into commerce in this semi-liquid form and is also further concentrated to a solid form. By treating the extract with oxidizing agents, a substance called hæmatin extract is formed, which when evaporated forms hæmatin crystals. Logwood extract with iron or chromium mordants yields a black dye and with alumina or tin violet blues and grays.[3]

Fustic

Second only to logwood as a natural dyestuff is fustic, or old fustic, as it is sometimes called to distinguish it from young fustic, an entirely different wood. Botanically it is known as *Chlorophora tinctoria* (Gaudich), or *Morus* or *Maclura tinctoria*, and in the countries where it is grown it goes by the name of Cuba wood, yellow wood, palo amarillo or fustic. It is closely related to the osage orange that grows in this country. In fact the latter was substituted for it during the war when shipping conditions prevented importation from the West Indies.

Fustic wood is the source of a yellow dyestuff used as a distinct dye and also with other dyes for obtaining compound shades. With aluminum and tin it yields a bright yellow color and with iron and copper various olive shades. In general these colors are only indifferently fast to light, but with chromium as a mordant olive-yellow and old-gold colors are obtained which are said to be fast to both light and milling. Fustic colors were formerly widely used for dyeing wool, and they are still of much importance, although they are being more and more displaced by the coal-tar colors, which are said to be cheaper to apply and more fast. In wool dyeing, the chief mordant used is potassium bichromate and it is usually employed, on both wool and silk, in combination with other dyes to produce various shades of olive, brown, drab, etc., and in the shading of blacks. In cotton dyeing, fustic has had extensive use in coloring khaki cloth for tents and uniforms.

The "old fustic" tree is a native of the same tropical forests of America as logwood and its occurrence is about as widespread. Brazil, Colombia and Venezuela in South America; Honduras, Costa Rica and Panama in Central America; the lowlands of Mexico and the islands of Cuba, Jamaica and Haiti, all claim the fustic tree as a native product. The best wood comes from the Tampico district in Mexico and from Cuba, that from Brazil and Jamaica being regarded as of lower

FUSTIC LOGS READY FOR SHIPMENT

quality. The trees grow 60 or 70 ft. high and the wood is very heavy. Only the heartwood is used for dye-extracting purposes. A feature that materially increases the cost of bringing the wood to the market is that the trees are scattered thinly through the forests and are not found in groves like logwood.

Fustic wood has two coloring principles,[4] morin ($C_{15}H_{10}O_7\,2H_2O$) and maclurin ($C_{13}H_{10}O_6$), with quite distinct properties. In preparing the extract for dyeing, the wood is chipped and an extract obtained in the same way as from logwood. To separate the morin from the maclurin the extract is treated with a little acetic acid and then with lead acetate solution, causing the morin to precipitate as a yellow lead compound and leaving the maclurin in solution. By further treatment of this precipitate crystals of crude morin are obtained while crystals of maclurin are separated from the original solution. Both crystals are in the form of colorless, or almost colorless, needles. Maclurin is rather more soluble in water than morin.

Young fustic, *Rhus cotinus linn.*, is a native of Europe and the West Indies, and was used in Europe before old fustic was known. It also yields a yellow coloring matter, called fisetin ($C_{15}H_{10}O_6$). Young fustic is little used today, as its colors are not fast.

Annatto

A dyestuff which is now little used in coloring fabrics, but which is of considerable value for coloring butter, margarine, oils and cheese, is annatto, or "arnotto." It gives an orange-red color which is very fugitive to light, but which resists soap and acids very well. When it is used at all for dyeing cotton, it is dissolved in a boiling solution of carbonate of soda, while for silk the same chemical is used half and half with annatto. When used with alumina as a mordant, annatto forms an orange lake and with tin a lemon-yellow lake. In acid solutions it yields a red color. It is partly soluble in water and more soluble in alcohol and alkaline solutions.

Like logwood and fustic, annatto grows in the islands of the Caribbean and in the lands that border that sea on the south and west, as well as in northern Brazil. Its use antedates even that of logwood, as the natives who greeted Columbus and the later adventurers from Spain used it to paint their faces and bodies. It is cultivated in many parts of the West Indies and in the Guianas and other parts of South America. In the country around Port Limon, the Caribbean port of Costa Rica, annatto plants are said to grow abundantly and there is an opportunity to cultivate them for commercial purposes. Our supply comes in large measure from Jamaica, where continued cultivation has made it an item of some importance in the export trade.

The annatto plant, *Bixa orellana linn.*, is a small tree or shrub growing 8 to 12 ft. high. The coloring matter comes from a reddish waxy pulp which covers the seeds. Full crops are not gathered until 3 or 4 years after the seedling plants have been set out, the yield then being about 500 or 600 lb. of seed per acre, the amount increasing for several years. In Jamaica the growing of the annatto and the gathering of the seeds is almost wholly carried on by the peasant class, the women and children for the most part attending to the gathering and drying of the seeds when the miter-shaped capsules in which they are contained split open. The waxy "testa" of the seeds is removed by stirring the seeds in boiling water, and after some days it is passed through a sieve. The liquid is permitted to stand for a week or so to ferment, the dye material meanwhile settling to the bottom. The clear water is decanted off and the residue is evaporated to a putty-like consistency and shipped in rolls or casks, reaching the market as a thick paste or in dry cakes. It is possible to remove the pulp from the seeds and prepare a dyestuff for market without fermentation. The best annatto comes from the Guianas and contains 10 to 12 per cent of the pure dye.

The chief coloring matter of annatto is called bixin. It can be crystallized from a chloroform solvent into brown-red or deep-red rhombic crystals. In this form it is fairly soluble in chloroform or alcohol and less soluble in other common solvents. It dissolves in concentrated sulphuric acid to form a cornflower-blue liquid. The formula for bixin is in dispute,[5] different authorities giving it as $C_{28}H_{34}O_5$, $C_{25}H_{34}O_5$, $C_{27}H_{32}O_4$ and $C_{26}H_{30}O_4$.

Brazilwood

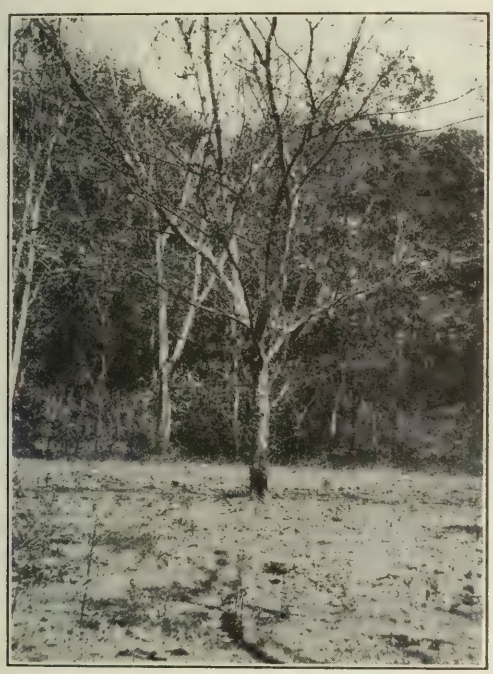
Most noted of all the Brazilian dyestuffs is the famous brazilwood, which has been known practically since the discovery of the country, but which is now of little commercial importance. This is one of a number of redwoods, of which there are two classes—soluble and insoluble. The Latin-American redwoods come under the former classification and are species of the genus *Cæsalpinia*, the four most important in America being brazilwood, Pernambuco wood, peachwood and limawood, although the term brazilwood is sometimes applied to all the woods of this class. The true brazilwood, *Cæsalpinia brasiliensis*, is very plentiful in the forests of the north. It is brick-red inside and brown-red on the surface, and is very hard. It is found only in Brazil, although the other species of *Cæsalpinia*, especially limawood, occur throughout the forests of Central America and other tropical regions.

Brazilwood extract is called "hypernic" and is obtained in much the same manner as logwood extract. It is sold as a 51 deg. Tw. extract and as a solid. Its coloring principle is brazilin ($C_{16}H_{14}O_5$), which crystal-

[4] Perkin, A. G., and Everest, A. E., "The Natural Organic Colouring Matters." London and New York: Longmans, Green & Co., 1918.

[5] Perkin and Everest, "The Natural Organic Coloring Matters."

zes either as colorless needles containing $1\frac{1}{2}$ H_2O or as olorless prisms with $1H_2O$, and is readily soluble in lcohol and water, as well as in a dilute solution of bdium carbonate, in which it gives a beautiful carmine-ed color. Brazilin is changed by oxidation to the ctual coloring matter called brazilein, a reaction which akes place readily on exposure to the air. Brazilein orms dark needles of a gray metallic luster, freely oluble in hot and slightly soluble in cold water. With luminum salts it forms a red color lake. On wool it ields brown or reddish-brown shades with bichromate, lue shades with sulphate of alumina and scarlet with tannic chloride. The colors yielded by brazilwood ex-ract are fugitive and its principal present use for extiles is as a reddening constituent to modify shades



A FUSTIC TREE

of other natural dyes. When used alone, its chief employment is for dyeing leathers dark red and red-chocolate.

Of the other redwoods mentioned, Pernambuco wood, *Cæsalpinia ciesta,* is the richest in coloring matter, containing about twice as much as brazilwood. It is abundant in Jamaica and Brazil. Peachwood, *Cæsalpinia echinata,* is found in Mexico and Central America.

Indigo

The America species of the indigo plant, *Indigofera anil linn.,* is widespread throughout Latin America, from Brazil to Mexico, but it has been little cultivated in recent years. Before the discovery of synthetic indigo the cultivation of the plant had reached important proportions in some countries. Venezuela records an exportation of 1,800,000 lb., worth $2,250,000, as far back as 1802, but the growing coffee industry attracted the attention of planters and indigo cultivation was gradually abandoned. Today the plant grows everywhere as a weed and is little utilized.

The only country in which the indigo plant has furnished important supplies for export in recent years is Salvador, where cultivation on a considerable scale has been maintained for a long while. In 1910 that country sent to Europe and the United States $314,000 worth of indigo, but the trade dropped to $55,000 in 1913. There was an increase in the next year to $98,000, of which England took the largest share, $32,000, the United States following with $20,000. Then came the war and the industry boomed, exports going as high as $600,000. Since the war production has fallen back. Colombia also sent us a few thousand dollars' worth during the war, but exports stopped when our factories became fully active. Costa Rica sent a small amount in 1919, and there is said to be some manufactured in Guatemala. Mexico in 1918 exported considerable quantities to Spain and Japan.

Cochineal

A natural dyestuff for which the world is indebted to Mexico is cochineal, the once important red color obtained from the insect *Coccus cacti.* This has been used for centuries in its native country, and from there it was early taken to the Canary Islands, Java and other parts of the Old World. It is the only important dye derived from animal life. The insects feed on a particular variety of cactus which grows wild naturally but is cultivated for the sake of its tiny guests. Only the female insects are used for making dyes, as they do not have wings and remain on one part of the plant. They are brushed off before the beginning of the rainy season and are killed either by being placed in an oven or by the use of hot water or steam. When the former process is used, a silvery down is preserved on the body of the insect and the resulting color is known as "silver gray" or "silver cochineal." When hot water or steam is used, the resulting color is dark, red or brown, and a product known as "black cochineal" results. No other preparation besides grinding is necessary before the cochineal is used as a dye.

Cochineal dyes were formerly in wide demand, but like most other natural coloring matters, they have practically yielded the field to the coal-tar products. They were little used for cottons, but were extensively employed on silks and woolens. On wool they give a fiery scarlet when mordanted with stannous chloride, oxalic acid being added to the bath, or with special preparations of stannic chloride. Wool mordanted with aluminum sulphate and tartar and then dyed in a separate bath with cochineal takes on a crimson color, and with ferrous sulphate and tartar, purplish, slate or lilac colors are produced. In dyeing silk crimson, alum or tin mordants may be used, with cream of tartar and oxalic acid. The artificial azo-scarlet dyes are now largely used in place of cochineal on textiles. To a limited extent cochineal is used as a coloring matter for foodstuffs, candies and face powders.

Miscellaneous Colors

Other dyestuffs of the Latin-American countries which have been or might be used are numerous, but there is small prospect that they will become of importance to foreign interests. The forests of Brazil[6] contain a considerable variety of dyewoods and other color-producing plants, practically all of which are now of either historical or purely local interest. In foreign markets they have little chance, but there is a limited

[6]At a cotton congress held in Rio de Janeiro in 1916 Dr. Miguel Calmon, chemical director of the Companhia Industrial do Brasil, gave an address on the use of native vegetable dyes. This address does not seem to be available in the United States, but those wishing to follow up the subject can probably obtain full information by addressing an inquiry to Dr. Calmon in care of the above company.

field for them in Brazil. That country has an important cotton-growing and cotton-manufacturing industry, both of which are receiving much encouragement from the government, and as the output of cotton cloth increases, more and more interest will naturally be taken in developing the native dyestuffs. There are already dye factories in Minas and Cubatão, and the chemists of the country are fully alive to the possibilities of its resources in color materials. In current books on Brazil mention is made of dyes from "inglotina," made from mangrove leaves; two anils, *Cissus tinctarea* and *Cissus sicyoides*, which are said to give fine blue colors; indigo; some fuchsias which give a black; and other trees which yield a brilliant yellow. Annatto grows in most parts of the country.

In Venezuela, besides fustic, brazilwood, annatto and indigo, there are several plants known locally for their coloring properties. A tree called "amarillo," *Aspidosperma vargasii*, belonging to the family of the dogbanes, has a bark which gives a yellow dye and some tannin. The bark of the onotillo tree, *Vismia ferruginea*, of the St. John's wort family, also gives a reddish-yellow, resinous substance, which can be used like gamboge. Two others yield a yellow or yellowish-red dye. They are known as "rasura de cucharo," *Condaminea tinctorea*, and "bosna" bark, *Zanthoxylum ochroxylum*, the latter containing berberidine. Red mangrove bark, *Rhizophora mangle*, yields a red pigment which can be used for coloring leather.

Mexico has a wide variety of color-bearing plants. One said to be highly regarded by dyers is *Reseda luteola*, which gives a yellow coloring principle "luteolina" ($C_{15}H_{10}O_6.2H_2O$). Other plants yielding yellow dyes are yellow or Cuba wood, malacate, curcuma or camotillo and several varieties of azafran and azafrancillo. Among those which give blue coloring materials, besides indigo and related plants, is one known locally as "muitle." A number of others yield red dyes and from a few are obtained materials for coloring fabrics green and black.[1]

Washington, D. C.

Legal Notes

By Wellington Gustin

Buyer, Committing First Breach of Contract, Cannot Sue for Seller's Subsequent Breach

In the case of Dawson Cotton Oil Co. versus Jones, the company sued E. & F. G. Jones for damages for a breach of contract for failure to deliver about 57 tons of product of 100 tons contracted for. Defendant pleaded that the company before the time fixed in the contract for final delivery, being fearful that the market price would decline, called upon it to make immediate delivery of the remaining 57 tons or give a further guarantee that the product would be delivered; then, it alleged, the company by its agent refused to accept a carload then being loaded and gave notice that it would accept no more under the contract.

In short, the defendants contended that the company first breached the contract by refusing to accept a carload and notifying them that it would accept no more of the product, all before the expiration of the time stated in the contract for delivery. This plea the Supreme Court of Florida has held to be a valid defense to an action on the contract for breach for failure to deliver according to its terms. The seller averred that the buyer committed the first breach by refusing to accept, which, if true, the Supreme Court holds to be a good defense, reversing the trial court's judgment.

This contract was in the form of a letter by the Dawson Cotton Oil Co. to E. & F. G. Jones, signed by an official of the company and accepted by E. & F. G. Jones. Among other things it provided for delivery in October, November or December following, at option of the seller; shipment made with buyer's privilege of inspection; and should there be any dissatisfaction as to the grading of the peanuts, it should be "left to the regular rules of arbitration, and the party whom it shall be decided against shall pay all costs."

Measure of Damages for Failure to Deliver Under Contract

In an action brought by H. P. Pearl & Co. against the Packard Iron & Metal Co., plaintiff sought to recover damages for a breach of contract for the non-delivery of a carload of iron. A judgment was rendered on trial for plaintiff, and defendant appealed to the Court of Appeals of Maryland, where the judgment was affirmed. (115 Atlantic, 761.)

The Court of Appeals held that in an action for damages for non-delivery of the iron, evidence as to its market value during the month wherein delivery should have been made was admissible, in view of the uniform sales act, providing that where there is an available market the measure of damages is the difference between the contract price and the market price at the time when the goods should have been delivered.

Provisions of Uniform Sales Act

Damages for failure to deliver goods as provided in uniform sales act, are set out as follows:

"(1) Where the property in the goods has not passed to the buyer and the seller wrongfully neglects or refuses to deliver the goods, the buyer may maintain an action against the seller for damages for non-delivery.

"(2) The measure of damages is the loss directly and naturally resulting, in the ordinary course of events, from the seller's breach of contract.

"(3) Where there is available market for the goods in question, the measure of damages, in the absence of special circumstances showing proximate damages of a greater amount, is the difference between the contract price and the market value or current price of the goods at the time or times when they ought to have been delivered; or, if no time was fixed, then at the time of the refusal to deliver."

Opinion on Similar Point in Another Case

On a similar point in an Illinois case, Summers vs. Hibbard, 46 Am. St. Rep., 872, the court says:

"There is no doubt of the correctness of the rule stated by appellants that, where delivery is required to be made by installments, the measure of damages will be estimated by the value at the time each delivery should be made."

[1] A full account of several dye-plants of Mexico will be found in a pamphlet (in Spanish) of thirty-eight pages entitled "Las Plantas Mexicanas y Algunas Exoticas Productoras Colorantes," by Juan Manuel Noriega, issued by the Government of Mexico in 1919.

Electrical Characteristics of Dry Cells—II*

By G. W. Vinal and L. M. Ritchie

Explaining the Behavior of a Dry Cell in a Circuit and the Effect of Internal Resistance, With Equations and Curves—Grouping of Cells Is Also Discussed and Diagrams Are Drawn

In PART I of this paper, on the characteristics and testing of dry cells,[1] are given a discussion, tables of data, and curves showing the effect of temperature on the voltage, short-circuit current and service capacity. With a rise in temperature the coefficient for the voltage, current, deterioration of cells on the shelf and at low current drains becomes positive. Capacity of the cells, which is usually measured as days or hours of service, is also expressed in terms of ampere-hours and watt-hours. The measurements are made by constant resistances on continuous and intermittent discharges and by constant current on continuous discharge. Curves of the most reliable data are shown which will permit the calculation of the capacity at different rates of discharge to a number of end points. Examples are given showing the method of reading the curves and computing the results.

This second article deals with the theory of dry cell behavior in an electrical circuit, including the effect of grouping, internal resistance of the cells, and other circuit characteristics.

Behavior in a Circuit

By the open-circuit voltage of a dry cell is meant the electromotive force of the cell when it is not producing any current. Such a measurement can be made on a potentiometer. If a resistance is connected across the terminals of a cell, a current will flow through the circuit from higher to lower potentials—that is, it flows from the carbon to the zinc. The current, however, does not begin with the carbon and end with the zinc, but flows through the cell also. It is evident, then, that within the cell the current flows from the electrode of lower potential to the electrode of higher potential, being made to do so at the expense of the chemical energy of the cell.

If a potentiometer be used to measure the potential difference at the terminals of a cell when it is discharging through an external circuit, it is found that the voltage measured is less than for the cell on open circuit. Designating the open-circuit voltage of the cell by E and the potential difference at the terminals of the cell by E' when a current I is flowing through an external resistance R it is found that:

$$E' = IR \qquad (1)$$

That is, Ohm's law is here applied to the portion of the circuit which is external to the cell. The difference $E - E'$, therefore, represents the voltage drop in the cell itself. Since the current is the same in the cell as in the external circuit Ohm's law shows that:

$$E - E' = Ib \qquad (2)$$

where b is a quantity that represents the internal resistance of the cell.

Adding equations 1 and 2 the general expression for Ohm's law as applied to the entire circuit becomes

$$E = IR + Ib$$

or

$$I = \frac{E}{R + b} \qquad (3)$$

The total resistance of the circuit is the sum of the external resistance of the circuit and the internal resistance of the cell. For the ordinary dry cell, when fresh, b is a small quantity and may usually be neglected in comparison with R, but as the cell is used up b increases and I decreases. When the cell is no longer able to perform its service, it will be found that while E has decreased somewhat, b has increased to many times its initial value.

The maximum current which a cell can deliver is, by equation 3, putting $R = 0$:

$$I = \frac{E}{b} \qquad (4)$$

In making measurements, R cannot be made exactly zero, since the shunt and lead wires of the ammeter must necessarily have some resistance. This resistance, however, can be made very small. In standard practice it is 0.01 ohm. When $R = 0$, or nearly so, the value of I is called the short-circuit current of the cell.

Electrical power is the rate of expenditure of electrical energy and is measured in watts. The watt is the power when a current of 1 amp. flows through a resistance of 1 ohm. Consequently the number of volts multiplied by the number of amperes equals the number of watts; or, in general

$$IE = P$$

The power derived from the cell at any time is, therefore, the product of its electromotive force E by the current which flows, I. Part of the energy is expended in the cell itself and part in the outside circuit. Since the current is the same throughout the circuit the expressions for the power expended in the battery and outside of it are obtained by multiplying I by the fall in potential in each part of the circuit. Inside the cell, this is

$$(E - E')I = P_1 \qquad (5)$$

Outside the cell, it is

$$E'I = P_2 \qquad (6)$$

Referring to equations 1 and 2, the values for $(E - E')$ and E' in terms of current and resistance are obtained. Substituting these in equations 5 and 6 and at the same time adding these equations

$$P = P_1 + P_2 = I^2b + I^2R \qquad (7)$$

Assuming that $R = 0$ or is nearly so, I^2R also equals zero, leaving the equation for the power expended

$$P = I^2b$$

This means that when the cell is delivering its maximum current (equation 4), all the power is expended in the cell itself and is dissipated in the form of heat. Although 25 amp. or more may thus be drawn from the cell, the current does no good except to indicate the condition of the cell. On the other hand, equation

*This paper is taken from Chap. IV of the forthcoming circular 79 of the Bureau of Standards on Electrical Characteristics and Testing of Dry Cells. Published by permission of the Director of the Bureau.

[1]See *Chem. & Met. Eng.*, vol. 27, No. 11, p. 546, Sept. 13, 1922.

7 shows that for any value of I which may be desired the smaller b is the less power is wasted in the cell itself. For this reason a small value of b is desirable. The equation also shows that the power expended in the cell increases as the square of the current flowing, which indicates that the importance of making b small in cells intended for ignition and heavy duty is greater than in the case of telephone and light-service cells. Certain practical limitations enter in fixing the resistance of the cells which show that excessive short-circuit currents are not a desirable feature.

Some dry cells which in the beginning show excessively large currents on short circuit may increase in resistance so rapidly that they will give less service than other cells of the same size, but having smaller initial currents. The tendency in this country toward cells of very large flash currents has been partly due to a mistaken idea that the more current that can be drawn from a cell the more service it will render. European cells generally are higher in internal resistance than American cells.

Internal Resistance of Dry Cells

From what has been said above about the resistance of the cell, it might be implied that b is a definite and constant physical quantity. Such, however, is not strictly the case. The resistance of a cell is ordinarily

$$\frac{E - E'}{I} = b \qquad (8)$$

but it can easily be shown that for various values of I different values of b are obtained apart from any consideration of polarization phenomena. By experiment it is found that the larger values of b correspond to the smaller values of I, but that for the currents ordinarily required of a dry cell the values of b are small and do not change very rapidly with changes in I. The practice of a few manufacturers to state the internal resistance of their dry cell to the thousandth part of an ohm is not to be commended, if it means nothing more than the open-circuit voltage divided by the short-circuit current, and it does not represent the resistance of the cell under working conditions.

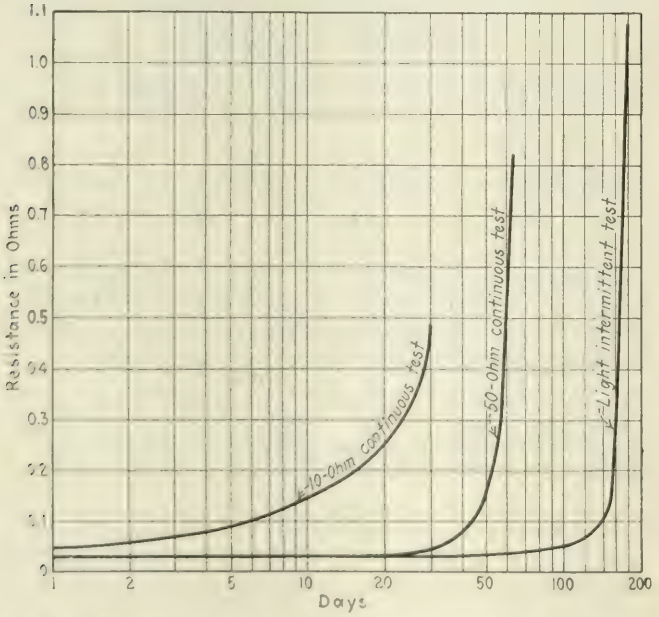


FIG. 10—PROGRESSIVE CHANGES IN RESISTANCE OF DRY CELLS MEASURED BY AN ALTERNATING-CURRENT BRIDGE IN SEVERAL TESTS

When the cell is new, the resistance b is ordinarily small, but it increases with the age and use of the cell. This is not due to the drying out of the cell by evaporation as is often supposed, although that may be a minor cause. The reactions of the cell due to the passage of electric current result in the formation of double chlorides and basic chlorides, which take up water in their formation and also clog the pores of the paper lining or paste, as well as incrust the surface of the zinc. In this way the available path for the flow of current is restricted and the resistance of the cell increased. As the cell is used, the MnO_2 is gradually reduced and the surface of the cathode moves inward. This makes the path between the zinc and the cathode a longer one, which also increases the resistance of the cell. The resistance of the cell increases slowly at first, but later increases very rapidly to large values. Fig. 10 shows the progressive changes in resistance of dry cells measured by an alternating-current bridge in the course of several tests. These curves are given for the 10-ohm test, a continuous discharge through 50 ohms and the light intermittent test.

Grouping of Cells

For most purposes dry cells are used in groups or batteries, the number of cells depending on the service required. It is desirable to arrange the grouping in such a way as to obtain the most economical service. Two factors are involved in arranging the cells; one

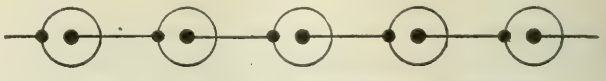

FIG. 11—CELLS CONNECTED IN SERIES

is the voltage requirement and the other the current requirement. When cells are connected in series—that is, when the positive pole of one cell is connected to the negative pole of the next and so on to the end of the row, Fig. 11—the voltage of the cells is additive. Two cells in series will give twice the voltage of one cell, and five cells will give five times the voltage of one, assuming that the cells, taken individually, are of the same voltage. If the voltage of one cell is E, the voltage of s cells in series is sE. When the cells are discharging, the voltage continually decreases. For this reason the number of cells required for a certain operation cannot be estimated on the basis of 1.5 volts per cell. The average working voltage of the dry cells may perhaps be taken as 1 volt per cell. If the voltage required is 4 volts, this means 4 cells in series. Another rule that is sometimes useful when the voltage requirement is not known is to connect cells in series, adding one at a time until the apparatus can be made to operate; then add an extra cell for each group of three or a fraction. This works out to give the same result in the example just given.

The rate at which the voltage will decrease when the cells are in use will vary with the current and duration of the discharge. A cell which will give 40 hours' service under normal conditions will not give 20 hours' service under twice the load. It may not give more than 10 hours. On the other hand, if the load is made very light, the service actually rendered may be small, because the deterioration of the cell becomes an important factor. As a guide to the proper use of the cell, information is given in Table VII.

The current drain on the cells can be relieved when

TABLE VII—CURRENT DRAINS FOR ECONOMICAL USE OF DRY CELLS

Duration of Daily Discharge, in Hours	Maximum Drain on Each Row of Cells In Series, In Amperes	Duration of Daily Discharge in Hours	Maximum Drain on Each Row of Cells In Series, In Amperes
16–24	0.02	½–[illegible]	0.75
8–16	0.04	¼– ½	1.50
4– 8	0.08	⅛– ¼	3.00
2– 4	0.16	Few moments	10 15
1– 2	0.32		

necessary by arranging the cells in parallel, or as it is also called "multiple." Cells are arranged in parallel by connecting the like poles together. Fig. 12 shows cells connected in parallel.

When more than three cells are involved in a series and parallel connection, there is a choice of arrangement. The cells may be arranged in several rows connected in series and then these rows connected in parallel (Fig. 13), or they may be arranged in parallel groups which are then put in series (Fig. 14).

Mathematically, the result is the same in either case. The voltage of the battery as shown in both figures

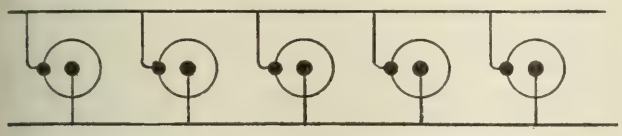

FIG. 12—CELLS CONNECTED IN PARALLEL

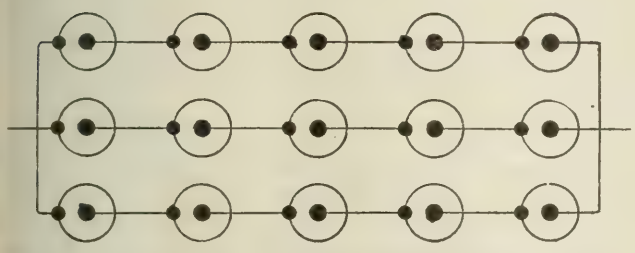

FIG. 13—PARALLEL OF SERIES-CONNECTED CELLS

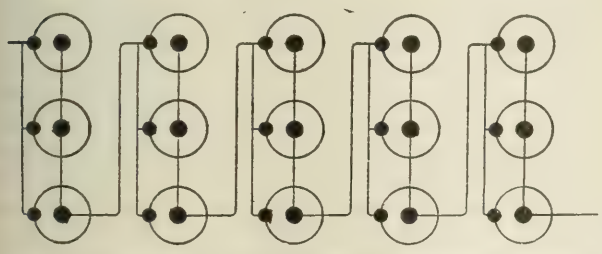

FIG. 14—SERIES OF PARALLEL-CONNECTED CELLS

is five times the voltage of a single cell, and the current furnished by any one cell is only one-third of the total current. The choice between the arrangements arises from the fact that one or more of the cells may fail before the others. For example, if any cell in each diagram should increase considerably in resistance, it would practically exclude one row of cells of the first diagram, Fig. 13, from service, reducing the battery to two rows. In the second case, Fig. 14, the battery would have four groups of three cells and one group of two cells, the effect of the bad cell being reduced to a minimum. In terms of resistance of the battery, the spoiling of the cell in the first diagram increases the resistance of the battery by 50 per cent, while in the second diagram it increases the resistance of the battery by only 10 per cent.

As the internal resistance of the dry cells increases, the current which they will deliver to any given circuit will decrease. If there are n cells, arranged s cells in series and p rows in parallel, the electromotive force of the battery will be sE, and if each cell has a resistance of b, the resistance of the battery will be $\frac{sb}{p}$. Applying Ohm's law to a circuit containing such a battery, equation 3 becomes:

$$I = \frac{sE}{R + \frac{sb}{p}} \qquad (9)$$

The maximum current that the battery can supply (when the external resistance is zero) is:

$$I = \frac{sE}{\frac{sb}{p}} = p\frac{E}{b} \qquad (10)$$

which is analogous to equation 4.

Whenever it may be necessary to use old cells for any purpose and the resistance of the cells has become of the same order of magnitude as the resistance of the external circuit, a choice arises between the series and parallel connections of the cells. If the resistance of the individual cells is less than the resistance external to the battery, more current can be forced through the circuit by putting the cells in series; but if the resistance of the individual cells is equal to the external resistance, the current is the same whether the cells are in series or parallel. If the resistance of the individual cell exceeds the resistance external to the battery, more current can be obtained by putting the cells in parallel.

Benzol Poisoning, Its Occurrence and Prevention*

By Charles F. Horan

Manager, Department of Hygiene and Safety, Hood Rubber Co., Watertown, Mass.

POISONING by industrial processes arise, for the most part, by the inhalation of the fumes. Because of its fat-dissolving qualities, benzol may also be absorbed through the unbroken skin, but it is doubtful if this mode of entry presents a serious hazard in industry. Lehman has shown that a man breathing a mixture of benzol and air actually absorbs 80 per cent of the benzol inhaled.

There seems to be some difference in the toxicity of pure and commercial benzol. The older reports indicated that commercial benzol was more dangerous than the pure, but the experience in the rubber industry would indicate that this conclusion was unfounded, there seeming to be a direct connection between the boiling points of the benzols and their ability to do harm; the compounds of lower boiling points appearing to be more dangerous than those of higher boiling points. This is probably due to the fact that the amount of vapor given off by the low-boiling point benzols is greater and thus a larger dose is breathed by employees exposed to the material. Considerable variations in individual susceptibility to benzol-poisoning exist, this being considered as the reason why the material has been used in some industries over a long period of time without serious symptoms having arisen.

Concerning this substance there is some division of opinion within the ranks of industrial hygienists as to

*Abstracted from paper read at the convention of the National Safety Council, Detroit, Mich., Aug. 30 to Sept. 1, 1922, inclusive.

its real dangers. There are those who consider the material with alarm and look upon all employees exposed to the vapors of benzol as being potential fatalities; there are others in industry who consider the vast amount of the material used and the relatively few cases of poisoning as evidence of lack of danger from benzol. These non-alarmists tell us that very few employees in industry are susceptible to benzol poisoning, and even in cases where little organized health protection is offered to employees using this material, cases of poisoning are rare and not usual happenings. They suggest to us that the statement "things are not what they seem" contains an element of truth; they remind us that industrial-accident statistics show the wheelbarrow to be more dangerous than the steam locomotive and the cement brush to be a greater fire hazard than the blowtorch.

In the central ground, and accepting the middle course, are those experienced industrial physicians and sanitarians who realize that the material is not nearly as dangerous nor as safe as some persons believe; that it can be used with relative safety only at the expense of the maintenance of certain precautionary measures.

Prior to 1914 several cases of benzol poisoning had been reported by Snelling. Three girls, aged from 14 to 16 years, were employed in a Maryland can factory in which the containers were sealed with a mixture of benzol, resin and rubber. Three other cases have since been reported from this factory. The most famous recorded cases of chronic poisoning were from a rubber tire factory in Sweden where nine young women, from 15 to 20 years of age, were taken ill with hemorrhages from the mouth, stomach, uterus and nose. Four of these girls died after an exposure to benzol lasting from 3 weeks to 3 months. In 1916 Dr. Alice Hamilton reported fourteeen new cases of sudden acute poisoning with seven deaths.

The reports of German factory inspectors for 1912 deal with three cases of poisoning, two of them being fatal. One man was employed in painting the interior of a barrel with benzol paint, another climbed into a washing machine in a dry-cleansing establishment and the third was employed in a distilling plant and forgot to turn on the cold water for the condensation. In 1918 British factory inspectors reported the case of a man overcome by benzol vapor while employed in a distillation plant. He was revived with oxygen and returned to work on the second day, only to be again overcome and die.

Recorded Cases of Poisoning

A number of cases of benzol poisoning have been recorded where employees were overcome while cleaning tanks in which benzol has been stored. In one case a benzol kettle had been empty for 24 hours, was washed out twice with steam and permitted to stand, filled with cold water, over night. As the workman went into the kettle a strong steam of air was blown in through a pipe. In spite of these precautions the workman was overcome, but was rescued. One of his fellow workmen who assisted with the rescue was overcome and died within 10 minutes.

One British case is recorded where a tank car was unloaded, washed with water, steamed out and then left, filled with water, for 20 hours; then washed twice with water, boiled for 12 hours and finally left for 10 days with a 16-in. manhole opened. A man who was then sent into the tank collapsed and, although he was revived in time, one of his rescuers died.

There have come to my personal attention, during the past 6 years, three fatal cases of poisoning to tire-builders in a pneumatic tire plant, one fatal and one acute case to female operatives in a thread-treatment room in a cord tire plant, one fatal case to a laborer engaged in digging a trench along a leaking tank of benzol, a fatal case to a foreman in a rubber-reclaiming department, three fatal cases in the coating room of an artificial leather factory, and about a dozen cases of less serious acute poisonings in a golfball department of a small rubber industry.

Condition of Temperature Is Important

So far as age is concerned, the very young, the old and the female seem to have particular susceptibility to the vapors of benzol. Debilitated conditions, organic diseases especially of the heart and kidneys, addiction to alcohol and excesses of all kinds materially increase susceptibility. Vigorous muscular individuals with rapid circulation and deep breathing are overcome more readily by benzol fumes because of the rapidity with which the vapors are absorbed.

As we would naturally expect, conditions of temperature and humidity effect susceptibility to benzol poisoning. Thus on hot, humid days, or in interiors where the air is hot and stagnant, poisonings are more likely to occur because of the greater volatility of the benzol under these conditions, and also, perhaps, because of retarded elimination, increased pulse rate, and hence the greater flow of blood through the lungs under these circumstances.

The symptoms of poisoning naturally vary according to the length of exposure, individual susceptibility and the amount of benzol absorbed. As Dr. Reifschneider will probably tell us of the symptoms of the poisoning in both the acute and chronic state, I shall pass along to the prevention of the poisoning.

From the standpoint of those engaged in safety work, the methods of prevention of benzol poisoning are of much more importance than any other phase of this problem. The first step in the prevention of the poisoning is to be found in the physical examination of each applicant for work and periodic re-examination of those exposed to the hazards of benzol. Persons suffering from organic diseases, especially of the heart and kidneys (which diseases tend to retard elimination), should not be placed on occupations where the exposure to benzol constitutes an occupational liability. Physical examinations should include a differential blood examination, an estimation of hæmoglobin and a determination of the coagulating time of the blood. Experience indicates that re-examination every 4 weeks is not too often.

Follow Up all Suspected Cases

All cases of absence from work should be investigated if the absence extends beyond 24 hours. In event of the employee being away from his occupation because of sickness, he should be visited by a physician familiar with the early symptoms of benzol poisoning. Note should be kept of the state of health of the workers, the results of periodic physical examinations, the duration of symptoms and the treatment of illnesses that occur. Care should be taken to have the records complete and entries such as "coagulating time, normal," should be discouraged. Employees should be encouraged

to use the factory dispensary in event of illness and it scarcely requires to be said that medical aid should be within easy reach.

We have now come to the subject of the education of the worker. In the prevention of occupational diseases the co-operation of the employee is indispensable and is the most important condition of an effective defence. The best regulations and preventive measures are worthless if the worker does not observe them. The employee should be advised as to the dangers incidental to his employment and he should be acquainted with the symptoms which demand early medical attention; he should be taught the aims of the management with reference to the prevention of industrial poisoning.

Fumes Must Be Driven Off at Bottom

Dr. Hamilton reports a procedure at the Gary plant of the United States Steel Corporation in connection with safety in cleaning apparatus which has been used in the manufacture or storage of benzol: After washing out the empty tank and steaming it a cage of white mice is lowered into the tank. If the mice are overcome by the gas the flooding and steaming are repeated until the mice show no effects of the benzol. The use of a portable electric-driven gasblower to exhaust air through the drain pipes of tanks has been of much value. Because of the benzol vapor being heavier than air, it is necessary to exhaust at the bottom of the tanks, and drain pipes are conveniently located for this purpose.

Where benzol is used industrially as a solvent, it has been found necessary to install general room ventilation, rather than hope to confine the ventilation to a small number of exhaust hoods. In a scheme of general room ventilation it is well again to remember that benzol vapor is heavier than air and should be exhausted at the floor level. Our experience illustrates that an air change of thirty times an hour is desirable and that the flow of air toward the floor should be not less than 6 ft. per minute. The British standards in rooms where airplane wings are "doped" concurs with our ventilation of thirty changes an hour.

In conclusion, permit me to say that with an efficient method of physical examinations, with regular reexaminations; the changing of an employee's occupation as quickly as he shows either an abnormal reduction in number of blood cells or an unusual increase in coagulating time; together with adequate ventilation, benzol not only can, but is, being used without danger. If managements and employees are willing—and most of them are—to maintain reasonable safety requirements, benzol will continue to be a cheap and powerful solvent and need not be the cause of needless sickness or death to employees in industry.

Bricks From Dolomite

At the Columbus, Ohio, ceramic experiment station, the Bureau of Mines has made standard sized bricks from calcined dolomite and from raw dolomite, using 10 per cent of the flux Fe_2O_3, Al_2O_3, SiO_2. Calcined dolomite was found undesirable for making into bricks, as the mud slakes so rapidly, and all samples cracked badly on account of enormous shrinkage during drying and burning. Raw dolomite, together with 10 per cent flux, gives excellent promise. The bricks so burned to 1,450 deg. C. were sound, of high density and have not yet shown signs of slaking when subjected to the boiling test.

Grinding Cracks

A RATHER mysterious defect—almost always charged against incorrect heat-treatment—often appears as a close network of fine cracks covering a hardened article after finish grinding, causing large losses in rejections. A practiced eye can see faint "ghosts" of such markings on an apparently perfect surface. Pickling in 10 per cent sulphuric acid brings out the defect very plainly, developing the latent cracks rapidly (Fig. 1).

Messrs. Guillet, Galibourg and Beuret have investigated this matter and show how they were able to prevent the trouble, in *Revue de Métallurgie*, 1921, p. 213. They call attention to the fact that it is a quite different phenomenon to the exfoliation or flaking away of considerable areas of carbonized surfaces. Giolitti has investigated this, and ascribes it to sudden variations in carbon content in successive layers of the cemented zone. Messrs. Hanson and Hurst[1] think grinding cracks are due to segregation of free cementite in a thick network; when this was suppressed, rejections in a hardened ground 2½ per cent nickel steel were reduced to one-tenth their former number. Impurities in the steel also are thought to have some influence; furthermore, local heating during finishing must be avoided. Other authors have called attention to the great similarity which exists in the appearance of grinding cracks to the fine surface cracks on a wheel-burnt rail (shown by J. E. Howard[2] to be due to rapid heating under a slipping engine driver and sudden chilling by conduction) to the cracks appearing on steel mill rolls and to the cracks in the bore of large caliber guns.

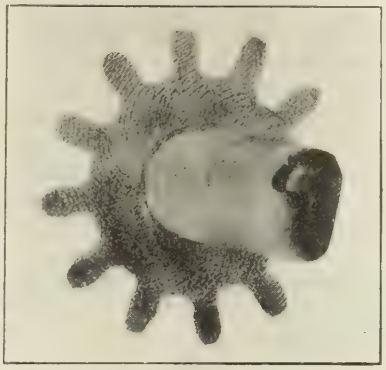

FIG. 1—GRINDING CRACKS DEVELOPED BY PICKLING THE SURFACE OF A HARDENED PINION

Many possible factors during heat-treatment or grinding might be responsible for the defect, but on account of the similarity with other imperfections found after close study to be due to transient overheating, the French authors decided to study the grinding process. Furthermore, a piece, uniformly carbonized and hardened, will show indications of cracking in certain places where the grinding conditions varied slightly. For instance, a closer network of cracks always occurs at the ends, where the wheel begins its work. Plane surfaces also seem more susceptible to the fault than cylinders. It is also very significant that whereas the specimens are file hard before grinding, those which develop cracks may easily be touched by the file after grinding. This alone would seem to indicate that they have lost some of the surface properties acquired by case-hardening, and this could best be explained by a slight heating during grinding.

To test these suppositions, a cylinder of low-carbon steel was carbonized to about 1 mm. depth over half its length only. The entire specimen was then quenched

[2] Report to Interstate Commerce Commission on accident at Glenwood, W. Va. Abstracted in *Chem. & Met. Eng.*, May 11, 1921.

TABLE I—EXPERIMENTS ON PINIONS

Anneal	Speed of Part, r.p.m.	Result
30 min. at 150 deg.	500	No cracks on flat or shaft
30 min. at 150 deg.	120	Deep cracks on all surfaces
None	500	No cracks on flat or shaft
None	120	Deep cracks on all surfaces
None	120 (new wheel)	Deep cracks on all surfaces
None	120 (dirty wheel)	Deep cracks on all surfaces
None	440 (dirty wheel)	No cracks on flat or shaft

for maximum hardness, and ground from end to end. After pickling, cracks appeared on the carbonized end only. That part, on being broken, showed the usual coarse crystalline core, the fine crystalline muff, and, in addition, a very thin surface layer, colored bluish in tint. A micrograph of the surface layer where it was not carbonized (Fig. 2) clearly shows the effect of surface heating by the incipient decomposition of martensite areas into troostite.

Acting on the idea that superficial heating during grinding is responsible for the surface cracks under investigation, it was found possible to avoid them entirely by speeding up the rotation of the cylinder as high as possible. It is easy to see that this reduces not only the time the wheel is in contact (and the steel is being heated) but the time elapsing before the hot metal is cooled by being struck by the cooling fluid.

A number of experiments were performed, of which the following are typical:

Fifty-two bars of medium carbon crucible steel (made of blister bar) were selected. Bars 1 to 28 were carbonized 0.5 mm. and the others 1.0 mm. deep. All bars were quenched from 800 to 825 deg. C. Bars 1 to 15 and 29 to 40 were then tempered 30 minutes at 150 deg. C. Finally each lot was divided, one part being ground at 120 r.p.m. and the others at 500 r.p.m. The striking result followed that *all* bars ground when revolving at 120 r.p.m. developed quenching cracks, and *none* appeared in those ground when revolving at 500 r.p.m., notwithstanding the large variations in previous heat-treatment.

A number of hardened pinions were then studied, like those shown in Fig. 1, and which had always given

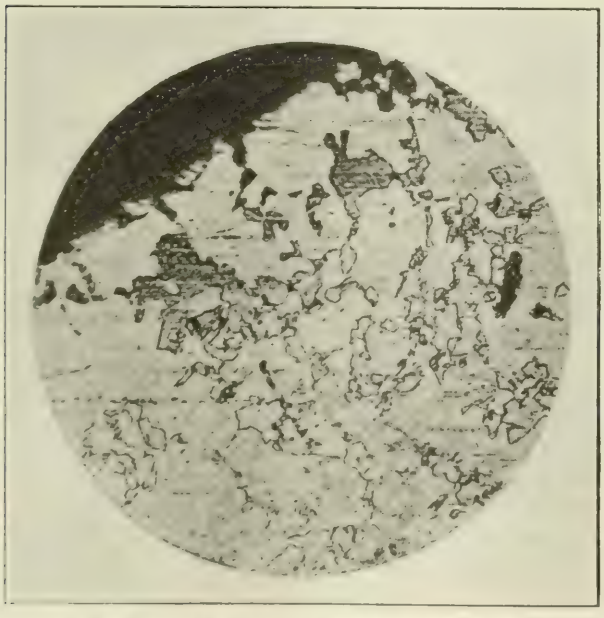

FIG. 2—DECOMPOSITION OF MARTENSITE NEAR SURFACE OF LOW-CARBON CYLINDER, QUENCHED AND GROUND

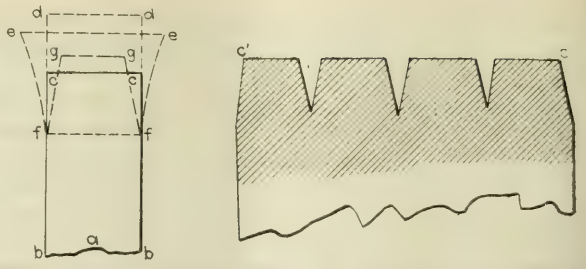

FIGS. 3 and 4—MECHANISM OF SURFACE CRACKING CAUSED BY TRANSIENT OVERHEATING

great trouble by cracking both on pinion and shaft. Table I contains the results. If the speed of the piece being ground is high enough, it seems that the condition of the grinding wheel is also only a minor factor.

Finally, it was found possible to develop the same kind of cracks at will, and without grinding, if a little molten copper be poured on a flat hardened surface, and then immediately drenched with a strong water jet.

The mechanism of the action has been explained by the late Prof. D. Tchernoff, in a paper entitled "On the Erosion of Steel Guns by Powder Gases."[3] While the tube is filled with the hot compressed gases resulting from an explosion of powder, the extreme surface of the metal is very highly heated, but almost instantly cooled after the escape of the gas by the conduction of the heat back into the underlying metal. If an elementary prism of metal supposed to be free of surroundings is heated on the end surface *cc* (Fig. 3) in the described manner, it would expand to a shape like *bfeefb*. On the other hand, if it were held in sidewise constraint, as it would be in a gun tube, the shape assumed during the transient heating would be *bddb*. It is apparent that if the heating has been high enough, the surface layers will be overstrained in compression and the metal at the surface will be plastically deformed. During cooling, therefore, the surface *dd* will contract more than enough to relieve the induced compressive stress and a state of tension will exist in the cold surface, now slightly higher than the original *cc*, which causes ruptures and radial cracks. The net result of this cycle of operations is shown in Fig. 4.

Italian Manufacturers of Tartaric Acid Merge

Commercial Attaché H. C. MacLean reports from Rome the announcement of a merger that has been effected under the auspices of the Credito Italiano between four important Italian companies manufacturing and trading in tartaric acid. The Societa Anonima L'Appula, whose main office is at Bari, has increased its capital to 25,000,000 lire, and has absorbed the Fabbrica Lombarda di Acido Tartarico, the Societa Anonima Industria Acido Tartarico and the Societa Italiana per i Derivati delle Cellulosa. The three latter companies have already ratified the conditions under which the merger will be effected.

Welding Cast Iron With Thermit

It is recommended to preheat cast-iron parts to be welded with Thermit no higher than a dull red heat. This is sufficient for perfect fusion with the hot metal being added. It has also been found that the total contraction of both cast iron and weld metal is sufficiently close so that there is little danger of hairline cracks perpendicular to the plane of break.

Synopsis of Recent Chemical & Metallurgical Literature

Peanut Oil Industry as a Source of Byproducts

The commercial production of peanut oil, which has developed rapidly since 1915, has resulted in the appearance on the market of large quantities of byproducts that are used principally as feeds for livestock. One reason for the phenomenal growth of the industry is that the peanut can take the place of cotton as a cash crop in regions where the weevil has made the growing of the fiber crop unprofitable. The peanut has been a boon to the oil millers as well as to the planters, for the oil is produced in the same mills that are used for extracting cottonseed oil.

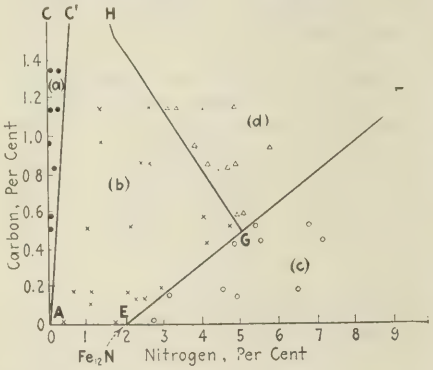
The processes of making peanut oil and the byproducts are described in Department Bulletin 1096, "Byproducts From Crushing Peanuts," by J. B. Reed, of the Bureau of Chemistry, just issued by the United States Department of Agriculture. The principal products other than the oil are peanut-oil cake, which is defined as the residue after extraction of part of the oil by pressure or solvents from peanut kernels, peanut-oil meal, which is the ground peanut-oil cake, and unhulled peanut-oil feed, which is the ground residue obtained after extraction of part of the oil from whole peanuts. The ingredients of the last-named feed must be designated as "peanut meal and hulls." Theoretically peanut-oil meal, which is made from the kernels after a part of the oil has been extracted, should contain no hulls, but because commercial methods cannot remove all the hulls, it is necessary to permit a small amount of hulls in the meal in order that the definition may be practical.

The bulletin contains detailed information and analysis of the different kinds of feeds and formulas for determining the percentage of hulls. Much of the information is technical and of interest only to feed analysts and officials having to do with the enforcement of feed laws.

Nitrogen in Steel

A series of steels and ore sample of cast iron were nitrogenized by Kiyoshi Kido[1] to various degrees by beating pulverized samples in a current of dry NH_3. They were then compressed in a small copper tube and magnetization-temperature curves obtained upon heating. One heating only was possible, since the alloy becomes unstable at temperatures higher than 700 deg. C.

Four magnetic change points were noted in addition to the well-known A_0 of cementite at 215 deg. C., and A_2 of ferrite at 750 deg. C.—viz., at 250, 350, 470 and 620 deg. C., respectively. Researches of Tschischewski[2] have given evidence of the existence of two nitrides $Fe_{12}N$ and Fe_2N. Low-carbon iron containing about 2 per cent N shows its most important magnetic change at 470 deg. C. This has been ascribed to $Fe_{12}N$. As the amount of N in low-carbon steel rises still further, another magnetic change at 250 deg. C. increases in importance—it is thought to be due to Fe_2N. The two other changes are ascribed to unknown "double carbides." The accompanying diagram shows the constitution of various alloys as determined in this manner.



Low-Pressure Absorption of Gasoline From Natural Gas

Many recent and surprising developments in low-pressure absorption practice for the recovery of gasoline from natural gas and the growing reluctance of certain purchasers of refined or partly refined products to take blended gasoline convinced the petroleum division of the Bureau of Mines that a detailed description of a large plant treating rich casinghead gas at low pressure would be of aid to the industry. Although the product of the plant described in this paper is blended, it has such a vapor pressure that blending is not necessary. Technical paper 263, by W. P. Dykema and A. A. Chenoweth, is entitled "Design and Operation of a Low-Pressure Absorption Plant."

This report deals with the construction, the operating methods, the many changes necessitated and the difficulties encountered in the recovery of gasoline from a rich casinghead natural gas by absorption at low pressure. The results of heat generated in the absorption towers are particularly noted, and a possible means of overcoming the undesirable effect of such heat is proposed.

The plant referred to was installed during the winter of 1916-17 in the Cushing oil field in Oklahoma. Far from a perfect result has been achieved in the plant; nevertheless a more or less detailed statement of the main features of the plant and its operation will probably interest, and, it is hoped, aid those persons operating or designing absorption plants to treat similar gases. The plant was designed and is operated as a low-pressure installation, the specification for the absorption tower calling for steel work to sustain a maximum pressure of 15 lb. per sq.in. The gas used comes from approximately thirty wells, drilled to the Bartlesville sand and producing oil and gas of good quality.

Part I of this paper includes a detailed outline of the plant and its regular operation with records of temperatures, pressures, production and changes in equipment. Part II considers data on the latent heat of absorbed gases and a proposed means of overcoming the increase in temperature of the oil as it circulates through the towers.

The paper may be obtained by applying to the United States Bureau of Mines, Washington, D. C.

The Quality of Motor Gasoline

For several years the Bureau of Mines has conducted surveys to determine the changes in motor gasoline being sold throughout the United States. The results of the sixth semi-annual survey are presented in the August *Reports of Investigations* (Serial No. 2,388) by A. D. Bauer, assistant petroleum chemist, and N. F. Le Jeune, assistant chemist.

The present survey shows that for the districts in which samples were collected the average gasoline is becoming more volatile instead of less so, as is sometimes supposed. This year's gasoline is much more volatile than that sold 2 years ago, and it has a somewhat better distillation range than last summer's samples. A comparison of the average figures for several years shows that motor gasoline is also becoming more uniform in character. The large seasonal change is disappearing, but "winter gasoline" still has a lower initial boiling point than "summer gasoline." This difference in volatility is made intentionally to facilitate starting the motor in cold weather. The end point shown in the present survey is slightly lower either

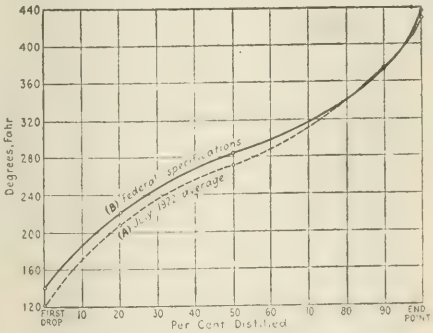


Fig. 1—Distillation curves for (*A*) Average quality of gasoline sold in July, 1922, and (*B*) gasoline meeting federal specifications.

[1] *Science Reports*, Imperial Tohoku University, vol. 10, p. 471.

[2] *J. Iron & Steel Inst.*, 1915. II.

than that of last winter or of the summer of 1921.

The average of the entire country considered as a whole does not show much change from a year ago, but samples from individual cities show some distinct changes. The average figures for Denver show that the initial point is lowered 15 deg. F., the 90 per cent point 14 deg. F. and the end point 21 deg. F., whereas the 20 and 50 per cent points increased 11 and 13 deg. F. respectively. This change may be due to the fact that Denver receives gasoline from one group of refineries at one period and from another group at other times. Of 132 samples collected in the present survey, ten failed to meet federal specifications (adopted Nov. 25, 1919) as regards the initial boiling point of 140 deg. F., and 61 samples failed at the 90 per cent point (374 deg. F.).

The city of Bartlesville, Okla., is included in the present survey, as it is in the center of the mid-continent field. The actual specific gravity at 60 deg. F., the corresponding A.P.I. gravity, the initial boiling point or first drop, the 20, 50 and 90 per cent points, the end point and average boiling point, and the percentage recovered in the receiver were determined and tabulated for each sample.

A distillation curve representing the average figures for the July, 1922, survey, and a curve showing motor gasoline meeting federal specifications are to be found in Fig. 1.

Brittleness of Tin Foil

Some interesting investigations on aluminum containing tin have been carried out by E. Heyn and E. Wetzel of the Kaiser Wilhelm Institut für Metallforschung at Neubabelsberg and have been published in the *Proceedings* of this Institute, and summarized in *The Engineer* for Aug. 18, 1922. The investigations arose from the attempts to elucidate the origin of the brittleness of certain tin foil, which when freshly rolled was as soft and pliable as the average material, but which after a few days became through and through brittle. The origin has been traced to a small amount of aluminum contained in the tin. Even 0.25 per cent of aluminum is sufficient to make the tin completely brittle in a short time, so that the foil breaks up on the slightest bending stress. The effect is probably due to great difference in electrolytic potential between tin and aluminum, which under moist atmospheric conditions results in the gradual conversion of the aluminum to aluminum oxide. The splitting process always commences at the surface and makes its way down into the center of the material. Tin which, owing to the above cause, has been rendered useless can be regenerated and completely freed from aluminum by melting, when the alumina remains as a gray residue. The addition of lead to the tin does not retard the advent of the brittleness, but the addition of 2 or more per cent of copper is advantageous.

Book Reviews

FLUIDITY AND PLASTICITY. By *Eugene C. Bingham.* 440 pp., no illustrations. New York: McGraw-Hill Book Co., Inc. Price, $4.

The author has brought together and attempted to co-ordinate the vast amount of information on the flow of materials under shearing stress which has hitherto been scattered through the journals; and the resulting volume is valuable and welcome. The subject matter falls into two categories—namely, instruments and methods for measuring rates of flow, together with the necessary mathematical theory; and the relations of the results of such measurements to the physical and chemical properties of the various fluid or semi-fluid materials in question.

It is in the second of these subjects that the author, as a chemist, seems to be most interested and most at home, and this part of his work is therefore the more satisfactory. A great number of interesting facts and relationships are described and such theory as is available or as the author has been able to devise for himself is used to systematize the material. The theoretical reasoning is sometimes not very convincing, and the author's enthusiasm over a pretty idea is apt to make him forget that what was a hypothesis on one page does not become a certainty merely by turning over a few pages and writing it down again. Furthermore, it is often quite impossible to tell, without referring to the original papers, how much of the argument is the author's and given on his own responsibility and how much is quotation. For while an admirable feature of the book is its very extensive bibliography and author index, the references given in the text are usually so vague and indefinite that one does not know just where to look or whether it is worth while to look at all.

For some readers these would be serious faults and in fact to get the best out of the book the reader should be sufficiently mature to have a good deal of critical judgment and be well past the stage of accepting things because they are written down as if with authority. But if the book is regarded in its proper light, not as a treatise or handbook but as a guide to the study of the relations or fluidity and plasticity to other properties, it will be suggestive and stimulating as well as extremely useful.

Since fluidity and plasticity are purely mechanical properties it is not to be wondered at that the discussion and theoretical treatment of instruments and methods of measurement are less satisfactory than the physico-chemical part of the work. The author does not exhibit the precision of thought necessary to the satisfactory exposition of this part of his subject matter. He is often careless or inconsistent about definitions, notation and the use of words. For example, shearing stress, which is the most fundamental and important of all the quantities with which he has to deal, is sometimes called shearing "force," but almost always "shear," which means something quite different.

As regards methods, the author confines his attention almost exclusively to the capillary type viscocimeter with which his own very extensive experimental work has been done. His discussion of the theory of this instrument is passable. He makes the common mistake of supposing that the entrance correction treated by Boussinesq is a part of the kinetic energy correction, but this makes no difference in the practical application of the equations. When he comes to his own particular specialty, the flow of "plastic" materials through capillary tubes, his disregard of logical accuracy is more injurious to his result; and his most trusted formula, equation 89, p. 225, is mathematically incompatible with the hypothesis from which it is supposed to follow (equation 73, p. 217). The theoretical treatment is defective and unsatisfactory in several other respects, as well.

But after mentioning some of the more striking faults of the book and hinting that the author's English is sometimes decidedly queer, the reviewer gladly returns to the earlier point of view, that the merits of the book far outweigh its defects. It might have been better done, but it is well worth having as it is, and the chemical public should be grateful for this monument to the author's industry.

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

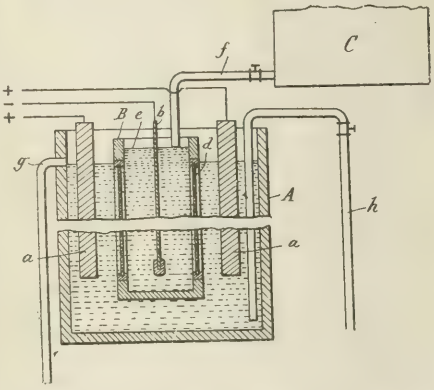
Aluminum Plating—Anselmo Ortiz, of Bayonne, N. J., notes that previous attempts to produce an aluminum coating on iron or steel articles by the hot-dipping process have resulted in a very rough surface (due to corrosion at very high temperature), or a coating consisting not of pure aluminum but an aluminum-iron alloy (when working at moderate temperatures). He proposes first to clean the steel article by pickling in 50 per cent ammonium citrate, washed and dried. Then it may be covered with a flux—a mixture of KCl, NaCl and $ZnCl_2$ melting below 600 deg. C. The aluminum is melted under a reducing atmosphere, held at 650 deg. C. or somewhat higher, and skimmed. The iron article is dipped into the bath at a rate just great enough so that the meniscus, where the aluminum wets the iron, is neither destroyed nor inverted. Its presence proves the wetting of the iron by the

aluminum, and insures that oxides or dirt at the junction will be removed from the contact. Under these conditions the steel will join to a smooth aluminum coating through a transition alloyed zone. (1,409,017; assigned to General Electric Co. March 7, 1922.)

Projectile Manufacture—John L. Cox recommends the following schedule of heat-treatments for armor-piercing shell made of nickel-chromium steel: After forging, cool quickly, at least through the critical range. Refining is done by reheating somewhat above Ac_3 and cooling rapidly to below the transformation. Grain refining preparatory to machining is done by reheating above Ac_3, cooling quickly to below Ar_1, reheating to just below Ac_1 and then cooling slowly. After rough machining, further grain refinement is done. Depending upon the caliber, it is reheated once or twice to 130 deg. C. above Ac_3, each time cooling rapidly through the transformation. Next a similar treatment is given 75 deg. C. above Ac_3. Maximum toughness is then acquired by quenching in warm water from 75 deg. C. below Ac_1, removing the projectile while fairly warm, to prevent cracking. Finish machining can then be done. Final hardening is done thus: First preheat the whole to just below Ac_1; then heat the forward part above Ac_3 by immersing the head gradually in a lead bath. It is then quenched by water jets to 120 deg. C. Immediately it is drawn for several hours in a bath of oil at 100 to 200 deg. C., depending upon the caliber and the composition. After cleaning, the base of the projectile is gradually immersed in molten lead, and drawn to about 70 deg. C. below Ac_1, then quenched in a water spray operating on the base only, so that a band of hot metal below the hardened point is untouched by the water. Then invert the projectile in a shallow bath of water, to keep the point cool. (1,407,254 and 255. Feb. 21, 1922.)

Alumina From Impure Ores—R. S. Sherwin of East St. Louis, Ill., claims that pure alumina may be recovered from low-grade bauxite, clays or aluminum-bearing residues from present processes as follows: Grind the raw material with enough lime to form $CaO.SiO_2$ with the contained silica and about one-half as much soda ash as necessary to make $Na_2O.Al_2O_3$ with the contained silica. The mixture is then sintered, and the clinker ground. Leaching with sodium hydrate solution (containing 4 molecules NaOH for each molecule of Al_2O_3) then removes the soluble aluminate, and leaves behind most of the insoluble lime silicate, if the temperature is maintained between 180 and 200 deg. F. Some silica also goes into solution, and it can be removed by digesting 2 hours in an autoclave at about 290 deg. F. Complete removal (requiring a longer time) is not required unless the Al_2O_3 is to be removed from solution by CO_2 gas. A somewhat more impure solution is suitable for the Bayer process (which precipitates Al_2O_3 by inoculating the solution with freshly precipitated $Al_2(OH)_3$ and agitating about 3 days). Alumina is then filtered off, enough of the solution evaporated to dryness to provide sodium for subsequent furnace charges, and the remainder used for another digestion. (1,422,004; assigned to the Aluminum Co. of America. July 4, 1922.)

Electrolytic Nickel—N. V. Hybinette, of Christiania, Norway, patents an improvement in his process for recovery of nickel from copper-nickel anodes (805,969; Nov. 28, 1905). As in the earlier patent, the cathode compartment *B* (see fig.) is supplied with fresh, pure nickel sulphate solution. Instead of maintaining this strictly neutral, a solution at 55 deg. C. containing 50 grams nickel sulphate and 2 grams H_2SO_4 per liter is introduced. The diaphragm *d* is not so porous as formerly, but is made of heavy cotton cloth, which permits the free SO_4 ions to migrate outward very rapidly; thus the actual conditions within compartment *B* are substantially neutral.



Maintaining a hydrostatic head of about an inch causes sufficient outward flow of liquid to prevent any copper entering the cathode compartment. Overflow electrolyte is withdrawn through *g*, and somewhat more impure liquid through *h*. This circulating liquid is purified of copper by cementation on nickel, of iron by reaction with nickel oxide, and the acid concentration is rebuilt by depositing nickel in a similar cell having insoluble anodes. Copper-nickel anodes made in an electric furnace have been found to be superior to the blast-furnace product, being denser and lower in iron and sulphur. (1,395,827. Nov. 1, 1921.)

Furnace Refining of Copper—Oliver C. Martin, of Richmond Hill, N. Y., patents an arrangement for refining copper. He utilizes a reverberatory furnace for continuous melting of cathodes or pigs of impure metal. These are side-charged, to protect the furnace walls and without opening the furnace, and the molten metal is drained out the end of the furnace as it is formed. Thence it is laundered into one of three furnaces built much after the style of a Pierce-Smith converter. These three are mounted symmetrically on a large turntable; while one is filling the second is poling and the third pouring into a casting machine of approved type. All furnaces are connected to waste-heat boilers. By means of such continuous operations, many economies may be effected. (1,400,892; assigned to Nichols Copper Co. Dec. 20, 1921.)

Manufacture of High-Silicon Sheets—Andrew Pinkerton, of Ben Avon, Pa., proposes to make high-silicon sheets (for electrical apparatus) of uniform thickness and having surfaces which will not peel and crack when the sheets are bent or sheared as follows: After the cold-rolling operation the sheets are pickled, washed and annealed. Pickling is necessary to remove the scale, but if this operation is done on annealed sheets, it requires much time and acid, and results in a very rough surface. (1,396,052; assigned to American Sheet & Tin Plate Co. Nov. 8, 1921.)

Regenerator for Furnaces Fired With Cold Dust—Paul Kühn, of Dortmund, Germany, proposes to avoid slagging in the checkerwork by coal ash as follows: Dusty gas leaves the furnace and passes through downtake and slag pocket in the usual way. The first section of the regenerator is built with sloping floor (and preferably on a movable sole plate so it can be quickly replaced). In action the dust is supposed to collect in these sloping flues and drip back into the slag pocket, from which the liquid is tapped periodically. The second portion of the regenerator is built at an angle with the first and has horizontal checkers from which, the inventor states, any dust which collects may be removed in powdered or granular condition. (1,421,259. June 27, 1922.)

Dichlorethylene—Felix Kaufler, of Munich, Germany, has patented the principle of converting tetrachlorethane to dichlorethylene at atmospheric pressure by passing it in gaseous form over a metallic catalyst with steam. It is said that the yield of crude dichlorethylene amounts to 88 per cent of the theoretical maximum. On fractional distillation, this crude product gives about 90 per cent of dichlorethylene which boils at 48 to 60 deg. C. The residue is unchanged tetrachlorethane. The process is assigned to the firm Dr. Alexander Wacker Gesellschaft für Electrochemische Industrie, Munich. (1,419,969. June 20, 1922.)

Black Powder—The use of artificial graphite from old electrodes, crucibles, etc., for glazing black powder is covered in a disclosure made by John R. Mardick, of New York City, and assigned to the Acheson Graphite Co., of Niagara Falls. It is claimed that when such waste graphite products are ground finely and used instead of natural graphite for glazing black powder grains it gives a more uniform covering and improved moisture resisting qualities, as well as increased sensitiveness, uniform progression of fire, and uniform velocity of explosion. (1,415,889. May 16, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Formaldehyde—Formaldehyde is produced by passing carbon monoxide, hydrogen and water vapor over a contact substance at a temperature of 240 to 350 deg. C. Suitable contact substances are unburnt porcelain, pumice, asbestos, coke or charcoal, preferably coated with a metallic deposit of copper, nickel, etc. (Br. Pat. 179,951. A. Heinemann, Berlin. July 5, 1922.)

Rustproof Steel—A coating composition to be applied to steel and iron surfaces to prevent rust and to convert existing rust into an inert form comprises an oxy-acid of phosphorus, an oxide of hydrate of chromium and a solvent of these, with or without oxides, hydrates or chromates of manganese, lead or nickel. According to one example, a mixture of lead oxide and orthophosphoric acid is dissolved in a mixture of wood spirit, acetone, ethyl alcohol and methylated spirits, and a mixture of chromium oxide and phosphorus acid is added thereto. According to another example, chromic hydroxide is digested in 24 hours with boiled linseed oil or other drying oil, with or without heating, orthophosphoric acid is then added and the mixture is agitated. Pigments possessing rust-reducing properties may be added. The composition after drying may be covered with a coating of paint, varnish, enamel or the like. (Br. Pat. 179,811. G. H. Howe, Birmingham, England. July 5, 1922.)

Paper Pulp—In the preparation of paper pulp from papyrus, the material is first boiled, steeped or retted, and then subjected to mechanical pressing with simultaneous washing to remove the pith, and then beaten to pulp. The removal of the pith may be effected during the pulping, the mechanical pressing being omitted. A preliminary grading may be effected by splitting off the bark either before or after the boiling or steeping. The waste products, mainly pith, are in wet condition subjected to great pressure, and formed into briquets, cakes, etc., in quantity sufficient to supply the entire fuel for the requirements of the process. (Br. Pat. 180,097; H. Steinhilber, Berlin. July 12, 1922.)

Aluminum—Aluminum is obtained by electrolysis of fused alumina mixed with barium oxide or metallic barium. Cryolite and fluorite may be added as fluxes. In an example, the alumina is first fused and barium oxide mixed with 10 per cent of powdered or fine-grained aluminum is then added, the addition being one-sixth of the weight of alumina. A little fluorspar may also be added. The bath is raised to 1,200 deg. C. by the oxidation of the aluminum and the reduction of the alumina by electrolysis then proceeds. In subsequent operations alumina is added and after fusion, aluminum mixed with a little alumina is also added, no further addition of barium oxide being necessary. Fluxing material is added to replace that volatilized. With a furnace containing 30 kg. of alumina using 20,000 amp. at a pressure of 7 volts, at least two operations per hour may be effected, each yielding 15 kg. of aluminum. (Br. Pat. 180,326, not yet accepted; M. Blasi, Barcelona, July 12, 1922.)

Extracting Vegetable Oils—Oils and fats are extracted from oleaginous vegetable matter by subjecting it, with or without previous preparation such as grinding, to the action of just sufficient solvent to soak it and then extracting the solvent and oil together under low pressure, say 1 to 10 kg. per sq.cm.

FIG.1.

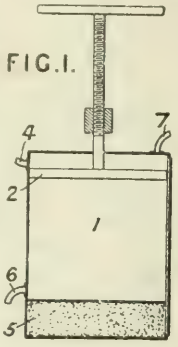


FIG.2.

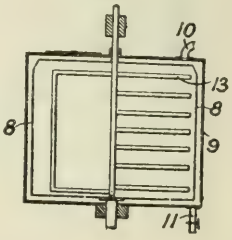

The temperature of operation is kept below that of volatilization of the solvent, for example, 30 to 75 deg. C. In one form of apparatus, Fig. 1, a vessel 1, provided with a plunger 2, is used. The solvent is introduced by an inlet 4, and the oil and solvent run off through an outlet 6. The residual cake 5 may be heated to drive the solvent off through a pipe 7. Another form of apparatus, Fig. 2, consists of a rotary extractor 8, provided with an oppositely rotating agitator 13, and inclosed in a chamber 9 having an inlet 10 and an outlet 11. After soaking for, say, 10 to 20 minutes, the vegetable matter is subjected to rotation at a speed corresponding with the low pressure desired. (Br. Pat. 179,931; not yet accepted. Cellulose et Papiers Soc. de Recherches et d'Aplications, Paris. July 5, 1922.)

Formaldehyde—A gaseous mixture of carbon monoxide and hydrogen—for example, suction or water gas—is forced under pressure through a catalytic mass consisting of a hydrogen-activating catalyst such as nickel or cobalt and a hydrated metal oxide such as alumina or rare earths, the activity of the mass being maintained either by the introduction of steam into the gaseous mixture or by periodic treatment with steam. Formaldehyde is removed from the product by scrubbing with water; the residual gas, which contains methane and hydrogen, is of value as an illuminating gas. (Br. Pat. 180,016; E. J. Lush, London. July 12, 1922.)

Alcohol—Ethylene is removed from industrial gases by passing them through warm concentrated sulphuric acid containing as catalytic material a lower oxide or salt of a metal possessing more than one valency—namely, iron, cobalt, nickel, cerium, manganese, chromium, copper, lead, mercury, titanium or tin; the resulting ethyl hydrogen sulphate is then hydrolyzed in the known manner to produce alcohol or ether. Ferrous sulphate, cuprous chloride, copper sub-oxide and cuprous sulphate are specifically mentioned as catalysts; higher oxides and salts of the metals may be employed, provided that a reducing substance be present. The catalysts are insoluble in the sulphuric acid and are recovered from the product for re-use. The industrial gases referred to comprise natural gas, coke-oven gas, illuminating gas, gases obtained by cracking oils, schist gases and synthetic ethylenes. Preferably they are first freed from benzene, ammonia, water, sulphur compounds, acetylene hydrocarbons and ethylene homologs. An example is given of the recovery of ethylene from illuminating gas by passing the purified gas through a column containing pumice in which circulates sulphuric acid of 66 deg. Bé. containing 4 per cent copper sub-oxide and maintained at a temperature of 35 to 40 deg. C. (Br. Pat. 180,988; not yet accepted; A. A. L. J. Damiens, Seine, France. July 26, 1922.)

Destructive Distillation.—The destructive distillation of fuel, more particularly peat, is effected in ovens which are connected and operated after the manner of a continuous kiln. The apparatus comprises a number of chambers arranged in "ring" formation and heated by external flues in which are vertical partitions having openings alternately at top and bottom. In operation, one section of the chambers will be cooling off after firing, the cooling being effected by air which is passed through the flues on its way to the adjacent firing section. From this section the products of combustion are passed through the flues of other chambers in which the charges receive a preliminary heating. The operation is so controlled that a charge is heated up to its maximum temperature in about four days. (Br. Pat. 180,689; not yet accepted; Wessels & Wilhelmi, Hamburg, July 26, 1922.)

Hydrocarbons — Low-boiling hydrocarbons are produced by heating mineral oils, tar oils or other hydrocarbons under pressure in presence of hydrogen and a metal or alloy which melts at the reaction temperature. Soldering metals and bismuth alloys melting below 700 deg. C. are specified. (Br. Pat. 180,625; not yet accepted. M. Melamid, Freiburg. July 19, 1922.)

Inhibiting Oxidation—The oxidation of substances by the air—for instance, oils, essences, resins, animal tissues, latexes and rubber—is prevented or inhibited by the addition of a small proportion of a phenolic body, added in the form of solid, solution or vapor. According to the examples, styrolene, furfurol and acetaldehyde are stabilized by the addition of a solution of pyrogallol or guaiacol. The addition of hydroquinone to vegetable oils, such as linseed oil or nut oil, prevents their turning rancid. (Br. Pat. 181,365, not yet accepted. C. Moureu and C. Dufraisse, Paris. Aug. 2, 1922.)

Dye Embargo and Potash Rates Stumbling Blocks in Final Tariff Debate

Bill Passes House After Conferees, as Instructed, Reverse Their First Action—Dye Embargo Killed and Potash Put on Free List

THE House of Representatives adopted the conference report on he Fordney-McCumber tariff bill on Friday, Sept. 15, after refusing to ecommit the report with instructions o reduce the rate on sugar. The re-ort came back to the House shorn of he dye embargo and potash tariff pro-isions, and an agreement was speedily eached to limit the general discussion n the report to one hour, divided equally between the Republicans and he Democrats.

Dye Rates

Chairman Fordney of the committee explained the action taken by the conferees to bring the report into conformity with the demands of the House. Intermediate coal-tar products were subjected to an ad valorem of 55 per cent and finished products to an ad valorem of 60 per cent, with an additional specific of 7c. per pound in each case. These rates are to remain in operation for two years, when each of the ad valorems will be reduced by 15 per cent. He was assisted by Representative Longworth, Republican, of Ohio, at whose insistence the dye embargo provisions were originally written into the bill.

Longworth Disappointed

"I do not deny that I was very greatly, even bitterly, disappointed at the result on Wednesday on the motion of the gentleman from Texas," said Mr. Longworth. "I am perfectly convinced that the restoration of potash to the free list means the absolute destruction of the industry in this country.

"I was even more bitterly disappointed at the action of the House in striking out the so-called dye embargo. That was not an embargo, for all the dyes that were necessary for any of the consumers of dyes in this country, which were not produced here and were not sold at a satisfactory price, could be imported in any quantity. Under this so-called embargo about 3,000 different dyes have been imported into this country within the last 6 months. They have been coming in ever since we have had this system and would have continued to do so if the system had been made permanent."

Numerous changes were made in the chemical schedule by the conference committee. As a general proposition, the Senate amendments to the chemical schedule were accepted. The bill as a whole is a Senate tariff. Of the 2,436 amendments, important and unimportant, which confronted the conferees, the Senate conferees receded from 71, 303 were compromised, and the House conferees agreed to 2,062 Senate changes.

Organic Acids

The conferees fixed a rate of 17c. per pound on citric acid, the House rate having been 12c. and the Senate rate 18c. Senate action in placing white arsenic on the free list was approved. The conferees struck out the Senate's rate of 4c. per pound on formic acid, with the effect of placing it in the basket clause at 25 per cent ad valorem, which was the House duty.

Alcohol

Senate action in making a rate of 3c. per pound on propyl alcohol was disagreed to and the House rate of 6c. was restored. The House rate of 6c. per pound on fusel oil was restored, in place of the Senate rate of 2c. A compromise rate of 12c. per gallon on methyl or wood alcohol was reached. The House rate of 15c. per gallon was restored on ethyl alcohol for non-beverage purposes.

Barium Salts

House rates on barium compounds were made lower than the Senate rates. These rates are 1c. per pound on carbonate precipitate; 1¼c. per pound on chloride; 4c. per pound on dioxide; 1¼c. per pound on hydroxide and 2c. per pound on barium nitrate. Comparative rates in the Underwood law were from one-fourth of a cent per pound to 15 per cent ad valorem. The duty in the Payne-Aldrich bill was 25 per cent ad valorem.

Camphor

The conferees did not change the rate of 1c. per pound on crude natural camphor and 6c. per pound on refined or synthetic camphor, but they eliminated the Senate amendment which would have imposed a duty of 25 per cent ad valorem whenever it could be shown to the satisfaction of the President that the production of synthetic camphor in the United States reaches

(Continued on page 616)

New Efforts Made for Dye Embargo

House Is Asked to Bar Imports for Three Months After Tariff Goes Into Effect

Although the provision inserted in the conference report on the tariff for another year's dye embargo, and possibly two, was denounced by the House, and overwhelmingly rejected last week, a new embargo plan appeared in Congress on Saturday, Sept. 16, to overcome the tariff agreement before it has been accepted by the Senate.

Representative Tilson of Connecticut introduced a joint resolution to extend the embargo 3 months. Senator Wadsworth of New York is sponsor for the resolution in the Senate. The House resolution reads:

> The dye and chemical control act of 1921, as extended, shall continue in full force and effect for 3 months after the date on which the tariff act of 1922 becomes effective, any provision in such act notwithstanding.

To Meet Administrative Difficulties

It is said that the agreement for an American valuation on dye duties is cumbersome and cannot be used by the customs officials at once, hence it is sought to have the embargo extended 3 months after the tariff goes into effect. This contention, placed before the Finance Committee by Treasure officials, is backed up by a letter from Secretary Mellon.

Secretary Mellon, in his letter written to Senator McLean of Connecticut, calls attention to the difficulties the customs officials will have in determining the American values, and says they should not be called upon to administer the American valuation system as to dyes immediately. He suggests, it is said, that some time be allowed for these officers to work out the American values on the different dyes.

King Will Not Oppose

Those favoring the extension of the embargo 3 months approached Senator King of Utah, a severe anti-embargo Senator, and asked him whether he would continue his opposition to the embargo as proposed in the joint resolution. His reply was that he was not disposed to do so if assured that the request was actually based upon administrative difficulties, and was not the forerunner of another move for a further extension when the 3 months' period expired. It is said that the dye interests would not give Senator King a definite promise that they would not seek another extension.

Eight-Hour Shift Recommended

Federated American Engineering Societies' Committee Reports 25 Per Cent Production Increase by Change From Twelve- to Eight-Hour Day

"THE tendency throughout the world is toward the abolition of the 12-hour shift," it is held by the report of the committee on work-periods of the American Engineering Council of the Federated American Engineering Societies, which was adopted after a long discussion by the executive board of the Council in Boston, Friday, Sept. 8. The report, in effect, finds that the two-shift day of 12 hours each is not an economic necessity in American industry.

"In almost every continuous industry," says the report, "there are plants which are operating on an 8-hour shift basis in competition with 12-hour shift plants." It is also shown that in practically every major continuous industry plants which have changed from 12 hours to 8 hours have increased the quantity of production per man up to as much as 25 per cent. In a few cases, the report states, the increase has been much higher. In the steel and iron industry, which is made the subject of a special report, it was found that "the change from the 12- to the 8-hour day has obtained results sufficient to compensate in whole or in part for the extra cost."

Advantages of 8-Hour Day

Other advantages of the 8-hour day in the steel and iron industry are described as increased efficiency, better morale, elimination of the "floating gang," which is maintained to give 12-hour men a day off a week, and greater prestige of the industry with the public.

Prof. Samuel McCune Lindsay of Columbia University, representing the Cabot Fund of Boston, officially styled the report as embodying the results of "the most important investigation of any industrial situation ever undertaken in this country." The Cabot Fund cooperated in the engineering investigation, which occupied nearly 2 years and covered practically every continuous industry in the United States. Professor Lindsay, who is president of the Academy of Political Science, authorized the statement that Prof. Henry R. Seager of Columbia, president of the American Economic Association, shared his general view.

All Major Industries Surveyed

The results of the industrial investigation, which, engineers said, will exercise a great influence on the general labor situation, were obtained through two lines of inquiry. One inquiry, embracing the steel and iron industry of the country, was directed by Bradley Stoughton of New York, former secretary of the American Institute of Mining and Metallurgical Engineers and former adjunct professor of metallurgy in Columbia University.

The second inquiry was directed by Horace B. Drury, industrial investigator and former member of the faculty of Ohio State University. Each inquiry was made the subject of a separate report, the whole investigation being in charge of the Council's committee on work-periods, of which Dr. H. E. Howe of Washington is chairman. Dr. Howe presented the report to the board. His associates on the committee are J. Parke Channing, L. P. Alford, Fred J. Miller and Dwight T. Farnham of New York; Morris L. Cooke of Philadelphia, and L. W. Wallace of Washington.

Presentation of the report by Dr. Howe caused a spirited discussion of 2 hours, during which President Cooley, urging adoption, asserted that the report was a remarkable contribution of the engineering profession toward the advancement of mankind. Others participating in the debate were Philip N. Moore of St. Louis, Prof. Joseph W. Roe of New York University, Irving E. Moulthrop of Boston and W. W. Varney of Cleveland, Calvert Townley of New York, E. S. Carman of Cleveland, John A. Stevens of Lowell, William Rolfe of St. Louis, and Messrs. Channing, Alford and Wallace, representing the committee on work-periods. The report was finally adopted by an overwhelming vote.

Iron and Steel Industry

The Stoughton report, covering iron and steel, asserts that the fact that already many plants operate successfully on the three-shift system indicates that profits need not suffer if the change is made with wisdom. The Stoughton report continues:

"The cost of all labor on either system at the blast furnace is less than $1 per ton of pig. Judge Gary testified before the Lockwood committee in New York in June, 1922, that the U. S. Steel Corporation could produce at $2 per ton less than its competitors. That shows what low overhead and technical skill can accomplish.

"The operating labor in the case of pig iron is from 5.8 to 8 per cent of the total manufacturing cost. Only a part of the labor in the industry is working the 12-hour day. If that labor was changed to the 8-hour day and paid as much per day as it is now getting for 12 hours work, even without securing any compensating advantages through increased efficiency, morale, etc., the total manufacturing cost of the product would be increased only from 3 to 15 per cent.

"This is in most cases less than the variations in cost already experienced by competing plants, due to difference in efficiency of equipment, technical skill, purchasing, location, capital resources, overhead expense and advantages due to good management.

The Stoughton Report

The Stoughton report finds that the 8-hour day makes better men physically and mentally, attracts a better class of men to the industry, improves conduct of operation, makes operation more uniform, betters the quality of product, uses less fuel, involves less waste and less repairs to equipment, and lengthens the life of apparatus. These advantages, the Stoughton report says, are bound up in "increased efficiency manifested in increased production per man per hour and per machine per day."

The 8-hour day, it is declared, produces better morale among workers, resulting in less absence and tardiness, less shirking and better discipline, which results from "better spirit of the men and the greater pressure which foremen can and will exert because they do not have to hold back out of sympathy for tired men."

According to the Stoughton report, which deals with the change from the 12-hour shift to the 8-hour shift in the iron and steel industry, there are altogether about 150,000 wage earners in the entire steel industry on 12-hour shifts.

The report makes recommendations for successful and economic change from the two-shift operation.

Chemical Engineers Dine Under Difficulty

Lack of Food Fails to Dampen Enthusiasm of Social Gathering

About seventy-five members of the American Institute of Chemical Engineers gathered at the Hotel Pennsylvania at dinner on Thursday of exposition week. There was the usual air of genial animation about the festive board and even when the dinner apparently gave out between entrée and dinner course, the diners scarcely noticed it. Finally Dr. Wesson went out and returned with the head waiter's scalp. Then food began to flow again. President Howard announced that at Council meeting it had been decided to hold the fall meeting at Richmond, Va. The membership and cash balances were reported to be in good condition and then Dr. Wesson was asked to tell the members something about Richmond. Tobacco and other large factories in the immediate vicinity, and Hopewell, within a day's excursion, make the prospect promising.

H. C. Parmelee urged the members to take an active interest in the law which has to do with the licensing of engineers. He expressed satisfaction that a committee of the Institute had been authorized to work with the Mining Engineers for the repeal of the law in New York State. J. V. N. Dorr was asked to give some impressions of Europe gathered on his recent trip. The dinner then broke up into groups, but very few broke away to go back to the exposition.

Take Fresh Start on Muscle Shoals

Engineers to Appoint Committee to Make Impartial Survey of Situation

The organized engineers of the country will attempt to solve the problems of Muscle Shoals. Through the executive board of the American Engineering Council at its closing session in Boston, Friday, Sept. 8, the Federated American Engineering Societies adopted a resolution authorizing the appointment of a committee of leading engineers to study thoroughly every phase of the Muscle Shoals problem in order to clear away what was described as "a hopeless muddle" which might lead to grave national disadvantage.

The board was moved to this action by the representatives of the Associated Engineering Societies of St. Louis, William E. Rolfe, city engineer of St. Louis, and Philip N. Moore, chairman of the War Minerals Relief Commission. In a spirited speech supporting the resolution, Mr. Moore denounced the proposal of Henry Ford, citing figures tending to show that acceptance of this proposal by the government would be unwise.

Biggest Volunteer Enterprise

The president of the Federated American Engineering Societies, Dean Mortimer E. Cooley of the University of Michigan, was directed "to appoint a committee of disinterested, distinguished and skillful engineers, to be selected by a special committee of the executive board and approved by the committee on procedure, for the purpose of making a thorough study of the assembled facts regarding the Muscle Shoals proposition, this committee to serve without compensation."

The Muscle Shoals resolution provides that the committee of engineers chosen to make the study "shall submit to the committee on procedure, and subsequently to the executive board, an outline of the scope of the investigation proposed."

The resolution, which gets under way one of the biggest volunteer enterprises ever undertaken by American engineers, declares that the results of this study will constitute "a service of great and possibly determinative value to the nation" in the settlement of the controversy over Muscle Shoals.

Calvert Townley of New York, vice-president of the Westinghouse Electric & Manufacturing Co. and past president of the American Institute of Electrical Engineers, is chairman of the committee on procedure, which will finally approve the personnel of the committee of engineers chosen. Other members of the committee are Dean Dexter S. Kimball of Cornell University, president of the American Society of Mechanical Engineers; J. Parke Channing of New York, mining engineer, prominent in the copper industry; W. E. Rolfe, St. Louis; W. W. Varney, Baltimore; H. E. Howe, Washington. President Cooley stated that concerted effort will be made to place at the disposal of the nation the services of America's best engineers.

This action by the executive board is the outcome of an attempt made 6 months ago by Mr. Moore at a meeting of the board in Chicago to enlist the impartial skill of the engineers in the Muscle Shoals proposition.

The executive board at its final sessions passed upon a great variety of questions of national engineering, social and political importance. In adopting the report of the committee on reforestration, presented by Chairman Charles H. MacDowell of Chicago, the engineers approved plans to extend the co-operation of their profession to the nation-wide movement to save the nation's forests. The engineers will work with the federal and state forestry services, farmers' organizations, the Boy Scouts and other bodies in the reforestration campaign. The aid of Will H. Hays also will be sought in an effort to acquaint the masses of the people with the danger to future generations of denuding the forests.

Favor Registration for Engineers

Gardner S. Williams of Ann Arbor, Mich., and W. B. Powell of Buffalo were appointed to draft a bill calling for the registration of engineers. This bill will incorporate the recommendations of the American Engineering Council's committee on registration of engineers.

In view of the expanding into national activities of the Council, Dr. William McClellan of Philadelphia, past president of the American Institute of Electrical Engineers, was added to the committee on foreign relations. Prof. James R. Withrow of Ohio State University was elected to the committee on membership and representation.

The executive board approved the universal contract form for building construction devised by the Department of Commerce. The board adjourned to meet in Washington on Jan. 4, when the annual meeting of the American Engineering Council also will be held. The members of the board were luncheon guests at the City Club of the Boston section of the Society of Civil Engineers.

Alpha Chi Sigma Entertains Exposition Guests

About fifty members of Alpha Chi Sigma, the professional chemical fraternity, were the guests of their New York brothers at the annual dinner given Sept. 14 in connection with the Eighth National Exposition of the Chemical Industries. Short talks were made by the principal national officers of the fraternity, including Stroud Jordan, of Brooklyn, its president; Arthur L. Davis of Wood River, Ill., secretary and treasurer; and Paul D. V. Manning, editor of the fraternity's monthly publication *The Hexagon*. A feature of the gathering was an account of the founding of the society given by F. J. Petura, general purchasing engineer, Henry L. Doherty Co. of New York.

Equipment Makers Perfect Association

Chemical Equipment Association Elects Officers and Discusses Relation to Exposition

At a meeting held in the Chemists' Club on the evening of Sept. 12, the manufacturers of chemical equipment and accessory plant apparatus formally adopted a constitution and bylaws and elected officers, thereby perfecting an organization that has been in the formative stage for the past year.

The constitution and bylaws were adopted as printed in *Chemical & Metallurgical Engineering*, p. 947, May 17, 1922, with the exception that provision was made for regional vice-presidents and for the separation of the office of secretary-treasurer, the secretary to be employed by the board of directors and to give his entire time to the work of the organization. The officers elected under this plan were: President, Pierce D. Schenck, Duriron Co.; vice-presidents, Walter E. Lummus, Walter E. Lummus Co.; Adolph Coors, Jr., Coors Porcelain Co.; George J. Lehman, Bethlehem Foundry & Machine Co.; treasurer, P. C. Kingsbury, General Ceramics Co.; directors—H. N. Spicer, Dorr Co.; J. I. Lyle, Carrier Engineering Corp.; P. S. Barnes, Pfaudler Co.; Edward C. Alford, T. Shriver & Co.; T. C. Oliver, Chemical Construction Co.; H. H. Alport, E. B. Badger & Sons Co.

It was announced that thirty-two firms have joined the association as active members and that four representatives of the business and technical press have taken associate membership.

A lively discussion was precipitated when the aims and objects of the association were discussed for the enlightenment of some of those present. When these points were cleared up by reference to the objects as stated in the constitution and through speeches of members who have been particularly active in the organization of the association, it developed that there was some misapprehension regarding the relation of the association to the Chemical Exposition. Some of those present expressed the sentiment that the association should take up with the management of the exposition certain questions relating to exhibitors' interests. It was stated emphatically by George Lehman that this had not been considered the primary purpose of the association and that it would not be undertaken except by direction of the members, now that the association is formally organized. Further discussion on the floor brought out the fact that it would be highly inadvisable for the association to engage in a controversial matter, particularly at its inception. This view finally prevailed and resulted in a decision to leave the satisfactory settlement of the relations between exhibitors and the exposition management to some other medium. Plans were immediately made for an active campaign for new members during exposition week.

Regulate Production of Coal, Says Hoover

Secretary of Commerce Addresses Chemical Salesmen's Association at Big Dinner

About 300 members of the Chemical Salesmen's Association and their guests celebrated the first anniversary of the founding of the association at dinner at the Hotel Commodore on Tuesday, Sept. 12. A very jazzy orchestra enlivened the dinner and a great many songs, old and new, were sung with more or less discord but much enthusiasm. The newly elected president of the association, Mr. Boyer, introduced Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers' Association, as toastmaster. Dr. Herty introduced Secretary of Commerce Hoover, who addressed the association on the coal industry.

Mr. Hoover analyzed the troubles now extant in the coal industry and attributed them in part to the overproductive capacity of the industry. The 8,000 and more bituminous mines in this country can produce 50 per cent excess coal over that consumed during any given year. In other words, the industry can produce about 800,000,000 tons of coal, whereas about 500,000,000 tons is all that has ever been produced. This means that the average miner, not including the time he is on strike, is employed only 40 per cent of the time during the year, and this in turn means that the American public pays its miners a living wage for working less than 60 per cent of the time. The big problem of the industry then is to absorb or adjust in some way this overproduction. Secretary Hoover did not anticipate the findings of the commission, but went on to say that the creation of the commission which will be appointed by the President when the bill on this subject has been passed will be the most constructive step toward the solution of this whole situation, a situation which has been becoming more and more aggravated and which during the last 4 or 5 years has reduced 100,000,000 people to a point of industrial collapse for want of a prime necessity. Mr. Hoover's speech was most enthusiastically received by the association.

Banker Optimistic

In introducing S. H. Sisson, vice-president of the Guaranty Trust Co., who was the next speaker, Dr. Herty pointed out that the bankers had been quite cold on the whole toward the chemical industry, but expressed the belief that with legislation in their favor and a substantial business basis established, the bankers would collaborate with the chemists in establishing this vital industry on a firm basis.

Mr. Sisson took occasion to outline the factors which are both favorable and unfavorable in the industrial and economic situation of today. His summary was an optimistic one, since he felt that the normal productive capacity of this country will return and with it the buying power of the consumers. This, he felt, will more than counterbalance the instability of foreign exchange, the political isolation of the United States, the existence of wars, the discord among the allied powers and many other unfavorable factors. It will not be smooth sailing, but a hard and earnest effort in which the salesmen of the country will be a prominent factor in working out the success of the movement.

Tariff Bill in Final Stage

(Continued from page 613)

2,000,000 lb. a year. This amendment, based on production, was proposed to encourage development of the synthetic camphor industry principally by a St. Louis chemical company which embarked on this enterprise during the war and has since met stiff competition from the Japanese camphor monopoly.

Bleaching Powder

A compromise rate of three-tenths of a cent per pound was fixed on bleaching powder, or chlorinated lime. The Underwood rate was one-tenth of a cent, while the Payne-Aldrich rate was one-fifth of a cent. The Senate had proposed one-fifth of a cent and the House rate was three-fifths.

Vegetable Oils

Rates on vegetable oils were reduced by the conferees below the figures fixed in the Senate. Linseed oil was cut to $3\frac{5}{16}$c. per pound from $3\frac{1}{2}$c., the House rate having been $2\frac{1}{2}$c. Coconut oil was cut from 4c. to 2c. per pound and soya-bean oil from 3c. to $2\frac{1}{2}$c. per pound.

In comparing House and Senate ad valorem rates, or House ad valorems and those which appear in the final form of the bill, it must be recalled that the original House duties were based upon the American selling price, while the Senate ad valorems and those which appear in the new bill as completed were based upon the foreign price.

Personal

Dr. George Barsky, formerly a research assistant of Prof. Ralph H. McKee, department of chemical engineering, Columbia University, has been appointed to a position in the research department of the Abitibi Paper Co., Abitibi, Ont.

E. B. Benger has been appointed as chemical director of the Newburgh plant of E. I. du Pont de Nemours & Co. He was formerly director of the Redpath Laboratory at Parlin, N. J.

C. W. Crowell has recently resigned as chemist for the California-Hawaiian Sugar Refining Co., Crockett, Calif., to become plant superintendent at the works of the Rochester Germicide Co., Rochester, N. Y.

Dr. Ralph T. Goodwin, who took his degree this summer in the department of chemical engineering of Columbia University, has been appointed to a position in the research department of the Standard Oil Co. of New Jersey. Dr. Goodwin will have as his special concern the shale oil interests of that company.

Prof. Henry LeChatelier of Paris, France, has been elected to honorary membership in the American Society for Steel Treating.

E. W. McCullough has resigned as director of the division of mining and metallurgy, Republic Creosoting Co., to accept an appointment as consulting engineer for refuse disposal with the Indianapolis City Sanitary Commission. This work will involve the design and construction of a plant.

Vladimir Tuma, chemical engineer, has accepted a position with the B. F. Goodrich Co., Akron, Ohio, as the director of the technical library.

Obituary

Prof. Alexander Smith, formerly head of the department of chemistry at Columbia University, died at Edinburgh, Scotland, on Sept. 9. He was the son of Alexander W. Smith, a well-known musician of Edinburgh, where he was born on Sept. 11, 1865. He took his Bachelor's degree at the university of that city in 1886, and his Doctorate in Philosophy at Munich in 1889. He returned to the University of Edinburgh immediately, and for a year was assistant in chemistry at that institution, coming to America the following year to become professor at Wabash College, where he remained until 1894. Then he was called to Chicago, where he made a brilliant career, and in 1911 he was called to Columbia to become head of the department. He was a great teacher and the author of textbooks that became standard all over the world. Everyone knows his "Introduction to General Inorganic Chemistry," and his "General Chemistry for Colleges" has also been widely studied. Most of his works were translated into German, Russian, Italian and Portuguese, and are also extensively used where these languages are spoken. About 3 years ago while addressing a class he was overtaken by a fainting spell and shortly afterward was operated on for a tumor in his stomach. Following the operation he suffered from such intense depression that he was unable to take up his work, and he was an invalid from that time on. He worked with great intensity and used himself up in the process. We are glad to say that his "Inorganic Chemistry" has lately been thoroughly revised and brought down to date by Prof. James Kendall and others, so that its splendid qualities of order and exposition will not be lost to future students. He leaves a widow, formerly Miss Sarah Bowles of Memphis, Tenn., and two children.

Prevailing Prices and Market Letters From Principal Industrial Centers

Sulphuric Acid and Acid Phosphate Used in the Manufacture of Fertilizers

Statistics for Production, Stocks and Sales Reported by 198 Fertilizer Establishments, of Which 69 Manufactured Sulphuric Acid

ESTABLISHMENTS representing practically all of the fertilizer industry, with the exception of the dry mixing plants, have recently effected a co-operative arrangement with the Ceusus Bureau of the Department of Commerce whereby statistics of production and consumption are to be compiled and published twice each year. This marks the first step toward the compilation and distribution of current statistical information for this very important industry.

These data for the first 6 months of the current year are to be found in Tables I and II. From these tabulations it will be noted that the manufacturers of fertilizer producing sulphuric acid and acid phosphate had on hand Jan. 1, 1922, 129,610 net tons of sulphuric acid (basis of 50 deg. Bé.) and during the 6 months ended June 30, 1922, they produced 560,351 tons, consumed in the manufacture of fertilizer 650,189 tons and they had on hand June 30, 108,955 tons. The purchase of sulphuric acid during the 6 months period exceeded the sales by 155,429 tons.

Acid Phosphate Stocks

The same establishments reported that their stocks of acid phosphate on Jan. 1, 1922, amounted to 2,129,339 net tons, containing 32,818,093 units of available phosphoric acid, averaging 15.9 per cent. There was manufactured during the 6 months period 1,198,724 tons, containing 20,104,992 units, averaging 16 8 per cent. During the 6 months there was sold as acid phosphate, in bags and in bulk, 1,053,437 tons, containing 17,533,284 units of available phosphoric acid, averaging 16.8 per cent and there was used in manufactured goods sold 1,031,240 tons, with 15,523,095 units, or 15.1 per cent, making a total of acid phosphates sold as such or in manufactured goods of 2,378,424 tons, with 38,726,884 units of available phosphoric acid.

These data are compiled from reports made from 198 fertilizer establishments, of which 69 manufactured sulphuric acid. The next report will cover the 6 months ending Dec. 31, 1922.

TABLE I—PRODUCTION, SALES AND INVENTORY OF SULPHURIC ACID; (BASIS 50 DEG. BAUMÉ), JAN. 1 TO JUNE 30, 1922

	Net Tons
On hand Jan. 1, 1922	129,610
Manufactured	560,351
Total	689,961
Incoming shipments, on purchases *	245,081
Outgoing shipments, on sales to fertilizer manufacturers*	89,652
Net excess purchases over sales	155,429
Outgoing shipments, on sales for other purposes than making fertilizers	84,544
Used in making fertilizers	650,189
On hand June 30, 1922	108,955

* For the purpose of this compilation, transfers from or to other plants of the same company are reported as purchases or sales, as the case may be.

TABLE II—PRODUCTION, SALES AND INVENTORIES OF ACID PHOSPHATE, JAN. 1 TO JUNE 30, 1922

	Net Tons	Available Phosphoric Acid Total Units*	Per Cent Ave.	Per Cent Range
Inventory Jan. 1, 1922	2,129,339	32,818,093	15.9	.....
In pile as acid phosphate	1,490,332	25,469,294	17.1	15.3–18.0
In base and complete goods	639,007	7,348,799	11.5	6.5–24.0
Purchased	47,047	813,541	17.3	10.0–44.6
Transferred from other plants of same organization	34,554	513,353	14.9	3.1–36.0
Manufactured (made in plant reporting)	1,198,724	20,104,992	16.8	15.0–19.0
Total	3,409,664	54,249,979		
Sold as acid phosphate	1,053,437	17,533,284	16.8	.....
In bags	666,095	10,912,739	15.9	15.0–19.0
In bulk	387,342	6,620,545	17.1	14.4–18.0
Transferred to other plants of same organization	145,232	2,347,736	16.2	8.0–18.2
Inventory June 30, 1922	1,179,755	18,845,864	16.0	.....
In pile as acid phosphate	929,783	15,916,740	17.1	13.6–20.0
In base and complete goods	249,972	2,929,124	11.7	6.0–29.2
Total sales, transfers, and inventory	2,378,424	38,726,884		
Used in manufactured goods sold	1,031,240	15,523,095	15.1	.....

* A unit equals 20 lb. Total units, tons multiplied by per cent.

Exports and Imports of Chemicals

Statistics for July Show Export Trade Continuing on an Even Keel, With an Appreciable Decline in Imports

Exports of chemicals during July continued in approximately the same volume as during June. The total of chemical and allied products exported in July were valued at $8,463,366. The value of the purely chemical exports was $4,378,678. The total which includes the allied products is more than $2,000,000 greater than in July of 1921, whereas the value of chemical exports alone exceed those of July, 1921, by $1,300,000.

The July figures show the value of all exports of fertilizers and fertilizer materials to have been $1,082,850. Pigments, paints and varnishes were exported to the extent of $855,193. The value of explosives exports was $329,031. Exports of sulphate of ammonia increased from $95,633 in July of 1921 to $647,259 in July of 1922. The exports of caustic soda increased from 3,352,295 lb. in July of 1921 to 7,829,303 lb.

Exports of certain other chemicals in July were as follows: benzol, 18,282,045 lb.; acetic acid, 1,179,239 lb.; sulphuric acid, 1,034,756 lb.; boracic acid, 152,104 lb.; aluminum sulphate, 2,482,821 lb.; acetate of lime, 3,115,168 lb.; calcium carbide, 1,546,995 lb.; chloride of lime, 4,805,388 lb.; copper sulphate, 294,639 lb.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	146.67
Last week	146.67
September, 1921	147
September, 1920	267
April, 1918 (high)	286
April, 1921 (low)	140

By rare coincidence this index number has shown no change for the past week. Higher prices for citric acid, barium chloride and salt cake exactly balanced decreases due to lower prices for caustic soda and aniline oil.

Due to the interest in the exports of caustic soda at this time, the July forwardings to the different countries are set forth in detail as follows:

Countries of Destination	Quantity in Lb.	Countries of Destination	Quantity in Lb.
Denmark	100,142	French West Indies	1,120
Finland	33,000	Argentina	295,786
Germany	711,819	Brazil	842,544
Iceland	200	Chile	372,026
Italy	940,225	Colombia	117,443
Netherlands	158,324	Ecuador	13,700
Portugal	22,400	Peru	103,800
Canada	755,103	Uruguay	93,320
Costa Rica	21,204	Venezuela	38,093
Guatamala	6,640	China	407,238
Honduras	22,300	Java	282,990
Nicaragua	24,100	Hongkong	46,200
Mexico	595,726	Japan	345,840
Trinidad	5,963	Persia	8,000
Other British West Indies	45	Philippines	804,825
Cuba	586,531	Australia	43,680
Dominican Republic	6,700	Other Oceania	68
		Brit. So. Africa	3,160

Imports Decline

The imports of chemicals in July declined appreciably. The total value of chemicals on the free list imported in July was $6,021,730, while those on the dutiable list were valued at $3,365,518. This is a decline of $800,000 on the free list chemicals and over $1,000,000 on the dutiable chemicals. The totals in each instance, however, are materially larger than they were in July of 1921.

The imports of gums alone are responsible for a decline of more than $1,000,000. The total imports during July were valued at $1,961,353, whereas in June the value of the gum imports reached the unusual total of $2,994,463. Coal-tar products declined from $1,455,345 in June, 1922, to $809,638 in July. The following chemicals were imported during July in the quantities shown: muriate of ammonia, 813,323 lb.; sulphide of arsenic, 826,871 lb.; calcium salts, 6,746,896 lb.; benzol, 432,683 lb.; creosote oil, 3,898,528 gal.

The New York Market

New York, Sept. 17, 1922.

The domestic consumer has shown a greater buying interest during the past week and several price advances were recorded among leading interests. The approaching enactment of the new tariff has kept sellers somewhat cautious in booking any future business, but has stimulated speculation on the more important items. Importers are turning down shipment orders and are in fear of having a last-minute change in the tariff rate on some commodity already afloat. The present situation, in general, is very unsteady in the face of these adverse circumstances, and real tonnage business was not transacted during the interval. Producers in most instances were accepting orders for limited quantities only and consumers had to be contented with these allotments. The coal strike settlement was considered a distinctly favorable feature and recent rail peace negotiations were also regarded as an incentive to increased business. The last quarter seems to be considerably more active, and leading interests are of the opinion that business conditions will show a tremendous increase over the previous months. Copper carbonate was advanced 1c. per lb. by producers. Bleaching powder is heavily sold up for near future requirements and spot supplies are in a very strong position. Oxalic acid has ruled very steady since recent advances. Nitrite of soda was advanced during the week and considerable speculation has been noticed among prominent jobbers. Imported sulphide of soda was higher on spot, while shipment material was practically unobtainable. Sulphate of ammonia continues exceedingly strong and spot stocks for export are limited. Salt cake was quoted higher and so was red prussiate of potash. Domestic inquiry for caustic soda and soda ash continues heavy and a much larger volume of business was transacted during the past week. Yellow prussiate of soda was not as active as last week, but price changes were only fractional. Citric acid has been another of the features of the week's trading. Spot goods have been completely bought up and prices were materially advanced.

General and Special Chemicals

Acetate of Lime—The general tone is very firm and producers continue to quote $2.35 per 100 lb. The demand is steady and supplies seem to be sufficient to cover only regular orders.

Barium Carbonate and Chloride—Supplies of both products were very scarce on spot and the general condition appears much firmer. Importers of carbonate quote $65 per ton as an inside figure and hold chloride at $93 @$95 per ton.

Bichromate of Soda—Leading sellers were not eager to quote under 7½c. per lb. The demand was somewhat active for domestic consumption. The export market was irregular.

Carbon Bisulphide—Producers report a fair call for moderate quantities, with quotations held around 6¾@7c. per pound.

Carbonate of Copper—Producers advanced quotations to 20c. per lb. as an inside price and 21c. per lb. for smaller quantities. This represents an increase of 1@2c. per lb. over recent figures.

Caustic Soda—Leading interests are quoting export material at $3.55 per 100 lb. Material for domestic requirements is held around $3.75@$4 per 100 lb. Producers report moderate new business for contract at recent levels.

Nitrite of Soda—Both the domestic and imported goods have shown new strength and inside quotations range around 9c. per lb. Recently dealers have become interested and strong speculation has been noticeable.

Prussiate of Soda—Spot goods were somewhat easier during the latter part of the week, although there were no price reductions. Figures ranged around 23½@24c. per lb.

Salt Cake—Leading interests quoted higher prices for spot and shipment goods. The demand has shown a decided improvement and the lowest price heard was around $23 per ton, f.o.b. works.

Sulphide of Soda—Imported goods were advanced on spot, with 4¼c. per lb. the lowest price heard during the latter part of the week. Shipment material was practically sold up. Domestic factors quote fused 60-62 per cent at 4½ @5c. per lb.

Vegetable Oils

Castor Oil—Leading factors continue to quote the U.S.P. grade at 13c. per lb. and commercial at 12½c. The demand was moderate, with producers holding prices quite firm.

Coconut Oil—There were several transactions during the week for carload lots of Ceylon type at 7½c. per lb., nearby delivery. Ceylon type on spot closed around 8¼@8½c. per lb. Cochin type oil held at 8¾@9c. per lb.

Linseed Oil—The general condition of the market was unchanged from previous reports. Trading in prominent quarters showed very little improvement and spot prices ranged around 88c. per gal., in carload quantities. Imported oil sold at 72c. per gal., prompt shipment. Spot imported oil held around 82c. per gal. Interest in foreign goods was lively during the early part of the week, but later lessened appreciably.

The Metal Markets

Copper and zinc were quite active during the week. One of the notable features has been the advance in antimony. The high tariff rates reported by the conferees have also influenced other metals and the situation, in general, has shown a notable tendency toward livelier trading. Quicksilver and antimony have already reflected the tariff in their new prices. The official contract price of the American Smelting & Refining Co. continues at $5.90 New York. Sales have been quite satisfactory during the interval, due to the reluctance of the chief producers to make quotations. Leading copper producers quoted 14c. delivered. Several large tonnage sales were transacted at this level and the majority of sellers were inclined to hold prices firm at this level. An active market has advanced zinc prices. Sales were noted during the week around $6.40 for prompt shipment. A serious shortage is imminent if consumption keeps up at the present rate and production in leading quarters shows no sign of increasing.

Chilean Saltpeter Exports Show Increase for July

Chilean nitrate sales are increasing, according to a report to the Department of Commerce. July exports of nitrates are in excess of those effected during the month of June and the fact that the nitrate association's sales for future delivery subsequent to June 30 now approximate 500,000 tons presages increased exports during the coming months. A rumor is current to the effect that Germany is negotiating for 600,000 tons to supply a shortage resulting from its deficient production of synthetic nitrate.

The Chicago Market

CHICAGO, ILL., Sept. 14, 1922.

The industrial chemical market was steady and strong during the past 2 weeks. Buying interest continued on a good scale accompanied by price advances on several important items. There was a pronounced scarcity of spot supplies on quite a few items and this, coupled with the uncertainties of future deliveries, forced prices upward. A good increase in the volume of orders received was reported by several concerns, with practically no one offering any complaints.

General Chemicals

Caustic soda continued firm, with only moderate supplies available. The solid 76 per cent material was offered in one direction today at $3.25 per 100 lb. and the ground from the same source at $4.25. *Caustic potash* was in moderate demand, with spot goods offered at 6½c. per lb., basis 88-92 per cent. *Soda ash* moved in the regular channels at $2.25 per 100 lb. for material in cooperage.

Potash alums moved in a good volume and prices were steady. The iron-free lump was quoted at 5@5½c. per lb. and the powdered at 5½@6c. *Sal ammoniac* maintained a firm position and spot material was available at 7¾c. per lb. for the white granular. *Barium carbonate* was firm, with only moderate supplies available for immediate delivery at $80 per ton. *Barium chloride* continued firm and was offered at $110 per ton. *Bleach* was quoted higher at $2.35 per 100 lb. ex-warehouse and was reported to be moving very well. *Copperas* was firm and scarce, with small lots of the crystals offered at $1.40@$1.60 per 100 lb. ex-warehouse. *Copper sulphate* was very firm and moderate supplies were available at 6½c. per lb. *Carbon bisulphide* was rather scarce on spot and holders were reluctant to shade 7½c. per lb. *Carbon tetrachloride* was unsteady and supplies could have been purchased at 8½@9c. per lb. *Formaldehyde* was in a very firm position due to the strength of methanol and was quoted higher at 9½c. per lb. for barrels. *Furfural* was unchanged at 35c. per lb. in 1,000-lb. lots. *Glycerine* was very firm and refiners advanced their prices to 17½@18c. per lb. for the c.p. material in drums. *Lead acetate* was unchanged and supplies were offered at 11@12c. per lb. for the white crystals. *Magnesium metal powder* was offered at the lower figure of $1.20 per lb. for 100-lb. lots.

The coal shortage had a strengthening effect on the bichromate market and supplies were reported to be moving well with prices very firm. *Potash bichromate* of standard brand was quoted at 12c. per lb. and the *soda* at 9@9½c. *Potassium carbonate* moved in a fair way and was firm, with the 96-98 per cent material offered at 6c. per lb. *Potassium permanganate* was advanced by the leading dealers to 17@18c. per lb., price according to quantity. *Sodium bicarbonate* moved in a routine way and was firm at 2¼c. per lb. *Sodium cyanide* was in fair demand and the imported 128 per cent material sold at 25c. per lb. *Sodium fluoride* was quiet at 10½c. per lb. *Zinc chloride* was available at 6½@7c. per lb. for the granular.

Linseed Oil and Turpentine

Linseed oil continued to move in a fair volume, but the price was considered high by some of the dealers. The boiled oil was quoted at the close of today's market at $1.07 per gal. in single-bbl. lots with similar quantities of the raw at $1.05. *Turpentine* was in a position similar to linseed oil and was believed to be too high priced. It was quoted today by the leading interests at $1.40 per gal. for single-bbl. lots.

The Iron and Steel Market

PITTSBURGH, Sept. 15, 1922.

Operations at the steel plants continue to increase. More than a score of steel works blast furnaces have resumed operations since the end of August, when the low point fell in pig iron and steel production. There has been very little increase in the supply of Connellsville coke. The chief factor has been heavier deliveries of union-mined coal to byproduct ovens at steel plants.

From the production of the thirty steel companies which make monthly returns to the American Iron and Steel Institute it may be computed that the industry as a whole produced ingots during August at the average rate of 30,000,000 tons a year, and an estimate may be made that the opening rate of the month was about 34,000,000 tons and the closing rate about 26,000,000 tons. The high point of the year was a 37,000,000-ton rate, reached late in June.

There has been a substantial gain in steel production from the low rate of a fortnight ago, but it is doubtful whether the higher rate of last June will be attained in the near future. Railroad congestion is becoming severe and it is possible that the present rate of coal shipping cannot be maintained.

There are more cases of car shortages at steel plants. More than half the plants requiring box cars are short. A practically new development, of the past week, is the placing of embargoes against shipments to various points, consumers thus being shut off from the receipt of steel.

The steel market is now almost entirely one of early deliveries. Jobbers and manufacturing consumers exhibit little interest in late deliveries in December or the first quarter of the new year, and any earlier delivery is more or less a special delivery, involving a premium.

Steel Prices

It is understood in the trade that Carnegie prices are still 1.90c. on bars and 2c. on shapes and plates, deliveries being far in the future and by no means guaranteed. The common price among independents is 2.25c. for all three products, but a few are taking orders from regular customers at 2.15c. in the case of bars.

In sheets there are no sellers left on the 3.35c. basis except the Steel Corporation, the two most conservative independents having advanced to a 3.50c. basis. Reports are of sales at 3.75c., but such sales are probably of quite small volume, since at 3.50c. one can obtain delivery in a few weeks.

All the independent wire mills have advanced their prices $3 a ton, to 2.50c. for plain wire and $2.75 for nails. The prices are readily obtained by such mills as can make early deliveries. One mill is able to ship nails in a fortnight.

Under date of Sept. 13 the Reading Iron Co. has advanced wrought iron pipe 5½ points, or about $11 a ton, and it is expected other makers will follow. This is the second advance in a short time. The new basing discount is 34 per cent.

Pig Iron Uncertain

Question is being raised whether pig iron can hold its recently attained levels, and predictions that further advances will occur, to $40 or $50, have become quite unpopular. The demand for foundry iron, which has been quotable at $35@$36, valley basis, on the strength of some resales and some purchases of Buffalo iron, has been decidedly light. In the case of basic iron, the $30 valley price recently quoted as the nominal market is considered rather more than consumers are able to pay. It is stated positively that a steel works did buy 2,000 tons a few days ago at $32.50 valley, the iron coming from a speculative interest that had held it since early in the year, but on the other hand it is related that $30 has been quoted since then without finding any taker.

Production of merchant pig iron is very light and is increasing but little if at all. The blast-furnace resumptions have been almost wholly of steel works stacks, resulting from better coal deliveries to their attendant byproduct ovens. Offerings of Connellsville coke have increased a trifle, but are still very meager, and the chief dependence of merchant furnaces normally is on Connellsville coke or surplus coke from byproduct plants of steel interests. Connellsville furnace coke is quotable at $11@$11.50, but the market is made almost wholly by purchases of water-gas manufacturers, lime burners, brickyards, etc. Foundry coke is $12.50 @$13. For a fortnight car supplies in the Connellsville region have been no more than adequate, and in the past couple of days some really serious shortages have been reported. Nominally, the strike is still on in the region, but practically it is no longer of consequence, as increasing working forces and decreasing transportation facilities have now practically met.

Pittsburgh district steam coal has softened 25c. in the week, being now quotable at $4.25@$4.50. Connellsville steam coal is held at $4.25, but is not in favor in competition with Pittsburgh coal. Byproduct coal is $4.75@$5.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Phœnix Portland Cement Co., Real Estate Trust Bldg., Philadelphia, Pa., with cement mill at Nazareth, Pa., has taken title to a tract of property at North Birmingham, totaling about 70 acres, heretofore held by the Sloss-Sheffield Steel & Iron Co., as a site for a new plant. Plans are being completed and a portion of the primary equipment ordered. Work will be placed under way on the initial buildings at an early date. The mill will have a capacity of about 1,500,000 bbl. of cement per year, and is estimated to cost in excess of $2,000,000, complete. Lindley C. Morton is president, and R. S. Scott, consulting engineer in charge.

TARRANT CITY—The Alabama Byproducts Co. has construction in progress on an addition to its byproducts coke plant, to increase the capacity close to 50 per cent. The new units will be placed in service at the earliest date.

Arizona

AJO—The New Cornelia Co. is perfecting plans for the construction of a new flotation plant at its local copper properties. Work will be commenced at an early date.

Arkansas

VAN BUREN—The Van Buren Glass Co., recently organized, has arranged to take over the plant of the Arkansas Products Co., which has been closed for about a year past, and which previously was devoted to the manufacture of glass tubing, etc. The new owner will remodel and improve the works, and plans to resume production at an early date. A new line of glassware will be manufactured at the plant.

California

NEVADA CITY—W. F. Heffinger and A. A. Tibbe, both of Oakland, Calif., are organizing a company to manufacture oil products, with pine needle extraction the primary basis of production. Negotiations are under way with the Chamber of Commerce, Nevada City, for a site for the proposed new mill. A selection will be made at an early date, and plans prepared.

Florida

JACKSONVILLE—The Kreiss Process Products Co., recently organized with a capital of $750,000, to manufacture potassium phosphate, etc., has preliminary plans in progress for the erection of a local plant, to be equipped for a monthly output of about 4,000 tons. It is estimated to cost approximately $75,000, including equipment. E. R. Taber is president, and Charles N. Weishans, secretary and treasurer.

Georgia

MCINTYRE—The Walden & Massengill Co., recently organized to operate a kaolin mine in this section, has tentative plans under consideration for the installation of a refining plant in the near future. H. A. Walden and C. G. Messengill head the company.

ATLANTA—The I. V. Sutphin Paper Co. has preliminary plans under way for the rebuilding of the portion of its local building, recently damaged by fire.

SAVANNAH—The Western Paper Makers' Chemical Co., Kalamazoo, Mich., with branch plants at Pensacola and Jacksonville, Fla., is reported to be planning for the establishment of a new paper mill in the vicinity of Savannah, with adjoining works for resin refining. The company is capitalized at $1,000,000, and recently acquired the properties of the Grecian-American Turpentine Co. in this section.

Illinois

JOLIET—The Illinois Wall Paper Co., affiliated with the York Card & Paper Co., York, Pa., Robert D. McCoy, president, has excavations under way for the construction of a new 1-story plant on Logan St., to be 100x300 ft., and estimated to cost about $75,000. R. C. Hoen, National Bank Bldg., Joliet, is architect.

Indiana

CARBON—The Carbon Firebrick & Coal Co. has completed plans for the erection of an addition to its local firebrick and refractory plant, to cost about $130,000, including machinery. E. E. Dean is president.

JEFFERSONVILLE—The Falls City Hydraulic Brick Co. is perfecting plans for the immediate installation of new equipment at its plant. A new kiln will also be constructed. Robert Akers is superintendent.

Kansas

ELDORADO—The Lewis Co. has commenced the construction of a new gasoline absorption plant in the Molter district. The plant will be equipped to handle about 5,000,000 cu.ft. of gas per day, with output averaging from 1 to 3 gal. per 1,000 cu.ft.

Louisiana

ELIZABETH—The Calcasieu Paper Mfg. Co., recently organized with a capital of $250,000, has plans under way for the erection of a new mill on local site for the production of kraft paper. A plant unit will also be installed for the production of tissue paper, with initial output approximating 10 tons per day. The project will include a byproducts plant for the recovery of turpentine and resin. The works will cost close to $150,000. R. M. Hallowell is president.

KENTWOOD—The local Chamber of Commerce has negotiations under way for the establishment of a new paper mill. A company will be organized to operate the plant. C. A. Kent, Sr., president of the Chamber of Commerce, is interested in the project.

Maine

WOODLAND—The St. Croix Paper Co. is reported to be planning for the rebuilding of the portion of its mill at Woodland Junction, recently destroyed by fire with loss of about $40,000.

Massachusetts

LEE—The Mountain Mill Paper Co. has commenced the erection of an addition to its mill at East Lee, comprising a main 1-story building, 40x150 ft., estimated to cost close to $60,000. It is planned to install equipment at an early date.

Michigan

KALAMAZOO—The Council is having plans prepared for the construction of a new municipal gas works, comprising six buildings, estimated to cost close to $2,000,000, including machinery. Burns & McDonnell 402 Interstate Bldg., Kansas City, Mo., are engineers. C. L. Miller is city manager.

JACKSON—The J. & S. Plating Co. has arranged for the establishment of a new metal plating plant at 112 East Washington St., and plan to commence operations at an early date. George J. Sights is general manager.

MUSKEGON — The Campbell-Wyant-Cannon Foundry Co., operating a foundry at Muskegon Heights, has perfected plans for the establishment of a large foundry in Muskegon proper, and will commence production at an early date. It is expected to provide facilities to give employment to a working force of about 1,000 men during the next few months. Frank E. McKee is vice-president.

New Jersey

GLOUCESTER—The Hinde & Dauch Paper Co., manufacturer of corrugated paper products, will soon commence the erection of an addition to its local mill, 1-story, 60x140 ft., to be used for increased capacity in the taping, slitting and affiliated departments.

WHIPPANY—R. B. McEwan & Sons are arranging for the rebuilding of the portion of their local paperboard mill, destroyed by fire, Aug. 30, with loss estimated at about $25,000. The fire originated in the boiler plant.

New Mexico

HILLSBORO—The Bonanza Mine is planning for improvements in its milling plant, including repairs to machinery, new operating equipment, etc., and purposes to place the mill in service at an early date.

New York

BUFFALO—The Angola Tire & Rubber Co., 270 North Division St., has awarded a contract to John A. Zoll, 398 Bird Ave., for the erection of a 1-story addition to its plant, 30x80 ft.

TONAWANDA—The J. Spaulding & Sons Co., 484 Broome St., New York, manufacturer of fiber products, has commenced the erection of a new 1- and 2-story addition to its plant at Tonawanda, 60x200 ft. and 100x300 ft., respectively, for general increase in production. The structures will cost about $250,000, including machinery. George F. Hardy, 309 Broadway, New York, is engineer.

North Carolina

BADIN—The Tallahassee Power Co. is planning for the installation of additional equipment at its local aluminum refining plant.

FLETCHER—George C. Sheehan, Asheville, N. C., is organizing a company to construct and operate a local brick and clay products manufacturing plant. A site totaling over 75 acres of land, including extensive clay deposits, has been acquired. The initial works are estimated to cost about $60,000.

Ohio

AKRON—Fire, Sept. 5, destroyed the plant of the Leo Meyer Co., North and Furnace Sts., comprising a 2-story building, equipped for rubber reclaiming operations, with loss estimated in excess of $80,000, including machinery. It is said that the plant will be rebuilt.

MIDDLETOWN—The Gardner-Harvey Paper Co., has awarded a contract to the F. H. Vaughn Building Co., Hamilton, O., for the erection of a new 1-story and part basement plant addition, 200x400 ft., estimated to cost close to $150,000. The plant will be used primarily for the manufacture of boxboard specialties, with machinery installation estimated to cost in excess of $30,000. Thomas H. Scott, P. A. Sorg Bldg., Middletown, is architect. E. T. Gardner is president.

YOUNGSTOWN—The Youngstown Steel Co. will soon commence the erection of a new mechanically operated puddling plant. It is expected to have the mill ready for service early in the coming year.

Oklahoma

DEWAR—The United States Zinc Smelting Co. is planning for the rebuilding of the portion of its local mill, including crusher and mixer rooms recently destroyed by fire, with loss reported at about $17,000.

ADA—The Choctaw Cotton Oil Co. has acquired the cottonseed oil mills of the Osage Cotton Oil Co., consisting of a number of plants in Oklahoma, Louisiana, Arkansas and Florida. The new owner will make a number of improvements and extensions in a number of the mills. A total of 26 oil mills, 1 oil refinery and 1 lard compounding plant will be operated. J. F. Phillips is president, and P. A. Norris, general manager.

Oregon

SALEM—The Oregon Pulp & Paper Co. has awarded a general contract to C. Van Patten & Son, Salem, for the erection of a new plant unit, consisting of a 4-story, reinforced-concrete mill, 75x80 ft., estimated to cost about $300,000, including machinery Work will be placed under way at an early date. Knighton & Howell, United States Bank Bldg., Portland, are architects.

Pennsylvania

KITTANNING—The Kittanning Limestone Co. will soon take bids for the erection of a new 2-story building at its plant, 25x100 ft.

BRACKENRIDGE—The Atlantic Bottle Co., 90 West Broadway, New York, is said to have tentative plans under consideration for the rebuilding of the portion of its local glass manufacturing plant, destroyed by fire, Aug. 28, with loss estimated at about $300,000, including equipment.

YORK—The Gilbert Wall Paper Co., 728 Linden Ave., has plans under way for the

erection of a new plant at State St. and the Pennsylvania Railroad. J. A. Dempwolf, Casset Bldg., is architect. Paul J. Gilbert is president.

JOHNSONBURG—The Kistler Leather Co., 319 A St., Boston, Mass., has preliminary plans under consideration for the rebuilding of its local leather plant, known as the Rolfe Tannery, recently destroyed by fire, with loss estimated at about $150,000, including equipment.

PITTSBURGH—The Keystone Hair Insulating Co., 1243 Spring Garden Ave., will commence the immediate erection of a 1-story addition to its plant to cost about $42,000. Plans have been filed.

PHILADELPHIA—The Alemite Grease Cartridge Co., New York, represented by Charles M. Russell, 50 Church St., recently organized with a capital of $500,000, to manufacture lubricating greases, etc., has work under way on the establishment of a local plant, to be equipped for an initial capacity of about 20,000 grease-filled cartridges per day. The company is headed by C. E. Roberts and E. C. Landgren.

Tennessee

KNOXVILLE—The Knoxville Gas Co. is planning for extensions and improvements in its plant, including the installation of new equipment, estimated to cost close to $200,000. Alfred W. Young is president.

NASHVILLE—The Federal Chemical Co. is said to be planning for the rebuilding of the portion of its local acid works, destroyed by fire, Aug. 28, with loss estimated in excess of $150,000.

Texas

HOUSTON—C. A. Benton, 720 Oxford St., Monrose, Houston, has plans under way for the establishment of a new plant for the manufacture of pressed brick and other burned clay products. A list of equipment for installation will be arranged at an early date. A site for the plant has been selected.

ODESSA—A. P. Jordan, Winters, Tex., has organized a company to construct and operate a plant near Odessa for the manufacture of gypsum wall plaster. A complete refinery will be installed, with equipment to provide for an initial output of about 70 tons of plaster per day. A site for the mill, including raw material deposits adjoining, has been acquired. The plant is estimated to cost close to $40,000.

ROBSTOWN—W. C. Craig, Brownsville, Tex., is perfecting plans for the establishment of a local plant for the manufacture of brick and kindred burned clay products. A site has been secured.

WICHITA FALLS—The Empire Gas & Fuel Co., operated by the Cities Service Co., 60 Wall St., New York, has acquired the plants and oil properties of the Planet Petroleum Co., comprising more than 200 acres of land in the Electra and South Electra fields, for a consideration said to be about $3,000,000. The present leases and works have a daily output of about 5,000 bbl., and the new owner plans for enlargements and improvements.

Utah

SALT LAKE CITY—The Utah Oil Refinery Co., a subsidiary of the Midwest Refining Co., operated by the Standard Oil Co. of Indiana, Indianapolis, has plans in progress for the erection of an addition to its local oil-refining plant, to increase the capacity from 5,000 to 6,000 bbl. of crude oil per day. Two new crude oil stills, 3 high-pressure stills and auxiliary equipment will be installed.

Capital Increases, Etc.

THE CAYUGA ROCK SALT CO., Harrisburg, Pa., has filed notice of increase in capital from $500,000 to $800,000, for general expansion.

THE PITTSBURGH CRUCIBLE STEEL CO., Empire Bldg., Pittsburgh, Pa., has arranged for a bond issue of $150,000, for general operations, expansion, etc.

THE ATLANTIC DRIER & VARNISH CO., 57 Front St., New York, N. Y., manufacturer of varnishes and other paint products, has arranged for an issue of 5,000 shares of preferred stock and 10,000 shares of common stock, the proceeds to be used for general expansion.

ALEXANDER SEIDLER, INC., Newark, N. J., recently organized with a capital of $500,000, to manufacture chemicals, chemical by-products and affiliated specialties, will form a consolidation of the Alexander Seidler Co., 2 Orange St., and the Meyer & Carmody Import Co., both of Newark. The merged organization will extend its line of production. Alexander Seidler is president.

THE GENERAL PETROLEUM CORP., 71 Broadway, New York, is disposing of a note issue of $5,000,000, the proceeds to be used in part for general operations and proposed expansion.

THE TARX CHEMICAL CO., Chicago, Ill., has added 2,000 shares of stock, no par value, to its capitalization of $25,000, for proposed expansion.

THE ATLAS POWDER CO., 200 5th Ave., New York, has disposed of a stock issue of $4,080,000, a portion of the proceeds to be used for general operations, financing, etc.

THE EASTERN STRAWBOARD CO., Manchester, Conn., has filed notice of dissolution under state laws.

THE W. S. ALLING RUBBER CO., Norwich, Conn., has filed notice of increase in capital from $200,000 to $350,000.

Industrial Developments

GLASS—The Macbeth-Evans Glass Co., Pittsburgh, Pa., is arranging for the immediate resumption of production in the idle portion of its plant at Elwood, Ind., comprising one complete plant unit. This will place the works on a capacity basis for the first time in a number of months. Additions will be made to the working force.

The Wichita Falls Window Glass Co., Wichita Falls, Tex., is planning for the reopening of its plant early in October, following a curtailment of a number of months. It is said that the works will return to hand-blowing method of production, discarding the automatic process. Improvements will be made.

Glass factories at Millville, N. J., giving employment to a total of about 3,000 operatives, are delaying the resumption of production owing to difficulty in securing fuel. A number of plants purpose to install oil furnaces unless the situation improves.

Owing to car shortage, the Pennsylvania Glass Sand Co., has been compelled to curtail operations at its Keystone Works, Mapleton, Pa. It is expected to resume capacity production at an early date.

CERAMIC—The West Branch Brick Works, Renovo, Pa., has resumed production at its local plant, following a period of curtailment. It is expected to increase the present working force in the near future.

The Harbison-Walker Refractories Co., Pittsburgh, Pa., is maintaining capacity production at its plants at Flemington, Mill Hall and Farrandsville, Pa., with full working forces. An effort is being made, it is said, to obtain additional employees at the plants. Wages have been advanced from 6 to 10 cents an hour.

The Frankford Brick Co., Philadelphia, Pa., has adopted a production schedule of 35,000 bricks a day, and expects to maintain this basis for an indefinite period.

A number of brick plants in Eastern Carolina districts have been forced to suspend production on account of the railroad strike and fuel shortage.

LEATHER—The Standard Kid Co., Wilmington, Del., specializing in the manufacture of glazed kid, has adopted a production schedule of about 80 per cent of capacity, and has sufficient orders on hand to maintain this basis for a number of months to come.

Hide tackers at the plant of the A. C. Lawrence Leather Co., Peabody, Mass., have made a wage demand from 11½ to 12½ cents per hide. The men have been averaging from $35 to $44 a week, and ask for $50 average per week.

The New Castle Leather Co., Wilmington, Del., is operating at about 75 per cent of full capacity, and will maintain this schedule for an indefinite period.

The Beadenkopf Leather Co., Wilmington, Del., has resumed operations at its local plants, and plans to increase the present production schedule in the near future.

Robert Foerderer, Inc., Philadelphia, Pa., manufacturer of patent leather, has adopted a capacity production basis at its tannery. The plant was forced to curtail recently due to a shortage of raw skins.

IRON AND STEEL—The Replogle Steel Co., Dover, N. J., is arranging to blow in another blast furnace at its Wharton plant. Wages have recently been advanced 5 cents an hour at the mills. The iron ore properties of the company at Mount Hope have been reopened, giving employment to about 400 men.

The Bethlehem Steel Co., has blown in another furnace at its plant at Steelton, Pa. An additional battery of coke ovens has also been started.

The Lukens Steel Co. is maintaining active production at its Coatesville, Pa., plant, used for the manufacture of steel sheets, giving employment to close to 3,000 men. Wages have been advanced from 25 to 30 cents an hour, effective Sept. 15.

The Shenango Furnace Co., Sharpsville, Pa., has blown in its local blast furnace, following a shut-down for about 5 weeks.

The Valley Mould & Iron Co., Youngstown, O., has resumed operations at its plant, following a recent curtailment due to coal and coke shortage.

The American Rolling Mill Co., Middletown, O., is maintaining active production at its plant, giving employment to a full working force in the majority of departments. Wages of laborers have been advanced 6 cents an hour, and proportionate increases have been made in the wages of other operatives. Salaried employees have been granted a 10 per cent advance.

The Gulf States Steel Co., Birmingham, Ala., has adopted a double working shift at its 13-in. mill at the Gadsden, Ala., steel works. The 20-in. mill has recently been placed in operation for the first time since 1920.

The Glasgow Iron Co., Pottstown, Pa., is running full at its local mills, and has advanced the puddling rate from $7 to $8 a ton. Laborers have been granted an increase of from 27½ to 30 cents an hour.

The Colorado Fuel & Iron Co., Pueblo, Colo., has resumed operations in all departments with the exception of the rail mill, following a curtailment for a number of weeks. Wages of all classes of employees at the plant have been increased.

MISCELLANEOUS—The Bethlehem Spark Plug Co., Bethlehem, Pa., manufacturer of porcelain spark plugs, is operating its plant at capacity, with two departments working on a 14-hour day basis.

The Electric Hose & Rubber Co., Wilmington, Del., manufacturer of heavy rubber products, has advanced production to include a night shift in addition to regular day operation. Additional operatives are being employed.

The United States Industrial Alcohol Co., New York, has advanced production to a capacity schedule at its three plants at New Orleans, La., which have been running on a half-time basis for a number of months past. Employment will be given to about 500 men.

Owing to the high cost of coal, ranging from a former basis of $4 a ton to a present rate of $11 a ton, the Durex Chemical Co., Sweetwater, Tex., has closed down its local plant, used for the manufacture of barium compounds, for an indefinite period.

The Traveler Rubber Co., Bethlehem, Pa., has adopted an operating schedule of 450 automobile tires a day, as compared with about 75 tires daily at this time last year. The plant is giving employment to about 160 men, and has orders on hand to insure the present basis of production for a number of months to come.

The Exeloid Co., Stroudsburg, Pa., manufacturer of celluloid toys and kindred products, is planning for the reopening of its local plant, following a shut down for some time past.

New Companies

THE BELLBY NATURAL GASOLINE CO., Wichita Falls, Tex., has been incorporated with a capital of $150,000, to operate a gasoline refining plant. The incorporators are J. F. Darby, O. J. McKnight and W. K. Campbell, all of Wichita Falls.

THE TRINITY PAPER MILLS CORP., care of Boyce & Magee, Dover, Del., representatives, has been incorporated under state laws with a capital of $6,000,000, to manufacture paper and pulp products.

THE VELVETONE PRODUCTS CORP., New York, N. Y., care of J. J. Ryan, 355 East 149th St., New York, representative, has been incorporated with a capital of $10,000, to manufacture polishes, etc. The incorporators are J. and D. S. Rouse, and S. K. Haines.

THE ARKANSAS HOMESTEAD OIL CO., Fort Smith, Ark., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are Stephen Gilbert, Charles Clark and Hugh Johnson, all of Fort Smith.

THE GEES-HAMMOND CO., Springfield, Mo., has been incorporated with a capital of $100,000, to manufacture soaps and kindred products. The incorporators are John J. Gees and J. M. Hammond, both of Springfield.

THE SUPERIOR MAGNESITE PRODUCTS CO., Escanaba, Mich., has been incorporated with a capital of $25,000, to manufacture magne-

site specialties. The incorporators are P. L. Sullivan, E. W. Sivertsen and W. J. Clark, all of Escanaba.

THE R. E. CARPENTER CO., Henry St., Elizabeth, N. J., has been incorporated with a capital of $50,000, to manufacture chemical products. The incorporators are Stephen France, A. Vance Pierson and William R. Morris, all of Elizabeth.

THE STANDARD ENAMELING & MFG. CO., Camden, N. J., care of A. Moulton McNutt, 207 Market St., representative, has been incorporated with a capital of $125,000, to manufacture enameled products. The incorporators are Orlando S. Watts, John Predow and Morris Redi, all of Camden.

M. L. ULLMAN, INC., New York, N. Y., care of Sigmund Honig, 799 Broadway, representative, has been incorporated with a capital of $20,000, to manufacture chemicals and affiliated products. The incorporators are C. H. Halper, L. Arnoff and M. L. Ullman.

THE FIBRE PRODUCTS CO., Boston, Mass., has been incorporated with a capital of $100,000, to manufacture fiber goods. Arthur N. Rice, 4 Liberty Square, Boston, is president and treasurer.

THE ARLINGTON PAINT & VARNISH CORP., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $7,500,000 to manufacture paints, varnishes, stains, etc.

THE CALDWELL OIL & REFINING CO., Louisville, Ky., has been incorporated with a nominal capital of $5,000, to manufacture refined petroleum products. The incorporators are Farley M. Caldwell, William Yentch and R. Sterling Sanford, all of Louisville.

THE COLUMBIA BRICK CO., East Orange, N. J., has been incorporated with a capital of 5,000 shares of stock, no par value, to manufacture brick and kindred burned clay products. The incorporators are Richard and Daniel Reagan, Washington St., East Orange.

THE PROGRESSIVE FOUNDRY CO., Rochester, N. Y., care of Crittenden & Crittenden, Powers Bldg., representative, has been incorporated with a capital of $100,000, to manufacture iron, steel and other metal castings. The incorporators are P. Bittner, C. Bennett, and C. Hobbing.

THE EUREKA CHEMICAL CO., Boston, Mass., has filed notice of organization to manufacture chemicals and chemical byproducts. The company is headed by Vincent Ambrosiano, 104 London St., East Boston.

THE KLEN-ZIT MFG. CO., Portland, Me., has been incorporated with a capital of $50,000, to manufacture chemical specialties. E. Sturdivant is president, and H. P. Sweetser, Portland, treasurer. The last noted represents the company.

THE OTSTOT DEVELOPMENT CO., Blackwell, Okla., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated with a capital of $250,000, under Delaware laws, to manufacture petrcleum products. The incorporators are R. Otstot, Edward Shaft, Blackwell; and T. K. Vance, Enid, Okla.

THE HOOSIER FERTILIZER CO., 1400 North Halsted St., Chicago, Ill., has been incorporated with a capital of $40,000, to manufacture fertilizer products. The incorporators are Samuel L. Sarnatzky and Barnard Margolis.

THE MILNE FOUNDRY CO., Schenectady, N. Y., care of L. W. Block, Albany, N. Y., representative, has been incorporated with a capital of $100,000, to manufacture iron, steel and other metal castings. The incorporators are W. H. Milne, J. E. Laurie and G. C. Ratchford, all of Schenectady.

THE ORRITE CO., Nashville, Tenn., has been incorporated with a capital of $200,000, to manufacture composition stone and other composition products. The incorporators are W. H. Millard, Arthur W. Vantrease and King Sparks, all of Nashville.

THE SALEM FIBRE PRODUCTS CO., Salem, Mass., has been incorporated with a capital of $25,000, to manufacture fiber specialties. Everett B. Cook, Salem, is president; and Jennie O. Cook, Beverly, Mass., treasurer. The last noted represents the company.

THE GYPSUM ENGINEERING & MFG. CO., Room 717, 111 West Washington St., Chicago, Ill., has been organized under state laws to manufacture gypsum specialties, and magnesite byproducts. The incorporators are Willard L. King, Sanson Gusdorf, and Robert I. Rheinstrom.

THE STICKEL-HEFTER YEAST CO., Bedford Park, N. J., has been incorporated with a capital of $500,000, to manufacture yeast and kindred products. The incorporators are C. H. Hefter, Herman Abbenseth and John Stickel, Mill St. and Willett Ave., Bedford Park. The last noted represents the company.

DYES & CHEMICALS, INC., Montclair, N. J., has been incorporated with a capital of $150,000, to manufacture chemicals, chemical byproducts, dyes, etc. The incorporators are Lennox C. Brennan, William H. Orr and Francis Earle, 120 Highland Ave., Montclair. The last noted represents the company.

THE ORIOLE PETROLEUM CORP., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated with a capital of $100,000, under Delaware laws, to manufacture oil products.

THE HOFFMAN CHEMICAL CO., Brooklyn, N. Y., care of J. A. McNamara, 165 Broadway, New York, representative, has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are D. J. Murphy, J. M. McNamara and T. P. Mackey.

THE TARVER BROTHERS PETROLEUM CORP., Houston, Tex., has been incorporated with a capital of $100,000, to manufacture oil products. The incorporators are G. B. Outlaw, J. B. Warren, and J. D. Tarver, all of Houston.

THE OPEN-HEARTH FIREBRICK CO., care of the Delaware Incorporating Co., Wilmington, Del., representative, has been incorporated under state laws with a capital of $5,500,000, to manufacture firebrick and other refractory products.

THE WATERMAN OIL CO., 2nd St., Waterman, Ill., has been incorporated with a capital of $5,000, to manufacture oil products. The incorporators are C. W. Smith, H. Roberts and A. R. Wollenweber, all of Waterman.

THE WILKINSON GUANO CO., Spartansburg, S. C., has been incorporated with a capital of $25,000, to manufacture fertilizer products. Floyd T. Smith is president; and J. C. Wilkinson, vice-president, both of Spartansburg.

THE SERVO SALES CORP., Brooklyn, N. Y., care of J. A. McNamara, 165 Broadway, New York, representative, has been incorporated with a capital of $50,000, to manufacture chemical products. The incorporators are D. J. Murphy and T. P. Mackey.

THE CODDE BRASS & ALUMINUM CO., 1006-7 Hammond Bldg., Detroit, Mich., has been incorporated with a capital of $30,000, to manufacture brass, aluminum, bronze and other metal products. The incorporators are Mayer C. Brown and Harry A. Codde.

THE TEX PRODUCTS, INC., Brooklyn, N. Y., care of S. Rosenfeld, 808 Broadway, Brooklyn, representative, has been incorporated with a capital of $50,000, to manufacture cleansing powders, chemical specialties, etc. The incorporators are H. Pearlman, and H. F. Pearsall.

THE EASTLAND PIONEER OIL REFINING CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $1,000,000, to manufacture refined petroleum products.

THE UNITED STATES LEAD CO., 237 Baldwin Ave., Jersey City, N. J., has filed notice of organization to manufacture white lead and kindred products. Alfred J. Parker heads the company.

Industrial Notes

THE SCHEID ENGINEERING CORP., 90 West St., New York City, has been appointed metropolitan and export representative for the Franklin Moore Co., Winsted, Conn., manufacturer of material-handling machinery for industrial plants.

THE NATIONAL CARBON CO., in order to reduce the time required for handling small and other emergency requirements of carbon brushes and to give better service to its customers, has established two finishing plants, one located at 337 East 41st St., New York, and the other at 560 West Congress St., Chicago. These supplement the emergency department maintained for some time at the Cleveland factory. Both of these plants carry complete stocks of all leading grades of Columbia carbon, graphite and metal graphite brushes, and are prepared to furnish all sizes equipped with standard types of shunt connections, or other special methods of finishing. The same standards of workmanship and the same close attention to and inspection of detail as obtained in the larger brush plants of the company are strictly observed in these small plants. Necessarily the capacity of these plants is limited and it is the desire of the company that, where delivery conditions will permit, orders for material of this kind be forwarded to Cleveland, O. as in the past. However, on breakdown jobs and other requirements of an emergency nature, the users of brushes in the surrounding territories should avail themselves of the special facilities at New York, Cleveland and Chicago, and should send their orders to the nearest plant.

On Aug. 1 the SCHAEFFER & BUDENBERG MFG. CO. acquired the business and good will of the American Steam Gauge & Valve Mfg. Co. of Boston, Mass., and is operating it as a division of its own business, with headquarters and sales department located at 338 Berry St., Brooklyn, N. Y.

THE NELSON VALVE CO. announces that its office at 90 West St., New York City, is now under the management of Walter S. Dickson, who is in charge of the New York district and export departments.

THE CHICAGO FLEXIBLE SHAFT CO., Chicago, Ill., announces that the address of its New York office, of Stewart industrial furnaces, which has been located at 350 Broadway since it was established early in 1920, has been changed to 16 Reade St. The office, as before, is in charge of J. W. Lazear.

THE CLEVELAND COOPERAGE CO., Cleveland, O., has taken over the manufacture and sale of a rubber-lined barrel originally invented by James H. Gravell, president of the American Chemical Paint Co., and used in carrying the production of that company. The new Lastik barrel is used for the transportation of acids, extracts, tinctures, oils, varnishes and chemicals.

THE DARCO SALES CORP. has announced the appointment of Jayne & Sidebottom, Inc., 17 Battery Place, N. Y., as its sole selling agent in the New York metropolitan district and the State of New Jersey, for Darco decolorizing carbons.

THE PENNSYLVANIA PUMP & COMPRESSOR CO., Easton, Pa., announces that James A. Beaubien, formerly vice-president and general manager of the Weber Subterranean Pump Co., is now manager of its New York office at 30 Church St.

THE HEYDEN CHEMICAL CO. of New York City has elected Bernard R. Armour president. F. H. Chamberlain, formerly president, will continue as chairman of the board of directors. George L. Armour has been elected treasurer, and James Branegan has been re-elected vice-president. George F. Lewis will retain his connection with the company for the present as secretary. William Weckman has been elected assistant secretary.

THE FOAMITE-CHILDS CORP. is the name of the company representing the consolidation of the Foamite Firefoam Co. of New York and the O. J. Childs Co., Inc., Utica, N. Y., both of which handle complete fire-protection service. The following officers were elected: W. J. Childs, president; F. M. Watters, vice-president; E. Janeway, secretary, and F. J. Maginniss, treasurer. James C. Patterson will continue as a director in full charge of sales. It has been announced that there will be no change in the sales policies of the consolidating companies. Executive offices are located at Utica, N. Y.

THE WALKER CHEMICAL CO. and the SELDEN CO. of Pittsburgh, Pa., have been consolidated into one concern and the business of both companies will be carried on in the name of the Selden Co. No change of any kind has been made in either the personnel or management.

Coming Meetings and Events

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Montreal, Sept. 21, 22 and 23. Headquarters will be at the Windsor Hotel.

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS will hold its 126th meeting at San Francisco, Calif., Sept. 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY has discontinued meetings for the summer, but will resume them in October.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

The New Tariff Law of the Land

REVISING the tariff has been such a slow and disgusting process that most of us are glad it is over and that the Fordney-McCumber act has at last found its place on the statute books. The uncertainties that for twenty months have attended the maneuvering of the politicians and lobbyists have had a most depressing influence on business and, to a lesser extent, will continue to have until the courts have given final interpretation to the involved construction of many of the new tariff schedules. As for the law itself there is but little good to be said about it. Probably it is too early to pass judgment on its effect on industry, but after a brief study of its make-up we would hesitate to predict for it the quality of permanency which in the early stages of its preparation was supposed to be its distinguishing characteristic.

If there is any single feature in the new law, however, that marks an advance in tariff legislation, it is the provision for flexible administration. When Congress surrendered to the President the authority to raise or lower duties in order to meet changing conditions of competition, the first step was taken toward divorcing the tariff from politics. That beginning carried to its logical conclusion may some day mean a tariff controlled and administered by an impartial, non-political agency.

The dye and chemical provisions are no more satisfactory to our industries than is the law itself. It would seem that the dye embargo is a dead issue. On different occasions the Ways and Means Committee, the Finance Committee and the joint conference have each succeeded in inserting the embargo feature in the bill only to see it rejected subsequently by a majority vote of the Senate or House. Its last appearance in the original report of the conferees was something of a surprise to the industry, but is now generally regarded as a clever political move on the part of one of the embargo's most bitter opponents. The net effect as far as the industry is concerned is a much lower duty than had been approved by the Senate under the Bursum amendment.

But the sorest loss of all arises from the fact that the provision for synthetic organic chemicals other than from coal tar somehow got lost in the shuffle and emerged from the conference with a paltry 25 per cent ad valorem—and on foreign valuation at that. This strikes at the very root of our fine chemical industry and efforts are already under way to remedy the situation. It is our sincere hope that they will be successful, but from experience and some little knowledge of the workings of that inexorable body in Washington, we can scarcely regard the outlook as promising. For our own part we are inclined to believe that the chemical industry should make the best of a sorry situation. We should forget about the tariff and get down to work building an industry on that solid foundation of research and technology which will not be swept away by the changing tides of politics.

The Chemical Industry And Its Exposition

WORSE than the confusion of tongues at Babel is the diversity of criticism current for the past two weeks regarding the Chemical Exposition and its management. Most of the talk is beside the point because it deals with numerous non-essentials that are a by-product of any controversy.

The elements of the situation are these: We have an exposition managed by a company that is in that business. The show is conducted for profit. Naturally there has been some dissatisfaction with the service rendered to exhibitors. It seems inevitable. The essence of the criticism is that the exposition management makes too great a profit; that it has departed from the ideals of the founders; and that exhibitors have no voice in many features of the show affecting their personal interests. More concretely, dissatisfaction has found expression in the proposal to organize and run another exposition.

Without launching into a long discussion of the whole subject, it can be set down as final that the chemical industry does not want and will not support two expositions. An attempt to put them on will result in disaster for both and perhaps final abandonment of any show. In our judgment the present management, with its experienced organization, offers the most practical means of continuing the exposition as long and as frequently as the industry wants it. If its methods and ideals are not agreeable to some of the exhibitors, an attempt should be made to change them, rather than to launch a new exposition. The management has repeatedly expressed not only its willingness, but its desire, to meet exhibitors' wishes as far as possible.

The crux of the whole matter is the necessity of having but one exposition, and the thing for exhibitors to determine is the most practical means of attaining that end. The expense of exhibiting at one show will be quite as great as at another if both are free to the public; and the advantages of a co-operative show are more imaginary than real, if we may accept the opinion of those who have tried both. Co-operative exhibitors must be prepared to meet deficits as well as to share profits. In short, we are inclined to the view that dissatisfaction over costs and profits will not be diminished by supporting a new exposition on a co-operative basis.

Undoubtedly much of the present criticism would disappear if the exposition management had a closer con-

tact with its exhibitors. This is not impossible of accomplishment and perhaps some way can be found whereby the exhibitors can transmit their views and sentiments to the management, and through occasional conferences come to agreement on moot points. Every reasonable means of attaining this end should be exhausted before resorting to more drastic action.

The Riddle Of Corrosion

PROBABLY more than one philosophic Indian, during the course of the last 1,500 years, has looked with envy on the remarkable iron pillar at Delhi, and wondered how it continued standing through the ages, rustless, while his own iron tools and kettles, made of the same stuff and in the same way, wasted away during his lifetime. Apparently the same, yet somehow different.

That riddle is still unsolved. Science, during the last century, has invented many names to denote many facts and phenomena concerning rusting, but we still wonder why one lot of condenser tubes will stand almost indefinitely under sea water, while another batch from the same reliable maker—indistinguishable except for labels—will be perforated by pitting within a few months. Apparently the same, yet somehow different! The differences may be so obscure as to yet escape detection, or for that matter may even be too minute for observation by our present-day apparatus.

Much careful study has been given the corrosion problem—and not more than it deserves, since it undoubtedly costs the world billions of dollars annually to protect its metal and replace that which was not protected in time. Innumerable laboratory determinations have been made, measuring the amount of weight lost by a metal when exposed to certain more or less well-controlled circumstances. But the trouble is that the metal does not always waste away uniformly or at a constant rate—localized corrosion and corrosion products are often the most dangerous. Hence, thinking back, it has been agreed that a very important factor is the action of the metal immediately upon immersion; its future history is dependent upon whether the first products of corrosion stick to the metal and protect its foundation.

So far, so good! Given the undoubted fact that a surface film forms, everybody interested in corrosion ought to start studying surface films, and discover what kind of film will stick tightly to the metal and not split off when the temperature changes (or if torn off, will immediately re-form), what kind of a film will be so impervious to its surroundings that it will not continue to grow, nor be continually removed as fast as or faster than it forms. But it's not as easy as it sounds. These films, in the first place, may, and quite often are, perfectly colorless and transparent. A logical deduction from the ideas presented elsewhere in this issue by Dr. SAKLATWALLA is that they are often only a few molecules thick and far below the limits of our most powerful microscopes. Or if we lean toward LANGMUIR'S ideas, the metal is joined to its gaseous surroundings by the same kind of forces that hold chemical compounds together, and has no independent existence.

To study such stuff a new technique is needed. Some new instruments, employing vaguely known or undiscovered physical properties, will be necessary before one can study the nature of such diaphanous garments. Microchemistry and microphysics, of which we know only a smattering, will have to be extended to ultra-micro regions before the kind of atoms contained in these protective films and their spatial arrangements can be known.

It will be a safe prediction that many years will elapse before we shall be able to draw a correct space lattice of the surface film on freshly cut aluminum or iron. Even if they are so obviously different in construction as to indicate immediately why the former resists the corrosion of the atmosphere while the latter does not, we shall still have to discover the way to make iron or a simple alloy of iron automatically build up a coating of the desired type.

Empirical trials may hit upon that method before we know much more about the real mechanism of corrosion, just as we have discovered that copper-bearing steel is excellent metal for sheathing. Furthermore, we have given up the search for an absolutely incorrodible metal, or one which will resist equally all reagents, gaseous, liquid and solid. A certain amount of wastage will always occur, but it can be minimized by careful selection of metals based upon an intelligent interpretation of available data. First approximations in this respect can be now made for hitherto untried conditions by remembering that corrosion is a compound action, consisting first of the formation of a reaction product, and second the removal of this product. If the two rates can be determined in the laboratory and the first is more rapid than the second, the metal will have a fair chance to endure.

Wanted—An Immigration Policy

THE PRESENT 3 per cent immigration law, having outlived its usefulness, if it was ever to be commended at all, is destined to be followed by something else. Instead of a makeshift being put on the statute books as another experiment, a definite and intelligent immigration policy should be adopted, and legislation worked out accordingly.

Republics are said to be in the habit of doing things too late. They certainly are slow in recognizing new conditions such as require new policies and new legislation. The disposition is to assume that as we have got along all right so far we can peg along for a few years more.

It should be emphasized that new conditions exist, and the public should be told what changes have occurred. The prevalent view seems to be that the great new condition that exists is the one growing out of the war. That is a change in conditions abroad. We should like to point out that long antedating the war a change occurred in the United States, a very important one and one that must be considered in all its bearings or nothing like a proper immigration policy can be developed.

That change is in the opportunity the country offers the immigrant. We have been an independent country for fourteen decades. For a little more than half the time we offered great opportunities for the pioneer, the man who came here to act of his own initiative, to do something himself. The opening of the West and Northwest after the Civil War offered the last great opportunity of this sort. In the recent decades the chief attraction to the immigrant has been nothing more than a job in the mine or mill or perhaps at coke ovens. Of course in the earlier period some men came over merely to hold a job, and in the later period some have come

over to make a fortune, possibly as a fruit peddler or as a dealer in old clothes. In general, however, the distinction holds good.

That our immigration has not been as satisfactory in recent decades as formerly, from the viewpoint of the general good of the country, is very well recognized. The difference is often mentioned, but usually it is left to be assumed that the difference is chargeable against those who choose between coming to the United States and staying at home. The real difference, however, is due to changes that have occurred in the United States, and that fact should be the starting point for the development of an immigration policy. Realization of the fact will banish the notion that since we used to get along we ought to be able to continue getting along.

The ordinary habits of thought of the individual are not always logical. Conclusions parading as the result of logical thought are frequently the product of emotions. With collective thought or conclusions the divergences are still more common. As a people we should decide upon certain definite premises and then seek the answer. Do we want immigration? For what purpose do we want it? What kind of immigration do we want to meet that purpose? How shall we obtain it? How shall we handle it when it comes?

If we settle these questions step by step, we shall accomplish intelligent results. If we slur them over, we shall have simply a hodgepodge debate in Congress with makeshift legislation calculated to get votes rather than good immigrants.

To illustrate: There are those who do not want any immigration. They should be yielded to or silenced at the outset. They cannot be expected to give wise counsel when we are attempting to decide how we shall obtain immigration.

Black Fractures in Carbon Tool Steels

IN OUR ISSUE for August 9 we published a short article by Mr. GREEN on "Black Fractures in Carbon Tool Steels." Since then many of our friends have been good enough to point out that the occurrence is a simple case of graphitization. Steel makers have apparently seen the structure before—sometimes oftener than they wish—but have said very little about it in print.

On page 650 of the present issue we publish the results of a brief supplementary study of Mr. GREEN'S steel by Messrs. RAWDON and EPSTEIN of the Bureau of Standards. A careful study of the two papers will doubtless reveal the fact that the case is not so simple as it appears.

In the first place, silicon—which all authorities agree is the thing that accelerates graphitization—is uniform and far below the danger point (0.10 per cent) in both light and dark zones. Second, why should there be such a pronounced and regular outline to the graphitized areas (suggesting the outline of the ingot or the roll-passes) and yet a pencil of ungraphitized metal occupy the very axis? Third, the sharp line of demarcation between structures is very peculiar. Fourth, the ease with which the graphite carbon is redissolved upon annealing even for a short period, as pointed out by RAWDON and EPSTEIN, is surprising, in comparison with the rather stable conditions obtaining in other portions of the bar having a light fracture but also containing considerable graphite. Fifth, long heating at a rolling temperature seems to be one of the works conditions favoring graphitization; but if this temperature is in the austenitic area of the equilibrium diagram, the carbon or carbide would be uniformly distributed in solid solution with no tendency to segregate.

From a commercial point of view these questions have real importance, for we are assured that sometimes steel with black fractures arrives by the ton, instead of by the bar, as found by Mr. GREEN. Consequently the reasons for its occurrence should be determined with the greatest possible precision. From a theoretical point of view it has interest almost as great. We find it difficult to accept the dictum, "Graphite is the stable form of carbon," as a self-evident and sufficient premise from which to explain all the facts surrounding the graphitization of cementite—either in tool steel, gray cast iron or malleable iron. Since all the irons and steels which graphitize easily contain important amounts of many elements other than iron and carbon, it does not seem apparent on the face of it that the iron-cementite system is doomed forever as "metastable."

The Proper Training Of a Chemical Engineer

A SUBSCRIBER whose comments are always illuminating to us and who, although a manufacturer of heavy chemicals, is without professional training and has not been in his present occupation more than a few years, writes us about the way he is training a student of chemistry in whom he is interested. We may say that in the short time of his engagement in chemical industry he has insisted upon being taught the nature of every technical problem in his work, that he has accomplished large savings of wastes and that he has been successful. It may be that his previous experience in an industry that is chemical, although he did not know it, has opened his mind. Here is what he says:

"I have a young man associated with me who is in his first year of college. He is taking chemical engineering and will spend three months each year at my plant. This year he is helping the lead burner and will get a thorough knowledge of lead burning. Next summer he will unload hopper cars, heave coal, fire boilers under the instruction of our stationary engineer. Three months of that will give him a fairly good working knowledge of the process of the boiler, its economy and utilities.

"The next vacation he will spend in the plant operating digesters and other chemical equipment, then, when he graduates, I will take him into the office and let him handle shipping, accounting, telephone work, payrolls—in fact, all the various things that go to make up a man's commercial education. *After that* he will be permitted to go into the laboratory and start to work on the things for which he was educated. He will then realize that making mud pies in a beaker in ounce quantities is quite different from making them in 100-ton lots in great steel retorts and digesters. He will also realize that it takes labor to produce chemicals commercially. If he does not make a good successful chemical engineer of himself with that opportunity, I shall give up and admit I don't know how to train boys."

If he does not succeed with the young man in question, it will be the fault of the young one, and not the old. It is well for every student to bear in mind that business, properly administered, is one of the most difficult of arts and that he can never be fully in the game of manufacturing unless he has a clear sense of business.

Chemists in Public Life

To the Editor of Chemical & Metallurgical Engineering

SIR:—Randolph Bolling in his letter appearing in your issue of Sept. 6, commenting on S. L. Redman's communication concerning "Chemists in Public Life" seems to indicate the soul of a chemist in the statement, "We just want to be left alone."

A splendid isolation seemingly is the main desire of chemists. They prefer routine. Anyone who has tried to get a rush test for control work in industrial processes can verify this tendency of chemists. A laboratorian simply can't be rushed. Possibly $1,000 may be at stake—he should worry, just so long as his 2 cents worth of this and 1 cent worth of that react on a sample that costs nothing according to all the rules and the classics.

Chemists assuredly must be in public life. They should live, not as hermits, as alchemists, but as men. All the angles of modern industrialism demand analysis, and after analysis comes decision. Certainly analysis of all the facts is much more involved than a grouping of chemical elements, often sadly done empirically, and the man best equipped to make the analysis is a chemist who appreciates business. Public life is business, not politics, and most if not all our universities provide an elective if not compulsory course in "business" or "efficiency," in which a certain amount of vocational guidance is provided in the order of things. The chemist with the spirit of "we just want to be left alone" habitually neglects this offering. The great teacher on the order of things is commercial experience, and the wide-awake chemist, the real analyist, should welcome offerings of positions such as Mr. Redman mentions, and not desire to be a hermit, for hermits have been known to starve to death.

Proteins and the Theory of Colloidal Behavior

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of Aug. 23 there appears a review by Jerome Alexander of Loeb's excellent book "Proteins and the Theory of Colloidal Behavior" that appears to me very unfortunate because it may give those of your readers who have not seen Loeb's book the erroneous impression that his work is not fundamentally sound, whereas it is evident that Alexander has failed to grasp Loeb's ideas. For example, he regards Loeb's thesis as standing or falling with the assumption that gelatin is a definite chemical entity. On the contrary, Loeb's theory is quite independent of this assumption; it assumes only that a highly ionizable chloride of gelatin is formed when gelatin is brought into contact with an aqueous solution of hydrochloric acid, and this is substantiated quantitatively in so many different ways as to give it a place among the facts of physical chemistry. Whether or not Loeb's gelatin was a mixture of proteins of variable molecular weight has no bearing upon the fundamental conception.

Loeb, as well as Procter and Wilson, has proved that the equilibria of aqueous protein systems are determined by the Donnan equilibrium, and it seems significant that no other view has ever passed the stage of qualitative speculation. Alexander's reference to "the adsorption view" means nothing, since adsorption as something distinct from the equilibria described by Loeb has not been resolved into anything more than a vague conception, which I believe will prove to be nothing more than a flight of the imagination of those who have tried to dodge the mathematics of the Donnan equilibrium.

I regard Loeb's book as marking the greatest advance yet made in this field and recommend it unreservedly to all interested in the subject indicated by its title.

Modern Handling Methods in the Manufacture of Electrical Porcelain

To the Editor of Chemical & Metallurgical Engineering

SIR:—With reference to the article which appeared in *Chem. & Met.* for July 12, 1922, entitled "Modern Handling Methods in the Manufacture of Electrical Porcelain," I have read this article with much interest. An article in the May *Journal of the American Ceramic Society* dealing with the same subject has also been brought to my attention.

I have carefully read these articles and, while we manufacture strictly sanitary plumbing fixtures and do not manufacture anything in the electrical porcelain line, still such papers are of great interest to us. There are a number of methods used in the manufacture of electrical porcelain that can be adapted to the sanitary line. There is no question that the pottery industry has been the slowest in putting in modern labor-saving devices; but I believe that the time is rapidly coming when the pottery industry will learn that it is best for it to use labor-saving devices as used in other industries, where they have been found to pay for themselves many times over.

It is becoming more necessary every day that the manufacturer cut down his manufacturing expenses so that he will be able to manufacture his wares at a minimum cost. If it is ever expected to reduce costs to what they were 10 years ago, the only possible way to do this is by the economical operation of the factory and by every possible labor-saving device that is practical to put into service. The price of labor will not go back to what it was 10 years ago; and for that reason the only way to reduce and keep costs down is by the careful and close study of the operation of the factory.

It is by such papers, read before the American Ceramic Society and published in the technical journals, that we conceive ideas and suggestions; and from these develop practical operations that are of great benefit to the industries.

Eighth National Chemical Exposition

Report of the General Meetings and Technical Sessions, Including Symposia on the Paper Industry, Technical Photography, Ceramics and Standardization—Attitude of Anti-Saloon League Toward Manufacture and Sale of Industrial Alcohol

EDITORIAL STAFF REPORT

THE Eighth National Exposition of Chemical Industries, which was formally opened on Monday evening, Sept. 11, marked the return to Grand Central Palace after an enforced absence at the Armory last year.

Interest in the technical programs centered in the address of Wayne B. Wheeler, general counsel for the Anti-Saloon League, who spoke on "The Attitude of the Anti-Saloon League Toward Industrial Alcohol." Chemical manufacturers wanted to know just what this attitude is, and were particularly glad of an opportunity to have Mr. Wheeler express it. Mr. Wheeler was introduced by Dr. Charles H. Herty, who presided.

ADDRESS OF WAYNE B. WHEELER

The substance of his presentment was that the organization he represents is in largest possible sympathy with the alcohol industry in its industrial aspect, and with chemical industry at large. He said that the organization's slogan is that the more alcohol we can get into industry and the less we get into people the better it will be all around. He was very particular to emphasize the statement that the Anti-Saloon League is strongly and urgently in favor of the widest manufacture and use of industrial alcohol. Following this, he noted that the Anti-Saloon League and the producers of, dealers in and users of industrial alcohol thus had a common purpose, which he construed as not only the development and furtherance of the alcohol industry as applied to arts and manufactures, but also in the prevention of its use as a beverage. For instance, he said, "You have a common purpose with us in keeping this trade within the scope of its purpose." Again, "When people have a common purpose they should get along."

He called attention to the fact that the present regulations in regard to tax-free alcohol are fewer in number than before prohibition, and that, while only 2,000,000 gal. of tax-free alcohol was sold in 1906, there was 35,000,000 sold in 1919. "But, remember," he shouted, "the alcoholic is here with his thirst!" And he went on to say that, while some regulations to prevent its unholy quenching may be a little burdensome, no burdensome regulation would have the backing of the friends of the Eighteenth Amendment so long as it did not encourage drinking. The close of his speech centered more and more on the obligation to society of the tax-free alcohol and chemical industries to enforce the Volstead act (which he did not once refer to under this name) and the provisions of the Eighteenth Amendment. It was a shrewd speech that may be used as an argument in favor of any kind of restrictive legislation unless chemical industry will pay the price of dropping everything and starting on the hunt for bootleggers. "Some method is necessary," he said, "to check up where alcohol goes!"

THE REACTIONS TO MR. WHEELER'S SPEECH

After discussing the address with others who heard it we find that some thought that Mr. Wheeler had shown great growth in his concept of industrial alcohol and that the prohibition slogan, heard all too often, that "all alcohol is booze, anyway," is losing force with the chief representative of the Anti-Saloon League, the strongest organized prohibition society.

That the government, through the corruption of its enforcement agents, is failing to suppress the liquor traffic is a point which the speaker missed. We doubt if many unauthorized sales of alcohol are made in the first instance. We are convinced that all legitimate producers keep their accounts clean. The alcohol usually leaves the warehouse with a clean bill of health, duly attested by an authorized permit. That is all we can properly ask of the seller. Purchaser No. 1 may be wholly honest and hold the goods strictly to legal requirements, refusing to part with them save under proper authorization. By the time it reaches purchaser No. 2 the original seller has lost track of it. Purchaser No. 3 or No. 4 may and probably does show a duly certified authorization, but after he has had it he may turn the alcohol into potable liquor. Mr. Wheeler said (in the manuscript prepared for the press which we have before us): "The industry itself must take into account the fact that it is handling a commodity which is liable to produce great evil. It must help in the policing of the commodity—so as to prevent the evils which might otherwise follow." We fail to see how "the industry," which has none of the facilities of search enjoyed by the government, can find out what is done with the property of others, or even that it should if it could. The cheerful wholesale bootlegger who went to Canada with an authorized and approved certificate for the purchase of 250 cases of Scotch whiskey "for sacramental purposes" and got away with it into the United States represents the kind of leak which the industry cannot control.

Chemists, like clergymen and teachers, belong to the poorly paid professions, and few of them drink, for economic reasons, no matter what their opinions of the law may be. The real hindrance to enforcement lies in the fact that a great number of otherwise law-abiding citizens are so firmly set against the prohibition laws that they do not propose to observe them and are willing to take the consequence of their infringements if they are found out. The Haig & Haig distillery in Scotland, despite greatly restricted sales in Great Britain, owing to the tax of eight and five pence the bottle, declared a dividend of 18 per cent this last year, which would have been 34 per cent, as we recall it, but for the income tax. Its product comes here.

CHANGE IN PUBLIC OPINION NECESSARY FOR EFFECTIVE ENFORCEMENT

The real trouble lies in public opinion, which has not as yet matured to catch up with the law. The call for help from the industry by the Anti-Saloon League has been granted in many ways, but the demand that it shall aid in "policing" the sale of alcohol after it has left its control under government certification seems to us to be asking more than is fair.

The S.O.C.M.A. Meeting

Dr. Herty was again in evidence on Tuesday, for the afternoon session of that day was under the direction of the Synthetic Organic Chemical Manufacturers' Association of the United States. As president of that organization he dedicated the meeting to the purpose of convincing the public that synthetic organic chemicals included not only dyes but medicinals, perfume materials, photographic chemicals, explosives and a great many other products. The first speaker was Burton T. Bush, president of Antoine Chiris & Co., whose subject was "Synthetic Perfumes."

Synthetic Perfumes

Perfumery is an art and always will be, according to Mr. Bush. But just as the chemist has improved the work of the artist in other lines by giving him finer colors, purer oils and better paper, so the perfumer will be benefited by the contributions of this science. He will be given a wider range of materials with which to work. The odors of the lily of the valley, the lilac and other sweet-smelling flowers which are impossible to obtain by any known physical means have already been duplicated with a fair degree of success by the organic chemist, and many more are to come. Here, indeed, is a fertile field calling for the highest type of synthetic chemistry.

H. E. Howe spoke of chemistry as productive science. The fact that the volume of manufactures has increased four times since 1880 is due largely, in his opinion, to the two sciences of chemistry and physics, which through improvement in process and equipment have made this advance possible.

Synthetic Organic Medicinals

The session was concluded with an address by Dr. Frank R. Eldred, who took for his subject "Synthetic Organic Medicinals." "From the standpoint of health and happiness," he said, "there can be no more important application of organic chemistry than in the production of substances for the relief of suffering and the cure of disease. During the last few weeks the medical profession of the country has protested in no uncertain terms against the executive and legislative acts that threaten to wipe out all of the progress which we have made in the manufacture of synthetic organic medicinals since we were cut off from the former German source of supply during the war. We have just cause to be proud of the fact that the manufacture of every important medicinal product has now been established in the United States and that in quality these products are equal and in many cases superior to the German medicinals."

Peace-Time Uses for Poison Gas

Ellwood Hendrick was the genial chairman of a well-attended session on Tuesday evening. The first speaker to be introduced by him was Brigadier-General Amos A. Fries, chief of the Chemical Warfare Service, U. S. Army. The committee had asked General Fries to speak on the elimination of insect and other pests and he said he was inclined to believe that the latter category included the human pest, which "combines the deviltry of all other known pests." But speaking in a more serious vein, the General was able to show many important peace-time applications of the various toxic and tear gases developed during the war. Insect and animal extermination is one of these applications, so is mob control and the protection of life and property. The co-operative work of the Chemical Welfare Service and the Department of Commerce in studying the boll weevil problem of the South was cited as an example of a very practical application of our knowledge of poisonous compounds.

Another great economic problem to which some attention is being given is the control of the teredo and limmoria that destroy piling in sea water. The tremendous losses from these pests have already been partially stopped by the use of creosote, but it is the present belief that a poisonous compound of most specific action will soon be found.

The Chemical Warfare Service has worked with even greater success in destroying gophers, rats and other rodents so destructive to pastures and fields and which also carry fleas or other insects that may infect human beings with the bubonic plague. It is now engaged in a study with the Philippine authorities on the adaptation of poisonous compounds to the destruction of the locusts that cause great loss to crops in the Philippine Islands.

Replacing HCN in Ship Fumigation

An interesting development of recent months has been the help given the Public Health Service in preventing accidents in fumigating ships. It has been shown that cyanogen chloride, a war gas well known though not much used, is probably a better vermicide than hydrocyanic acid gas itself. It is a powerful tear gas in concentrations only one-eighth that which is dangerous, so that accidents are completely guarded against. No human will resist the blinding tears produced by this gas, even in concentrations too low to be dangerous, any longer than is absolutely necessary to get out of the way. This will not only make the fumigation of ships safe, but should lead to the extensive use of cyanogen chloride in the fumigation of houses, factories, etc., in place of more dangerous and less efficient germicides.

The Place of Research

General Fries took a strong stand on the question of continuing fundamental research along these lines. In this connection he said:

> The one place where America fell down in the war was in producing the special technical supplies needed in war, in time for general use. In making a fetish of practicability, we lost sight of the necessity for deep research. If we will only learn to apply continually the lesson that deep research alone will enable us in the future to maintain our place in the sun, the benefits of the war will in time outnumber the losses.

Chemistry Viewed by a Southerner

The chemical industry has a loyal and able friend in the person of United States Senator Joseph E. Ransdell of Louisiana. It is most significant that as a member of the political party opposed to the protective tariff Senator Ransdell has been a stanch supporter of high duties on all chemical products—believing, as he does, that these are "essential to the proper development and maintenance of industry in this country." His address is in part as follows:

> Chemical industry in the United States should be developed along the broadest and most comprehensive lines for three reasons:
>
> *A.* Chemistry is essential to the successful prosecution of practically all the arts and sciences. In fact, there is no industry of modern civilization which does not require the constant aid of chemistry to its successful application. Therefore, we cannot afford to be dependent upon the chemists of any other country, and should develop every branch of the art in America.

B. The wonderful advance in chemical inventions and discoveries during the past century warrant us in believing that innumerable things are still hidden which will respond to intelligent, persistent effort on the part of chemists. Many of the diseases of man have been greatly ameliorated by chemical inventions and discoveries of recent years, such as aspirin, novocaine, salvarsan, etc. Why can we not expect the discovery of remedies that will give relief, and possibly effect cures, of such diseases as leprosy, cancer, pneumonia, tuberculosis, and others which afflict mankind so terribly?

C. It is unfortunate that nations of the world cannot remain at peace and ignore all preparations for war, but so long as this greatly desired end seems still in the distant future it behooves wise men to prepare for possible conflict. Most thinkers agree that the next war will be decided by chemical preparedness and foresight of the contestants, and that it will be a chemical war.

Possibilities in the South

In concluding his remarks the speaker reviewed the wonderful possibilities for chemical development in the "land of Dixie." After touching on such well-known industries as naval stores, phosphate rock and cottonseed oil, he spoke of the South's great wood pulp resources—as yet entirely undeveloped. He declared that more than enough wood is being wasted annually in the Southern States to supply the country's requirements for all kinds of paper.

The chemist and the chemical industry will find in the single state of Louisiana the following resources awaiting exploitation: Limestone, sulphur, lignite, clay, salt, oil, gas, cotton, wood and sugar. Surely these are the basic raw materials for a remarkable industrial development.

Governmental Co-operation With the Chemical Industries

C. R. DeLong, chief of the new Chemical Division in the Bureau of Foreign and Domestic Commerce, told how the Department of Commerce under Secretary Hoover's direction is becoming of real service to industry. The Chemical Division has for its particular field the general inorganic and organic chemicals, drugs and medicinal preparations, essential oils, perfumery and toilet preparations, pigments, paints and varnishes, fertilizers, explosives and pyrotechnics.

Some of the ways in which the division can be of additional service were outlined by Mr. DeLong as follows:

One of the important considerations is the means at the disposal of the bureau for the collection of information relating to foreign markets and industries. The department maintains twenty permanent offices in the important commercial centers of foreign countries. These offices are in charge of business men and economists acquainted with the commercial conditions surrounding the trade of each particular country. In addition, the department enjoys the co-operation of more than five hundred consular officers of the State Department. It is evident that these outposts of the government form a vast network of lines of communication on conditions in foreign countries. These representatives are constantly forwarding to the department at Washington inquiries for American goods and information on the competitive conditions which are met with in the individual countries of the world.

These representatives are in a position to advise American firms and manuafcturers as to agencies qualified to handle their products, as to the customs duties in force in the various countries, and as to other commercial regulations governing the sale of products in a particular country. This information on the world's markets, as received, is centralized in the various commodity and regional divisions of the Bureau of Foreign and Domestic Commerce. Here it is carefully studied and abstracted before being distributed to American industries. I believe that through these sources the Chemical Division will be able to assemble in Washington accurate and detailed information on the world's production and requirements for chemical products.

An Example—Caustic Soda in Germany

For the intelligent exportation of products it is necessary to keep in constant touch with changing conditions in the various markets of the world. For example, one would not ordinarily consider that there would be a market for American caustic soda in Germany, yet information reaching the Department of Commerce recently shows that there is an apparent shortage of caustic soda in this market, and that the demand is being largely supplied by the United States. As a matter of fact, approximately one-half of the caustic soda being imported by Germany is originating in this country. It can therefore be seen that with rapidly changing market conditions it is necessary to keep in constant touch with the various foreign markets if advantage is to be taken of these opportunities to sell American chemical products abroad.

In order that American firms interested in the exportation of chemical products may receive the benefit of confidential information on trade opportunities in foreign countries, the department maintains a classified list of American exporters and manufacturers, which is known as the "Exporters' Index." It should be emphasized that only American-owned firms interested primarily in the promotion and sale of products of domestic manufacture are eligible for listing on this "Index." A firm once listed on this "Index" is entitled to receive without charge confidential information on trade opportunities, such as financial references, reputation and standing of the firm making the inquiry, and other information helpful in the marketing of a particular commodity in a foreign country. Such firms are also entitled to receive, whenever requested, trade lists of firms capable of handling their products in foreign countries.

Statistical Information

The department can be of further aid to the chemical industry by supplying accurate and detailed statistics of the trade in chemical commodities, both in the United States and in foreign countries. It is essential to the intelligent conduct of business to know the extent of domestic and foreign markets, the degree to which these demands are being met, and the countries supplying the products. It is planned that the Chemical Division shall make a periodic analysis of domestic and foreign trade statistics so as to make available the extent of the world's trade in chemical products.

A recent gratifying advance has been made in this direction in the case of the statistics for sulphuric acid and acid phosphate produced by the fertilizer industry, through the co-operative efforts of the National Fertilizer Association and the Bureau of the Census. That bureau has recently published statements showing the production, stocks and sales of these products for the first 6 months of 1922 and, it is reported, will continue the collection of such statistics for 6-month periods. It is to be hoped that other branches of the chemical industry will see the advantage of such statistical information and that it will only be a short time until such statistics have been expanded to include other basic chemical commodities.

Co-operation of Industry Necessary

Trade associations and individual manufacturers should not wait for an invitation from the department to co-operate with the Chemical Division. The division is beginning to function, and has been established for the sole purpose of facilitating contact between the department and the chemical industry. It is earnestly desired that the industry will come to consider that the Chemical Division is a part of the industry itself and that it is the industry's means of contact with the government. We want trade associations and individual manufacturers in the chemical industry to feel that they can lay their problems before the division with the knowledge that their confidences will be respected and that we will endeavor to aid them in solving these problems by every means at the disposal of the department.

Carbon Dioxide in Food Products

P. W. Heath presented a paper on substituting carbon dioxide for air in food products. He said the

American people spends millions of dollars each year for bread, butter and ice cream, but doesn't know that 10 per cent of the volume of butter is air, and so, too, is 40 to 50 per cent of the volume of ice cream. What Mr. Heath recommends, and we are informed that he has patents which cover the process, is the provision of an atmosphere of CO_2 to cover the materials during the processes of kneading or agitation, in the place of air.

Carbon dioxide thus provides various distinct advantages. Milk fresh from the cow's udder contains 10 per cent CO_2 by volume. Half of this escapes shortly after milking, and a quarter more is lost through pasteurization. To bring milk back to an approximate normal condition he recommended the introduction of 22 oz. of CO_2 into every 1,000 gal. of milk. He said that CO_2 improves the flavor of foods when good raw materials are used, and that it stimulates the nerves of taste and smell.

He quoted a bulletin of the U. S. Department of Agriculture of 1916 on the progressive oxidation of cold storage butter. In this it is said that in 2½ days under storage at freezing point temperature, one-eighth of the imprisoned oxygen in butter becomes chemically combined and over three-quarters becomes combined in less than 2 months, and that the production of off flavors in cold storage butter is attributable to slow oxidation. CO_2 is approximately free from dust, whereas ordinary air contains from 20,000 to 40,000 visible dust particles per cubic inch, and CO_2 treatment tends to keep out molds, yeast and bacteria.

Ice cream beaten in air contains from 25 to several hundred per cent more bacteria than ice cream beaten in CO_2, while butter churned in the same medium shows a greater reduction.

The destructive effect of air on vitamins A and C was discussed, and many instances given to prove it. At the University of Minnesota, butter intended for animal feeding is kept under an atmosphere of CO_2 to conserve its vitamin A. He quoted McClendon of the University of Minnesota, who powdered orange juice by spraying it respectively into hot air and hot CO_2. Vitamin C was destroyed in the air-dried material while 1 oz. daily of the CO_2-dried juice protected 500 guinea pigs from scurvy. Three years ago, he said, only two Western cities were mixing foods in CO_2 instead of air. The practice is now becoming general.

Mr. Heath was introduced by E. D. Hale of the Liquid Carbonic Co. of Chicago.

Pulp and Paper Day

In arranging the program for the meeting of the Technical Association of the Pulp and Paper Industry held Wednesday afternoon, Sept. 13, a departure was made from the usual custom of having problems of pulp and paper technology presented by men in the industry. Instead, representatives of firms exhibiting equipment and devices used in this field were given an opportunity to explain these in detail.

A few of the papers dealt with equipment devised particularly for the paper industry, others covered the application of standard machines to specific problems in this field, while still another group treated such general subjects as draft gages, CO_2 recorders, steel belts, the V-notch meter, recording instruments and methods of testing for fastness to light.

Under the first classification came a paper by E. ... Trimbey, of the Trimbey Machine Works, describing a meter for use in conjunction with an automatic consistency regulator in controlling the proportional volumes of ground wood and sulphite pulp where these are used in the form of soft stock. Color and size may be regulated in the same manner. Individual drive with d.c. motors connected to a motor-generator set makes it possible to vary the proportion of any constituent, or to vary the speed of the whole system without changing the proportions by means of a rheostat on the generator.

Continuous Causticizing and Filtration

Among the more important papers stressing the application of standard equipment to paper mill problems were the following:

W. D. Mount, of the Glamorgan Pipe & Foundry Co. demonstrated the advantages of the continuous causticization process in which the lime moves in a cycle through the following equipment: continuous causticizer, decanter, rotary filter, rotary kiln, continuous lime slaker.

Further information on the use of rotary filters for handling sludge from the causticizing process was given by G. D. Dickey, of the Industrial Filtration Corporation, and H. A. Morrison, of the Oliver Continuous Filter Co. Mr. Dickey also pointed out the possibility of washing paper pulp efficiently on rotary hopper dewaterers. Other applications of the continuous drum filter were considered by Mr. Morrison, particularly for brown stock washing, thickening before bleaching and in place of deckers and save-alls.

Meeting of Technical Photographic and Microscopical Society

Members of the Technical Photographic and Microscopical Society were well satisfied with the interest aroused by the large collection of photographs which constituted the society's exhibit. There was a crowd before the remarkable aërial photographs of Manhattan Island constantly, while photographers and technical men who investigated more carefully the work displayed learned much of the latest developments of the art and its numerous applications to industry and scientific research. Consequently, it was an enthusiastic group of members who assembled on Thursday, Sept. 14, for the annual meeting of the society in the large conference room at the Grand Central Palace.

Reports were submitted by officers and committees. Officers for the coming year were elected as follows: President, Prof. E. M. Chamot, of Cornell University; vice-presidents, Bennett Grotta, Atlas Power Co., J. A. Lucas, McGraw-Hill Co., C. E. K. Mees, Eastman Kodak Co.; secretary-treasurer, T. J. Keenan, editor of *Paper*. A vote of thanks was extended to the retiring officers for their efforts in establishing the organization on a firm basis.

Technical Sessions

The program arranged for this meeting was extremely broad, ranging from the general subjects of pulp and paper manufacture to wireless telephony, the one common idea being the application of photography and microscopy to the various subjects. Unfortunately, the program was too long for the time available and several of the papers had to be read by title.

One of the most interesting subjects presented was Henry Green's discussion of "The Photomicroscopy of

DONT FAIL TO SEE ALL EXHIBITS
ON MAIN-MEZZANINE-THIRD and FOURTH FLOORS

Paint and Rubber Pigments." Mr. Green described the work of the New Jersey Zinc Co. in the development of zinc oxide and other pigments.

Photomicrography in Paper Research

"Photomicrography in Pulp and Paper Research Problems" was the title of a contribution from the Forest Products Laboratory prepared by Eloise Gerry and E. M. Diemer and read by the secretary. The paper was illustrated by numerous lantern slides showing the method of distinguishing woods by means of the microscope. Woods of similar appearance, such as red gum, birch and mahogany, are clearly distinguished by their totally different cellular structure under the microscope. It was interesting to observe the accuracy to which the mechanical strength of a wood can be estimated by a study of its structure. The samples observed under the microscope ranged from $\frac{1}{5{,}000}$ to $\frac{1}{800}$ in. in thickness.

Examples of the valuable information contributed by photomicrography in the manufacture of sulphite and soda pulp were shown, such as the marked effect of beating in the two processes. Another very practical application of the microscope was revealed by photographs showing the formation of the gum ducts in various conifers. By a careful study of this formation the cut can be made in such a way as to increase materially the yield of gum from the tree.

D. S. Mungillo presented a reel of motion pictures showing the methods used in a modern motion picture laboratory. This was followed by a brief description of modern machinery for developing, fixing, drying, printing and polishing.

The Motion Picture in Industry

The motion picture as an aid to industry was discussed by Alfred B. Hitchins, director of the Ansco Research Laboratory. Dr. Hitchins pointed out the fields in which the industrial movie is beginning to be utilized. It is of value for purely scientific problems in throwing light on the mechanism of natural phenomena, for the education of workers by reducing waste motion and eliminating unnecessary details in shop work and for sales demonstrations. Obviously, there is no more effective way of conveying a message than by a visual presentation of the story. It is possible to present any idea in an interesting and dramatic manner by using the artifices of photography for which the modern camera is equipped. By the use of the slow speed camera, motion can be synthesized, while for its analysis the ultra-rapid camera is admirably adapted.

An interesting example of the practical application of the motion picture to mechanical stoker construction was described. Motion pictures were made of the stoker in operation, the camera protected from the intense heat by a series of Pyrex glasses set in asbestos and cooled by a stream of air. One exposure was made every 8 seconds, with the result that so much additional light was thrown on the actual working of the machine that the engineers were able to design a much larger and better stoker.

John Mills, of the Western Electric Co., gave a talk on the principles of radio-telephony and the operation of the audion. Aside from the general interest in the subject matter, the audience was impressed with the facility with which a complex description of a highly theoretical subject was reduced to a very simple explanation by means of animated diagrams. It was a good example of the educational possibilities of motion pictures.

Clarence W. Gibbs described some of the most recent developments in motion picture photography and outlined some of the refinements and improvements that are being studied and tried.

A film entitled "Thirsty Cotton" was projected, accompanied by a talk by Thayer Francis of the Parks-Cramer Co. Some of the views showing the effect of moisture on the tensile strength of cotton and its appearance under the microscope were especially interesting.

Colors That Please Us

Giving a popular talk on synthetic organic chemistry before an audience that included several well-known dye chemists as well as a number of individuals who wandered in because someone gave them tickets is obviously no light pastime. M. L. Crossley, of the Calco Chemical Co., undoubtedly realized this when he prepared the paper which he delivered Tuesday evening in the conference room at the exposition. It was an earnest attempt to convey the story of the American synthetic organic chemical industry to the public.

Dr. Crossley had prepared a spectacular chart headed "Evolution of the Dye Race." He pictured "Adam" Coal, "Eve" Science and "Abel" Industry as progenitors of the race, showing the "descendents" of anthracene, benzene and naphthalene as dyed samples of cotton, paper, wood, wool, silk and leather.

The speaker outlined the history of the development of synthetic dyes up to the present time and dwelt upon the present status of the industry in the United States. He explained, in simple language, the relation between the dye industry and the organic chemical industry in general, but particularly its connection with national defense, sanitation and medicine. The interlacing of the dye industry with consuming industries was also discussed.

In concluding, Dr. Crossley touched upon the tariff situation, explaining that the continued existence of the industry depends upon adequate protection from the established German competition. He pointed out that the additional cost of goods to the ultimate consumer caused by the tariff would be practically negligible. As to the possibility of establishing a monopoly in this country, Dr. Crossley said, there is little possibility of such an occurrence, for about two hundred American manufacturers are engaged in the keenest competition. It is a case of choosing between this domestic competition and complete domination by the German cartel.

Ceramic Day

Friday afternoon the technical program was conducted by the American Ceramic Society, the general secretary, Ross C. Purdy, acting as chairman.

Feldspar Colloquium

A most important phase of the meeting was the feldspar colloquium. Some time ago dissatisfaction on the part of users of feldspar with regard to quality and price prompted R. B. Ladoo to make a thorough investigation of the situation. The publication of his report on feldspar and feldspar grinding brought forth much comment and considerable space in recent issues of the *Journal* of the American Ceramic Society has been devoted to the publication of discussions on this subject.

Several further contributions were received far

enough in advance of the meeting so that it was possible to have them available for distribution in mimeographed form. The papers read were chiefly comments on the mimeographed material.

The necessity for agreeing upon standard specifications was pointed out at length in a report by W. H. Landers. As the requirements of the three great groups of users—the manufacturers of pottery and tile, enamel ware and glass—differ considerably in many particulars, it will probably be necessary for each group to outline its own standards rather than attempt any uniform specifications for all users. In many cases little exact information is available regarding the effect of various impurities in specific applications.

Take the case of iron. With the exception of the glass trade, where the effects of iron are definitely known, it does not seem clear, outside of the question of forming black specks in the ware, just what results from the presence of iron, and whether the same effects are obtained from the various oxides of iron as are noticed from metallic particles only. In addition to the iron which occurs naturally with the feldspar, appreciable amounts may be added as a result of carelessness during mining, grinding and handling.

After considering a number of other factors, Mr. Landers turned to the question of fineness, which must be considered from the users' standpoint. For the potter, it is customary to grind so that less than ½ per cent remains on 140-mesh Tyler standard screen. The enamel trade would like to get a feldspar free from lumps, which would leave no residue on an 80-mesh screen and contain no material finer than 250 mesh, as the very fine material causes trouble by forming lumps. The glass manufacturer could quite profitably use feldspar which had passed through 40 mesh but remained on 100, and contained not over 10 per cent finer than 100.

The mutual benefit which would result from the adoption of workable specifications for each branch of the trade is self-evident.

In a paper discussing Mr. Landers' report, Raymond B. Ladoo emphasized the need for standardization and registered his hope that definite action be taken soon. He suggested that the whole subject of feldspar specifications for various uses be gone into very carefully by a committee composed of both producers and consumers of feldspar.

Other phases of this timely and important subject were presented by George M. Darby, O. O. Bowman, 2nd, V. A. Stout, C. R. Moore and C. M. Franzheim.

Fineness of Grind and Screen Analysis

Two other papers had a direct bearing on some of the topics considered in the colloquium. Eric Turner showed an apparatus for quickly determining the fineness of grind, which is the factor determining the finishing point when grinding such materials as feldspar and flint in the intermittent type of pebble mill. The residue obtained by washing a 300-gram sample through a 160-mesh brass screen of the Tyler testing type is washed into a long-stemmed funnel, where it is permitted to settle. The stem is graduated in tenths of 1 per cent, so that the percentage of oversize material may be read off directly.

The whole subject of the value of screen analysis in ceramics was treated in a most comprehensive way by F. P. Nickerson, of the W. S. Tyler Co. Illustrations were given of practical results obtained from the use of screen analysis curves in the form of either cumulative direct plots or cumulative logarithmic plots.

Gray Enameled Ware

Problems encountered in the production of single coat mottled gray enamel ware formed the subject of an interesting paper by Howard C. Arnold. Briefly, the points which have to be considered are these:

The black shape has to be covered completely in one coat. The lack of a second coat makes it impossible to hide blemishes and imperfections. This coat must have all the gloss, luster and appearance of a finish coat. The two colors must be produced from the same enamel in one dipping. The two colors must be present in correct amounts and so distributed as to produce a pleasing effect. The chemical reactions which produce the two colors in the single coat introduce many troubles not met in two or three coat work.

Gas Producers for Glass Works

A most instructive talk on the development of gas producers for use in connection with glass furnaces was given by W. B. Chapman, of the Chapman Engineering Co. By means of lantern slides the steps in the progress from the old stationary producer to the present mechanical type were clearly shown. Mr. Chapman also had a model of a new type of closed pot furnace designed to replace furnaces of the reversing type. The pots are set in a circle with the burner at the center. The flame passes over and down the sides of the pots, then through flues in the bottom of the setting, where some of the heat is given up to the incoming air supply in adjacent sets of flues. The gas is not preheated, as it comes from the producer at 1,000 deg. F.

Other Papers

High-temperature cements were discussed by W. H. Gaylord, Jr., of the Quigley Furnace Specialties Co., and Charles E. Kraus of Johns-Manville, Inc.

According to G. O. Dickey, of the Industrial Filtration Corporation, the difficulties of handling clay mixtures containing a large proportion of ball clay on rotary filters have been overcome in a special continuous filter which will handle any kind of clay. The removal of iron from clay slips and glazes by means of magnetic separators was considered by E. S. Hirshberg, of the Dings Magnetic Separator Co.

Chemistry in Medicine

At the Wednesday evening session Arch E. Olpp, a physician and member of the House of Representatives, was introduced. In discussing "Chemistry in Medicine," he mentioned the fact that originally the chemist worked to produce drugs for the physician and that later had come a not unnatural split—the chemist turning toward industry in the days of Agricola. Later the physician turned back to his former aid and found most useful substances awaiting him. For example, ether was discovered in the thirteenth century, but its value as an anesthetic was not definitely recognized until 1846; during the interval of five or six hundred years untold suffering resulted from the lack of knowledge of its application to produce insensitiveness to pain.

So today the medical departments and colleges are devoting much more attention to chemistry than heretofore, evidently realizing at last the great necessity of co-operation between these two sciences.

Dr. Olpp instanced a number of examples of the

chemists' skill in preparing drugs and medicines, one notable example being salvarsan.

By the study of the structures of the molecules of a number of dyes, the key to the whole mystery of color production and color quality has been gained by man. Therefore, by such conquests we can readily appreciate the necessity for the co-operating work of the chemist, biologist and physician in an ultimate conquest in the domain of life products.

Thus, for example, cocaine has at least forty-three atoms in the molecule, arranged in a peculiarly complex, labyrinthal fashion, and it took three successive attacks by leading chemists to reach a final solution of the problem.

It was found that only part of the molecule has the beneficent anesthetic effects of cocaine, while another is related to the deadly principle of hemlock, coniine, famous as the poison Socrates drank, and a third part is related to nicotine. And from this the chemist reconstructed new and less harmful drugs—procaine, beta eucaine, apothecaine, which are better than cocaine and less poisonous.

Government Regulation of Industrial Alcohol

C. P. Smith, Assistant Commissioner of the U. S. Internal Revenue Bureau, then discussed the government regulation of the industrial use of alcohol. He pointed out the three phases of the national prohibition act: First, to prevent the sale of alcoholic beverages; second, to encourage the manufacture of industrial alcohol, and third, to control the distribution of high-proof alcohol. The latter is a big problem and one phase of it is illustrated in the quotation given below.

"Heretofore applications of permits to purchase alcohol for manufacturing purposes have generally been granted where nothing can be found against the applicant. The result has been the granting of thousands of permits to persons desiring to manufacture hair tonics, flavoring extracts and patent medicines. The situation in the flavoring extract industry is demoralized. It is needless to say that much of the alcohol sold to these small manufacturers for industrial purposes is utilized in the making of 'bootleg' whiskey. It is very probable that there will come a time when a man must show more than that he has never served a jail sentence before he will be entitled to receive a permit to purchase pure alcohol for manufacturing purposes. That day will be hailed with delight by legitimate users of alcohol."

The American Chemical Society Meeting

On Friday evening, Sept. 15, the New York Section of the American Chemical Society held a meeting at the Chemical Exposition. A symposium on standardization had been prepared and a number of papers on the subject were to be presented. Dr. Martin H. Ittner, chairman of the New York Section, called the meeting to order and introduced Dr. W. D. Collins of the U. S. Geological Survey, who made a plea for moderation in standardization. The advantages of standardization are very apparent and it so happens that natural conditions of trade bring about a great amount of standardization without conscious effort. The author advises against ill-considered standardization as being costly, with losses which far outweigh the gains. The author conceived his text from the experience of the chemical laboratory apparatus manufacturers where an apparent capriciousness on the part of the consuming public may not be capriciousness at all and therefore too great standardization and too great elimination of existing types of apparatus may be distinctly undesirable.

I. G. Jennings, of the Glass Container Association, followed with a discussion of the problems which are to be met by this association in making standard specifications. Mr. Jennings recommended co-operation between the industry and the consumer and announced that his association would be glad to further such co-operation to the fullest extent possible.

The Hoover Method Explained

The chairman then introduced William A. Durgin, of the U. S. Department of Commerce, who told the Society about the Hoover idea. Mr. Durgin's talk was well illustrated with lantern slides and was on the whole very refreshing. He began by disclaiming any desire on the part of the Department of Commerce so to standardize life that the wearing apparel of the citizens would be uniform and that the size and shape of the clouds which hung over the city would also be standard, but he went on to outline the many advantages of standardization and gave specific examples from a dozen or more industries. Such things as berry baskets, writing paper, tile and brick and many other commodities have been standardized so that there are now somewhere in the neighborhood of 10 to 15 per cent of the number of kinds originally manufactured. The Master Car Builders Association has eliminated 96 per cent of the parts which formerly had to be kept in stock. This has effected a tremendous saving. The story of beds is another interesting chapter. Furniture manufacturers made beds of almost any size. In fact, they were rather hostile to the idea of standardization, stating that designers could not be hampered by dimensions. This led to an innumerable quantity of mattress sizes, which now have been cut down to a reasonable number. The Hoover method is, first, a publicity campaign in a particular field, then a scientific survey of the conditions in that field followed by a general conference of the manufacturers with representative consumers under the auspices of the Department of Commerce. It is essentially a peace-time application of the co-operation which we first learned was possible during the war.

Secretary J. M. Roberts of the Apparatus Manufacturers Association told of the advances which had been made in that field during the past year. The industry has had an interesting problem on its hands inasmuch as it is so new in this country. The first questionnaire sent out by the association gave 80 per cent full agreement by manufacturing firms and approximately 80 per cent agreement on the part of the consumers (through the American Chemical Society's committee) on the elimination necessary. There were originally 148 gas burners on sale in the country and 70 of these have been eliminated. Over 10,000 lipped beakers are sold to less than 100 without lip. Knowledge of this figure made possible an elimination of 31 out of 48 sizes. Similar corrections have been made in other types.

The next paper, by Ross C. Purdy, secretary of the American Ceramic Society, is printed in full on another page of this issue.

The symposium was closed by a set of pictures presented by Emerson P. Poste, of the Elyria Enameled Products Co., on standardization of enameled ware for chemical purposes. The pictures were most interesting and bore evidence that close co-operation exists among manufacturers of these materials.

Standardization of Refractories*

By Ross C. Purdy
General Secretary, American Ceramic Society

STANDARDIZATION of refractories has been the desideratum of manufacturers and users of refractories the world over for several years. Technologists and scientists have made researches and developed methods of tests; associations have adopted so-called standard tests and definitions; associations of manufacturers of refractories and associations of users of refractories have joined with the federal bureaus and with collegiate institutes in conducting searching investigations of the required refractory properties for each of the many industrial uses; individual industrial concerns, both producers and consumers, have been spending annually large sums of money in searches for refractories that would best serve specific purposes.

Co-operation Among Searching Agencies

This earnest searching has been in progress for years not alone in one country but in all the industrial countries. All these searching agencies, private, semi-public and public, associated and individual, have published freely their results and all have co-operated to their limit in every attempt to standardize tests and to write specifications for refractories for specific purposes. Technical and scientific societies have had research committees collaborating with all the institutional and industrial groups. Nothing has been left undone that could with intelligence have been done by any of these several agencies to hasten the day when standardizations and specifications could be agreed upon not alone in one country but also internationally.

Progress Has Kept Pace With Knowledge

Much exact information has been gained and great progress has been made by and through all of these efforts. The many things that apparently conflict are rapidly being aligned and the fundamental facts quite generally understood by the producers and the users alike. It would have been impossible to have made more rapid progress than has been made in determining the fundamentals of the problems involved. There can be no just criticism or reproach made because of inadequacy of our present knowledge of the fundamental requisites to the making of satisfactory standards and specifications, and that which I will relate as my understanding of the present-day situation should not be considered iconoclastic or critical. Nothing short of most sincere praise for and genuine satisfaction with the accomplishment to date should be expressed, but we must face the facts viewed in the light of the present-day requirements.

Increasing Severity of Industrial Requirements for Refractories

The industrial requirements for refractories have been steadily increasing in severity; the refractories that were satisfactory in the furnaces and with practices of the immediate past will not meet the present-day requirements. New demands, much more severe than any heretofore known, have developed with the introduction of electric furnaces and with the efficiency studies directed to lowering of costs of manufacturing, calling for certain properties not possessed by the refractories of the immediate past. It has been impossible to write specifications or to adopt standards that would for a reasonable period of time satisfactorily fit with the changing industrial requirements. This is not an alibi; it is not an excuse; it is merely a statement of facts.

Classification of Refractories

Refractories may be classified according to the material of which they are made; such as clay, flint clay, bauxite, diaspore, fused alumina, corundum, chrome, magnesia, zirconia, silica, silicon carbide, carbon, nitrides, etc. We are rapidly learning where each of these classes of brick serves best.

No one, however, can today intelligently sub-classify any of these types of refractories into No. 1, 2 and 3, or *a*, *b* and *c*, except in relation to some given property such as temperature range through which it resists tendency to deform.

The industrial condition in each and every case calls for a combination of several requisite properties in refractories, the emphasis on particular properties varying in what superficially appear to be identical requirements. Malleable iron foundries will have differing requirements. So will furnaces in other industries, depending upon the particular conditions of the individual plant operation.

Satisfactory Classification Not Possible With Present Knowledge

Classification of refractories as "heavy," "medium" and "light duty" based upon properties disclosed by standardized tests is, in a very general way, satisfactory for particular purposes, but the "heavy duty" refractory suitable for one industrial purpose will not be the "heavy duty" refractory for all purposes.

No classification of refractories yet made is satisfactory, and I confess frankly that I do not possess requisite information for recommending a satisfactory and just classification.

Standard Tests Do Not Check With Operating Results

Committee C-8 on refractories of the American Society for Testing Materials has compiled all the known information on methods of testing and has made very successful attempts to standardize the tests. The inadequacies in the standard tests as they stand today are due altogether to the inadequacy of our knowledge of industrial requirements. That the standard slag test fails utterly to disclose which of two blocks would resist slag corrosion in a cupola furnace is due wholly to the inadequacy of our knowledge of the cupola conditions and of the properties in refractories necessary to best meet them.

In a certain test, privately reported, two cupola blocks showed striking contrasts in results in the actual furnace test and in the standard slag test. In practice the slag did not penetrate more than 0.25 in. in depth, while in the standard test the penetration amounted to 0.5, 2.0, 2.5 and 3.5 in. In practice the penetration and corrosion were rather uniform, while in standard test it was not. In practice the *B* blocks were better by 400 per cent, whereas in the standard slag test the *A* blocks were better by 50 per cent.

The coarser grog blocks, *B*, although permitting greater penetration, actually resisted corrosion far better than did the *A* blocks.

A fair test of the present status of our scientific knowledge of the factors involved in this case would

*Paper presented at the Eighth National Exposition of the Chemical Industries, Ceramic Day, Sept. 15.

be to submit the analysis of these *A* and *B* blocks—as given in the accompanying table—to any ten ceramists or chemists as a basis for prediction as to which one of these blocks would most successfully withstand corrosion in a cupola furnace.

ANALYSIS OF CUPOLA BLOCKS

	A	*B*
Silicon oxide	52.70	57.84
Aluminum oxide	38.17	34.14
Ferric oxide	6.30	2.75
Calcium oxide	0.18	0.30
Magnesium oxide	0.13	0.58
Total alkalis	0.93	1.39
Totanium oxide	1.89	2.75
Total	100.30	99.75

A was made of finely ground material and hard burned and *B* was made of coarsely ground material and only medium hard burned. Both fused at cone 31.

Modifications Required for Specific Cases

It would require much more time than has been alotted to analyze critically all of the "standard tests" as to their inadequacies when applied to a given industrial requirement. All of them will be subjected to refinement as knowledge is obtained, but each and all of them represent the best that can today be written. This broad justification can be stated notwithstanding the fact that whenever a set of standard specifications is attempted for refractories for a specific purpose, good reasons have appeared for a modification of most of the standard tests.

Just recently a selected group of technical men representing the users and producers of boiler refractories wrote specifications in collaboration with the best informed ceramists in this country. When the specifications were applied, they found that over 50 per cent of the refractory bricks which were known to be giving satisfactory results were, according to the adopted specifications, condemned, while some bricks which were known to be unsatisfactory in boiler construction met the specifications satisfactorily.

Suitability and Control Tests

We can today specify "suitability" and "control" tests for refractories for specific purposes. The federal departments have done a great deal, as have many of the users of refractories, in determining suitability tests. These, however, cannot be used as the basis of standards or specifications.

Data on Service Conditions Needed as Well as Fundamental Facts

The American Society for Testing Materials and the Refractories Manufacturers Association are laying plans for a joint survey with the several industrial associations to obtain exact information concerning the conditions under which refractories are used. Based on this information the A.S.T.M. Committee C-8 expects to be able to prepare standard tests which will apply in each industrial case and the manufacturers and users will be able to decide upon "suitability" and "control" tests.

This sort of close co-operation on the part of the several industrial and technical associations, contemporary with the new fundamental facts which will be brought forth by the several laboratories, will hasten the clearing of the present apparent chaos. Then and only then will it be possible to standardize refractories.

Investigate Zirconia-Alumina Refractory Crucibles for Steel

Difficulty is experienced in obtaining a refractory crucible, other than ones of carbon, which will not react with the carbon in steels and give fictitious values for carbon monoxide. The most promising results obtained to date from crucible tests have been secured with a refractory of zirconium oxide (practically free from silica) with the admixture of 10 per cent of aluminum oxide. The latter addition is made for the purpose of improving the mechanical rather than the chemical properties of the crucible. A medium-carbon steel melted in this type of crucible was quite easily pumped free from gas while still molten and the carbon in the vacuum-melted metal was only slightly lower than in the original sample. It is, therefore, to be concluded that there is very little if any reaction between the oxides of this refractory and iron carbide even at high temperature and low pressures.

The results obtained on electrolytic iron by the direct fusion method and by the Gorens (antimony-tin alloy) method have been compared. The results for total oxygen are practically alike. The hydrogen is higher as determined by the Gorens method. The ratio CO_2:CO was found to be 1:1 in the Gorens method but 1:4 in the direct fusion method. These differences are probably to be attributed to the lower temperature required in the alloy method.

Runs have been made on a medium-carbon steel by the two methods. The results are not yet conclusive, since the type of crucible used for the direct fusion of the steel was of a composition different from the other crucibles used in the test.

Canadian Topographical Survey Equipped for Thermometer Standardization

Until recently the lack of proper facilities for thermometer testing in Canada was such that scientific laboratories and others found it necessary to send their instruments outside the dominion if tests of a high order were required. Since the Department of the Interior established a thermometer section at the Surveys Laboratory of the Topographical Surveys branch this procedure is no longer necessary. Thermometers tested at the Surveys Laboratory include precise instruments for scientific work and also industrial, clinical, high-temperature and meteorological thermometers. These thermometers are calibrated and their various constants and corrections determined in terms of the standard temperature scale.

The nearest approach to an ideal or absolute scale of temperature—i.e., one in which every degree is of equal value—is given by a thermometer in which temperatures are measured by the expansion of certain gases. Even this is not strictly accurate, but the deviations from the ideal scale can be calculated. The gas thermometer is a very elaborate apparatus, and it has been found that a thermometer in which temperatures are measured by the electrical resistance of platinum wire will produce the absolute scale to a high degree of accuracy, if calibrated at several points on this scale. Hence this thermometer is now generally used as a reference standard for accurate temperature measurements by such institutions as the Surveys Laboratory.

With the precision now possible in scientific measurements appliances for testing thermometers must be of special construction and provided with means for closely controlling and measuring the temperature.

Sidelights on the Exposition

Random Impressions Indicate That the 1922 Exposition Made a Greater Appeal to Utility Than to the Colorful and Garish—Notes on Interesting Things, Both New and Old, Which Were Exhibited in an Attractive Manner

CONTRASTING the Chemical Show with the one held last year and with the earlier ones of previous years, it might be said that the industry has taken off its frock coat, and even its collar, and rolled up its shirt sleeves and was there for business. There were very few, or relatively few, spectacular exhibits appealing to the popular eye rather than the scientific eye, which have marked the earlier shows. But there was a wealth of technical material, which made the show extremely profitable.

CONSIDERABLE INTEREST was evidenced in the vegetable chars on exhibit. Darco and Suchar seem to be traveling much the same road that Norit traveled about 4 years ago, before the vaulting ambition of its inventor o'erleaped itself. These chars have been tried out on plant scale and results have been satisfactory, but the length of use of the chars and the possible regeneration of them has only been touched on. That is the ultimate stumbling block for all chars in sugar work.

MATERIAL HANDLING is coming more and more into its own in chemical industry, and therefore it is not strange that a miniature material handling exhibit, such as the Dow Company of Louisville, Ky., put on, was observed with great interest. Of course, we none of us quite outgrow the joy of seeing the wheels go round, and even now you will see grown men crowd around F. A. O. Schwartz's window and watch little electric trains glide around on tracks. And it may have been some such impulse that made the crowd pause and watch the little boxes and barrels go up the belt conveyors and around down the incline rollers on the Dow apparatus. In any case, it was one of the high spots.

PERHAPS it was a similar childish impulse that made the crowd revel in the little models of plants for making bleach out of liquid chlorine, which were put on by both the Electro Bleaching Gas Co. and by the Mathieson Alkali Co. Both of these exhibits were quite significant because they illustrate conclusively the importance which liquid chlorine is assuming in industry. It is much easier to transport than bleaching powder, and with equipment such as was shown in the models is extremely easy to handle. It is likely to be an increasing factor in those trades which consume bleaching materials.

NEVER SAY the public doesn't appreciate true art. There at the Chemical Show was Ivan Petrovich (some abominable realist has said that his name was Lutz. It shouldn't be) working a potter's wheel at the General Ceramics Co. booth and the crowd watched him with much interest. He would turn out a beautiful pot all ready for baking, and then crumble it up into a shapeless mass and make clay of it again. That is really the essence of true art, to create a beautiful thing and then to smash it. You have satisfied the creative impulse, and you have not bartered your soul to mammon in doing it. Anyway, it was fun to watch him, and his name might not have been Ivan Petrovich, but it must have been something which was not Kelly or Lutz. Incidentally, it was interesting to see the unbaked clay from which good pottery, acid-proof stoneware, is made.

HEAVY CHEMICAL MANUFACTURERS were quite noticeable by their absence, and it was with immense relief that one observed the Merrimac Chemical Co. booth, for it was one of the few evidences at the show that America had not gone out of the heavy chemical business. One unique feature of the Merrimac booth was the miniature containers, exact replicas of the life-sized barrels and drums and carboys which the Merrimac sends out, with the colors painted on and the lettering exactly as it occurs in commerce.

MANY'S THE TIME we have wanted to do some experiments at home, but have been restrained by fear of the wrath which descends upon those unlucky enough to get acid on the bathroom floor, or foolish enough to store cultures in the refrigerator next to the baby's milk. So that the sight of the neatest little table built by the Kewaunee Manufacturing Co. for a private laboratory filled us with the sudden desire to order one for the library. It looks more like a desk than a workbench, the brass connections for gas, water and electricity being not at all conspicuous. The stone top has a combination sink and basin built into it at one end. A microscope cupboard on one side, deep drawers at the other to hold reagents and supplies, and a shallow drawer across the top for miscellanea would appear to be adequate for nearly every demand.

CHEMISTS should not object to the synthetic orange drink served here and there, especially when adulterated with a scraping of rind. But a metallurgist would acknowledge that it is a good deal like circus lemonade —cold but not a quencher.

MEN AND WOMEN would rather "make believe" than do anything else. Children dress up in grown-up clothes and play house. Even Mr. Bryan, knight errant against all frauds, has bought a toupee. And the rest of us like to put on a good appearance, even in our work.

We always relished the thought of the early land surveyors on the Western plains. The pretty maps which they filed in the Land Office show that they carefully measured, with transit and tape, all the borders of the sections and townships and planted the corners into the ground according to law. But they didn't, they were frauds; they climbed into a wagon, drove along, and every now and then kicked out a stone. It must have been fun!

Once we saw some other frauds. They were traveling up and down the country roads in a Ford, in an aimless sort of way, like people who had no place to go and had lost their way. But they weren't. In the back of the machine they had a little box, and in it some glassware, by which they could analyze the air for one or two parts per million of SO_2—about a tenth of a smell!

Now the dairymen and creameries must be on the lookout for a smooth actor. He will come along with

a natty leather suitcase, which he got from the Central Scientific Co. He will look like a college chap asking his way to the railway station. But the suitcase doesn't contain socks; all packed away in the cosiest sort of manner is lamp, beaker, test tubes, slides and all the paraphernalia of Frost's field outfit for counting bacteria in milk.

WE RAN ACROSS an old friend we hadn't seen since doughboy days and were quite surprised to find him still in pursuit of the dogs of war. "Buddy," he said as we passed the exhibit of the Mine Safety Appliance Co., "it was a durned good thing these scientific birds had 4 months and not 4 years to make those gas mask chokers we wore in France. Take a slant at that complicated contrivance over there! It looks like a cross between a gas mask, a moving picture machine and a Ford engine—and I'll bet it weighs 150 lb." Our exaggerating companion was apparently referring to the new Gibbs self-contained oxygen breathing apparatus and some of its highly efficient accessories. Automatic cooling systems for the canister, timing devices definitely controlled by inhalation and exhalation and absolute protection against CO are some of the refinements that have found their way into gas masks since some of us used them in Sunny France.

SOMETIMES a combination of circumstances or events or even well-known chemical engineering equipment will produce more or less startling results. Thus whoever hit upon the idea of running an endless conveyor belt over a rotary vacuum filter, compressing the cake into the belt and finally passing belt and cake into a chamber drier deserves credit for bringing together in a practical way two of our fundamental chemical engineering operations. Proctor & Schwartz of Philadelphia and the Filtration Engineers, Inc., of New York had a joint exhibit of just such an ingenious combination in their new continuous filter and drier. In operation it was shown to work somewhat as follows: The vacuum filter drum revolves in a slurry of the material to be filtered, which is deposited on a woven wire conveyor belt.

Rolls of the cake compressor squeeze out the excess moisture and a thin, continuous cake, firmly enmeshed in the belt, passes into the drying inclosure. There it is automatically hung in loops or festoons for drying by heated air. At the delivery end of the compartment the dried material is beaten loose from the belt and falls into a hopper, from which it is removed by a screw conveyor.

We have been told that installations have already been made for drying certain pottery clays and decolorizing carbons in this way and it would seem that this is merely the beginning of a broad field of usefulness.

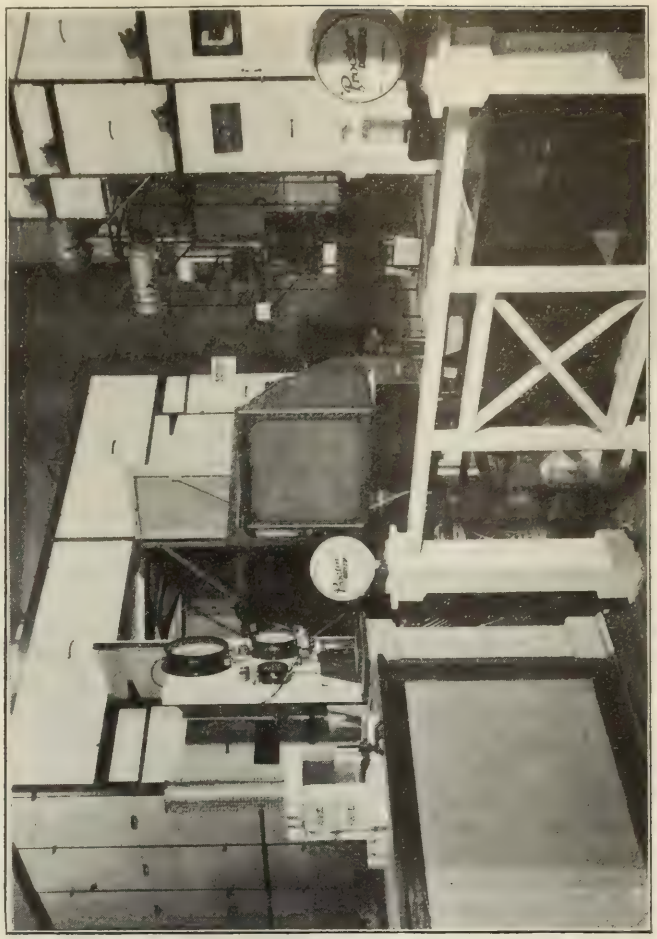
WHEN YOU ARE in the laboratory it is a comparatively simple job to make bleach liquor from chlorine gas. But when you are in a pulp or paper mill and want to make a 10,000-gal. batch in the same way you run up against a number of man-sized difficulties. Had you been at the Chemical Show, however, you might have found a solution for your problem in the two systems demonstrated there. The one shown by the Mathieson Alkali Works is brand new—in fact Mr. McMahon's patent was issued only Aug. 22, 1922. In it the operation is carried out by filling a concrete tank with just enough hydrated lime and water to react with the chlorine from a standard container (and it will be recalled that the Mathieson company has a decided preference for the 1-ton drum). The liquid chlorine is led from a pipe into an expansion coil within the tank. Here advantage is taken of the latent heat of vaporization of the liquid chlorine to counteract the heat developed by the reaction of the lime and chlorine. The gas from the coil is sucked into the pump that keeps the liquor in continuous circulation. After the chlorine in the container is exhausted, the clear bleach liquor is drawn off and the batch is completed.

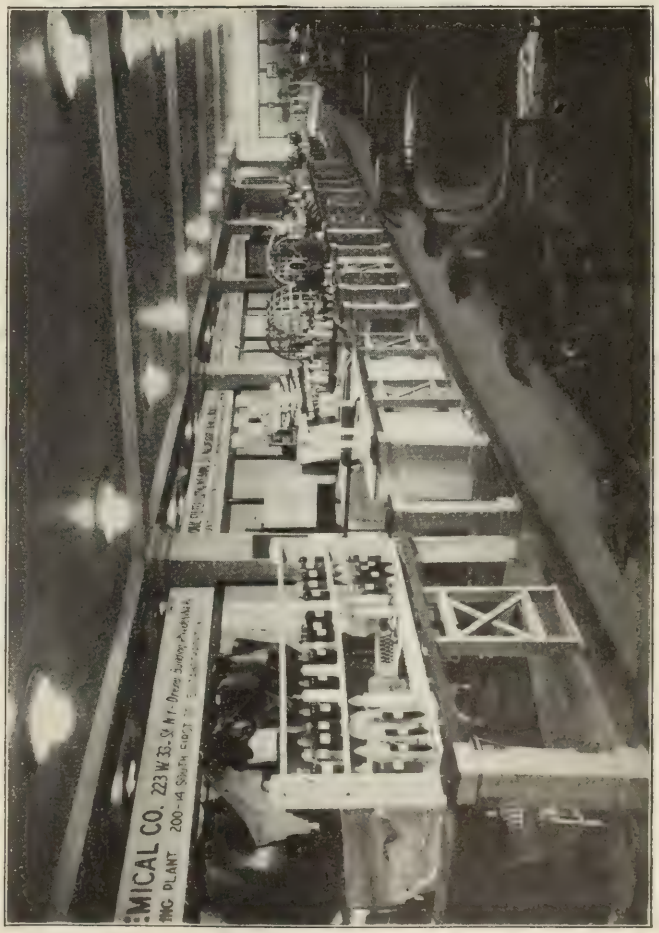
The older of the two systems is that of the Electro Bleaching Gas Co., which boasts of an operating installation as far back as 1919. Briefly, the system is made up of a circulation tank, a sludge tank, a centrifugal pump, an absorption tower and a storage tank. A measured quantity of lime and water is continually agitated in the tank and the solution pumped to the top of the stoneware absorption tower. The chlorine gas enters at the base of this tower, where countercurrents of gas and solution afford suitable conditions for the reaction.

Circulation is continued until the desired strength of liquor is obtained or, if chlorine containers are used, until the supply is exhausted. If the chlorine comes in tank cars (and, you know, Electro Bleach likes to ship it that way), the gas is either measured through a flow meter or the strength of the liquor is determined by titration.

THE TEXAS GULF SULPHUR CO., besides its general exhibit and suggestions for new uses of its product, had one display with a story attached to it. Gulf sulphur is all at least 99½ per cent pure. But it all contains also from 0.002 to 0.5 per cent crude petroleum. Now, when sulphur is burned in a pan, this minute quantity of oil combines with the sulphur to form a very thin asphaltic film which puts out the fire. If one stirs it with a stick or if the sulphur is burned in a rotary kiln, the difficulty is overcome, but that does not satisfy the hop growers, prune producers, makers of other dried fruits, woolen manufacturers, bleachers of grains and others generally interested. Experience teaches that it is unprofitable to stir up burning sulphur with a stick in a closed room during a bleaching process, and rotary kilns are cumbersome. After a year's unsuccessful research in an endeavor to extract the oil or to provide a simple mechanical device to take the place of the convenient pans, it occurred to a gentleman connected with the company that, if the pans were lighted and set zigzag, one on top of the other, they might help one another along in combustion by the excess heat developed and thus overcome the film. Presto! It makes the sulphur boil, works completely (and the notion is patented).

THE ANACONDA CO. made an interesting display of hundreds of different forms of copper, zinc, lead and their alloys and compounds, not forgetting copper shingles in greens, browns and other shades. In addition to these tonnage metals, other rare ones like tellurium and selenium are recovered. Although they exist in the ores in almost indistinguishable traces, some is recovered. It's an everyday application of the rather foolish mathematical truth that zero times infinity may be finite. The company has sold over a ton of tellurium for radio detectors alone. When we consider the small fraction of a gram in each detector, we get a notion of how many people are listening in to





MICAL CO.
INC PLANT

the broadcast "entertainments." And they say the glass industry takes all the selenium the company can produce.

THE CONTINUAL CRY, "Filter press has got to be cleaned!" which makes the life of a raw sugar manufacturer miserable, may not be heard, ever again. At least not if Messrs. Petree and Dow succeed in disposing of enough of their "cane juice clarifiers." This is a modification of the Dow tray thickener and the company claims that $2 legal currency per ton can be saved if you install this apparatus in place of filter presses. They like to deal with people from Missouri. A good deal of interest was developed in this apparatus and in the booth itself—for many lady visitors mistook the white wicker furniture and pink cretonnes for some kind of a nursery exhibit.

THE FENCE around the booth of the Corning Glass Works had 6-in. Pyrex tubes for posts and the rails were 3-in. pipe lines of the same material. This was but a little of the outside evidence of the recent development of Pyrex glass in industrial shapes and sizes suited to the needs of the chemical manufacturer. A 12-in. tubing is offered for chemical towers, which, in addition to its resistance to acids and temperature changes, has the advantage of enabling one to observe what is going on inside. These tubes withstand temperatures up to 600 deg. C. Other examples of industrial ware include 3- to 6-in. socket pipes and bends, distillation retorts containing up to 12 liters, 18-in. evaporating dishes, carboys, cylinders, etc. Within 6 weeks it is reported that 25-in. dishes holding 10 gal. will be on the market. "S" bends capable of use in many practical operations, such as cooling hot acid gases and liquids, in acid-condensing systems and for conveying hot liquids from condensers to receivers, are already being manufactured in various bores and lengths. One that has proved popular in distillation sets has an inside diameter of 2 in. and is 72 in. long.

But speaking of some of the domestic utilities of Pyrex, an unexpected convenience is to be found in an infant's nursing bottle which may be sterilized with boiling water without danger of breakage. Ardent testimonials from fathers with legs sensitive to the cold have followed the decreased time factor in preparing baby's meal on a freezing night when baby has announced his readiness to receive it.

In closing this little squib we are forced to add a plaintive note of despair. The remains of our beautiful Pyrex cigarette holder now repose in the gutter. Alas, its brief journey through life was suddenly and painfully interrupted by an accidental collision with the cement sidewalk!

AIR CONDITIONING, for the good of the product and for the health and comfort of the workers, has been the topic of much recent discussion. So it is natural that the Chemical Exposition should have its full quota of exhibits of conditioning apparatus. These exhibits ranged from the simple apparatus capable only of humidifying an atmosphere deficient in moisture to the elaborate units by means of which absolute control may be maintained over moisture and temperature within the building walls, regardless of the condition of the entering air.

Among other exhibits of this type the writer's eye was caught by the Bahnson Humidifier. Here is an extremely simple piece of apparatus—the principal part being an ordinary electric motor driving something which looked like a turbine impellor. It provides positive air circulation and will increase the humidity to any desired point above that of the entering air. And this without the aid of any auxiliary apparatus. The control depends on the moisture content of the atmosphere in the room which is being humidified, is positive and gradual in action and can be set to operate at any desired degree of saturation.

To go to the other pole of air conditioning, the B. F. Sturtevant Co. and the W. L. Fleisher Co. exhibited a complete, self-contained and compact unit for air conditioning, including refrigerating coils by which any temperature of entering air and any degree of humidification or dehumidification could be maintained as desired.

WHAT SHALL WE MEASURE NEXT? There seems to be a recording meter for almost every possible property that any possible form of matter could attain. There have lately been rumors of a recorder for measuring the specific gravity of liquids and, sure enough, we found it prominently exhibited by the Bailey Meter Co. at the show.

EVERY SHOW must have its mystery. And from the comments of the crowd, I should say that a goldfish bowl in the booth of Elyria Enameled Products Co. was the enigma of the year. People saw the bowl resting upside down on a nice blue-enameled surface—while the water stayed in and the fish swam contentedly about. "How do they do it?" everyone asked. And they felt the enamel and found it had just enough wavy feel to make the thing seem improbable, to say the least. Anyway, it was a nice piece of enamel!

IT HAS ALWAYS BEEN a pet theory of the present writer that the control of the generation and application of power in the average plant of a chemical or allied industry must be in charge of the plant engineer and that that plant engineer would be, nine times out of ten, a chemical engineer. This view is also, apparently, the view of the makers of power generating and control equipment. Every year shows a better representation of this class of apparatus at the Chemical Exposition.

SUCH AN OPERATION as the placing of a label on a bottle, can or other container may not seem of marked importance, but a surprising amount of time and money can be wasted where this is not efficiently done. That such considerations are uppermost in the minds of many just now was clearly demonstrated by the interest shown in the various exhibits of labeling machinery. The modern labeling machine, either automatic or hand operated, can place practically any kind of label on any shape of container, from a wooden packing box to a tiny vial of perfume.

SURPRISING AND NOVEL RESULTS are often obtained by the simple expedient of reversing the principle employed in some familiar device. At first sight the long boxlike affair displayed by the Carborundum Co. seemed to bear little relation to other parts of the exhibit, but in fact it was simply the reverse of the carborundum

uffle shown in another corner. Build a muffle of carorundum plates with a horizontal baffle, burn fuel—oil, as or powdered coal—inside of this and you have the annon radiating furnace. The high thermal conducivity of the wall material favors rapid radiation of the eat, forming an ideal heating unit for many purposes. When applied to boilers it is claimed by the makers hat an efficiency of 7 b.hp. per cu.ft. of combustion pace is obtained.

SEVERAL BOOTHS were occupied by chemical societies nd organizations of various kinds. Most of them were urnished with comfortable chairs, and were intended or meeting places and lounges. The "baby" of them ll, the Technical Photographic and Microscopical ociety, endeavored to show how photography is being sed by industry. Its exhibits overflowed the railing. Iundreds of fine prints were mounted on the assembly oom halls—ranging all the way from aërial mosaics aken 10,000 ft. high to glimpses of organisms observble only at 1,000 diameters.

To a metallurgist or a metallographist, by far the nost striking was a series of micrographs of aluminum lloys, made at McCook field by the Army Air Service. Aluminum is notoriously difficult to polish and etch, so nuch so that early investigators thought the metal nique in possessing no crystalline structure. Yet here re views at 500 diameters, taken of polished surfaces, *inetched,* showing two or three constituents in the most ninute detail and wonderful contrast!

EXTRAVAGANTLY DESIGNED DISPLAYS have been succeeded by more conventional efforts. Even the rainbow-hued color and dye exhibits were few in number. Perhaps the Bakelite Co. would have received the prize for colorful and artistic arrangement of its products, he brilliantly colored, amber-like materials being very effectively shown. The dazzling white of metal and ights at the New Jersey Zinc Co. and the brilliant eds and yellows at the Anaconda Copper Mining Co. gave natural tones which could be surpassed with difficulty. The United States Industrial Alcohol Co. had some purple hangings and royally carved furniture which contrasted strangely with the paper cartons of Alcorub which flanked them.

STATISTICS ARE INESCAPABLE, and when you saw the red light flashing at the National Lime Association booth and realized that every time it flashed a ton of lime had passed the way of all good things, you couldn't help sympathizing with the next ton of lime and holding your breath until the light went on again and you realized that it had also had its throat cut. The flashing light, however, did bring home to the visitors to the show the fundamental value of this commodity and its increasing importance. The National Lime Association is undertaking valuable work in enlarging our knowledge on this important commodity. Ample evidence of this work was apparent at the booth.

PROBABLY THERE WASN'T over a bushel basket of coke at the Koppers Co. exhibit, but many a longing eye was cast at that much fuel, and it would be interesting to know who finally got the stuff before it was transported from the Chemical Exposition. This company was exhibiting a revision of its design of coke oven, which looks promising. Instead of having the fuel burn at one end of the retorts and then exit from the flues to the regenerators at the other end (in other words, instead of having a lengthwise combustion of the fuel), the gases flow up on one side of retort and down on the other. This makes for much more even burning, and the quality of coke will be more uniform throughout the length of the burner. It is also reported that it is easier to regulate. The U. S. Steel Corporation has already decided to install these ovens at Clairton and at another one of its plants. It will be interesting to see whether the independent coke companies will take up with the new oven as enthusiastically as the proprietors of it.

MANY OF THE LARGER DYE MANUFACTURERS who have always taken space at the show were conspicuous by their absence this year. The Newport Company had a rather attractive booth, and dealers in dyes, such as Bachmeier & Co. and others, were represented.

Perhaps the most interesting booth was that of Zinsser & Co., who were presenting samples of alizarine colors on various fabrics. A number of hats were interesting in that they were among the first hats dyed with bottom chrome alizarines and marked a new era in hat dyeing. Some excellent woolen cloth from the famous Worumbo Mills dyed with brown and black alizarines indicated the use of these dyes on finer grades of woolens and worsteds. In addition, there were skeins of silk and printed goods of various kinds. There was also some worsted and woolen cloth for suiting, the origin of which was not revealed, but which was very satisfactory cloth. The successful distribution and use of these dyes make an optimistic note in the somewhat gloomy dye forecast. Here are colors which will compete with Germany on her most sacred ground of fine dyestuffs.

WE DOUBT if there is a chemical engineer in the country who has not at one time or another tried to dope out some way of measuring a quantity of water or other given liquids. They have struggled with the calculation of the V-notch meter and recording devices therefor. The Johns-Manville exhibit was, therefore, very interesting to them. This company has developed a meter which works on air pressure. The liquid fills up a cylinder on one side and is then discharged through a siphon while the liquid fills up its twin cylinder. Each time the cylinder discharges, a small cyclometer registers the fact that a unit volume has passed through the apparatus. The salesmen at the booth were either reticent or ignorant of the method of operation of the instrument, and no diagrams were available, but it was a very interesting advance and looks extremely promising.

LET US CONSIDER for a moment the case of an organic chemist with an idea the commercial development of which has been delayed only because of difficulty in obtaining the requisite quantities of a certain product—a compound answering to the name of furfural. At each exposition he has searched in vain for even a glimpse of the material which would mean success. Suddenly he stops in amazement, scarcely able to believe his own eyes, before a booth containing not simply a bottle of furfural but two standard drums!

So rapid has been the development of chemical industry that such an instance might be duplicated a dozen times.

Establishing a Rational Basis For Industrial Analyses

The Elements of Production Are Equipment, Personnel and Materials—Analysis of the Costs Involved in Each Leads to a Rational Basis for Future Analyses—Method Illustrated From Statistics of U. S. Railroads

By Harrington Emerson
President, The Emerson Engineers, Inc.

THERE are three elements in modern production, three partners with equal rights if not with equal interests. These three are like the three legs of a stool, which must be the same length, but need not be of the same thickness.

The three elements are:

The equipment.

The personnel.

The materials.

The function of each is different. The equipment does the work, the personnel supervises and directs the equipment which fashions and changes the materials.

These three are combined into a simple formula:

Product = Equipment Costs + Personal Compensation + Materials Used

Basic Example From Railroad Operation

In order to make the matter clearer, we shall illustrate all the steps, by using for the purpose, railroad operations.

Product, $1,000 of revenues, should be produced by equipment charges of $400 + compensation of $400 + materials $200.

The question immediately arises as to why $400 for equipment charges, why $400 for personal compensation and why $200 for materials?

To operate a railroad, there must be roadway, track and rolling equipment. These must come up to certain standards which the public and its representatives have grown to expect.

I have traveled on railroads where the only accommodation was an open flat car and where, under penalty of not arriving in time for dinner, the passengers had to cut wood for the locomotive. This would scarcely be tolerated anywhere in the United States.

It is demanded of a railroad that the transportation it furnishes shall be safe, convenient, frequent, rapid, punctual, comfortable and, lastly, decent. Each one of these requirements adds to the first cost of the equipment and also to the operating expense.

What Equipment Charges Comprise

If we examine the records of all the Class I railroads in the United States, about 200, we shall find that the investment in physical equipment is on the average $3,000 for each $1,000 of revenues. Some of the best roads have kept their investment down to about $2,000 for each $1,000 of revenues, but they are exceptions.

We can consider that $2,500 of investment in physical operating property for each $1,000 of revenues is conservative and that less than this would give rise to complaint.

The possession of equipment, even if it is not operating, causes various expenses that are in the long run inevitable, even if, for a short time, a few years, they can be deferred or be capitalized. The items making up the various expenses which perpetuate the property are only a few, as taxes, exactions, insurance, rentals, depreciation (the anticipation of future shrink), amortization (the making good of past shrink), unpaying betterments and, finally, the return on the investment.

These items are best expressed in the form of a percentage rate on the investment:

	Per Cent
Taxes	1.5
Exactions	1.0
Insurance, rentals	0.5
Depreciation	4.0
Amortization	1.0
Unpaying betterments	2.0
Return on investments	6.0
	16.0

Equipment Charges Increases as Property Ages

No one of these can be neglected, and a most disquieting fact is that the older the property the heavier are the charges.

At first taxes, exactions, depreciation and unpaying betterments are very low. Against a new railroad in a new country, all the charges might be as low as 8 per cent, but over the whole United States at the present time they average 16 per cent.

The normal, expected investment is $2,500, on which the perpetuation charges are at the rate of 16 per cent, or $400 out of a normal revenue of $1,000.

If the revenue is low in proportion to investment, either because rates are forced down or because investment has been made too large, the perpetuation expenses would amount to more than 40 per cent of the revenues, making this leg of the industrial stool too long.

The American railroad equipment perpetuation rate is 16 per cent, but amounted to $563 for each $1,000 of revenues in 1921.

Compensation's Share of Revenue

It is also stated that personal compensation can amount to $400. Why? After paying the perpetuation charges of $400, there is $600 left for operation. Part of this is for personal compensation and part for materials. How much for each?

The experience of the last 30 years in North America and in the United Kingdom shows that the material expenses are almost exactly one-half the personal compensation charges. This happens to be the railroad personal and material ratio and it is unchangeable, since material costs in the last analysis consist largely of personal costs. When personal compensation rises as it did during the war, materials also rise. When material costs drop, it is because personal costs have dropped. Therefore, of the $600 remaining out of $1,000 of revenues, $400 can be appropriated for personal compensation and $200 for materials to be used in operation and maintenance. Then $1,000 revenues

= $400 perpetuation + $400 compensation + $200 materials.

This is exceedingly simple, but usually not understood and not observed. Because personal compensation has to be met regularly and because material bills must also be paid promptly and because many of the equipment perpetuation costs can be deferred, be ignored, be charged to capital, the very vicious condition has arisen of paying more for personal compensation and for materials than the revenues justify. Two legs of the industrial stool, the compensation leg and the material leg, are too long. Sailors know enough to keep a ship on an even keel. She must not be down at the head or down at the stern, or show a bad list. Industrially, railroads are badly out of balance.

The figures, actual and standard are:

Actual: Revenues = $156 perpetuation + $563 compensation + $281 materials
Standard: Revenues = $400 perpetuation + $400 compensation + $200 materials

Whatever is added to compensation and to materials is at the expense of perpetuation. The roads have been living, and are living, on their own fat and some of them have already starved to death. If it is necessary to pay $563 for compensation, then without increasing the volume of business, it would be necessary to increase revenues to $1,400, an increase in ratio of 40 per cent.

The Universal Formula

The formula, however, as above given, is too simple and elementary. Each of the items—equipment charges, compensation and material—consists of two factors, the quantity factor and the quality factor.

The universal formula is written as follows:

$$\text{Product} = tR + TW + QP$$

in which tR stands for the equipment charges, TW for compensation and QP for materials.

t = hours in year that the equipment works.
R = rate per hour of all the equipment.

Analysis of Equipment Charges

Assume the total railroad valuation at $20,000,000,000; then with the perpetuation rate of 16 per cent, the total perpetuation charges are $3,200,000,000 = tR.

There are 8,760 hours in the year, and if the equipment worked every hour, the rate R per hour would be $365,000.

Unfortunately on the average railroad physical investment works only 5 per cent of the time, therefore 438 hours in the year. This boosts the rate R up to $7,300,000 an hour. We all know, of course, that a railroad cannot work all the time as a waterfall does, or a pipe line; nor nearly all the time, as paper mills and glass plants do, or as many mines do; but a railroad could improve very much. It could utilize its equipment two-thirds of the time, as some ocean steamers do. It uses some of its equipment, now, 25 per cent of the time, some 10 per cent of the time and a very large part of it only 2 per cent of the time. It would be quite possible at least to double the actual time-use of the equipment, not by increasing to 50 per cent the use of the few buildings and offices, but by increasing to 5 per cent time-use the enormously costly way and track.

The Question of Standards

This immediately brings up the question of standards. I can assume the railroad's full use of the hours of the year at 876, or 10 per cent of the whole time.

If this were done for the same volume of revenues, the equipment values could be reduced one-half, and instead of using $20,000,000,000 of equipment with an annual cost of $3,200,000,000 we should use $10,000,000,000 of equipment at an annual cost of $1,600,000,000 and an hourly rate of $1,827,500.

One-half the equipment working twice as many hours cuts the actual yearly cost in half and cuts the hourly rate to one-quarter. It means, were it possible, a yearly saving of $1,600,000,000.

It is of course not possible to reduce a horse to the size of a pony by starving him, even if he does travel only 5 miles a day. However big the horse, he must be fed, but in a new departure, I would invest in a pony and let him travel at least 10 miles.

The cost of a passenger train on the Kansas City, Mexico & Orient is about $2 a mile; an autobus in California carries as many passengers at a mile cost of 25 cents. The Kansas City, Mexico & Orient has an enormous and most idle investment in way, track and equipment; the California bus has no investment in way or road and a minimum investment in car.

We can now introduce standards with the formula:

$$\text{Actual: } t_a R_a = 438 \times \$7{,}300{,}000$$
$$\text{Standard: } t_s R_s = 876 \times \$1{,}827{,}500$$
$$\text{Efficiency: } \frac{t_s R_s}{t_a R_a} = 50 \text{ per cent}$$

It is evident that the best practice as to equipment is to use as little as possible, but to make it work all the time. The great world gain of using power-driven equipment is that it can work all the time, while man and animals can work only part of the time; but we have not yet outgrown the idea that, because man wants to rest two-thirds of the time, therefore the waterwheel should also rest two-thirds of the time, forever and irrecoverably wasting the unused water that goes over the dam instead of through the wheel.

Analysis of Personal Compensation

We next come to the leg of personal compensation. On the railroads the amount available for personal compensation is $2,500,000,000 yearly. The two factors are: T, the total hours of all men, and W, the compensation rate per hour.

The actual average compensation rate per hour was $0.76. We can expect of each man 2,400 hours in the year; $2,500,000,000 at $0.76 will pay for 3,300,000,000 hours, and, giving each man 2,400 hours, it would be possible to employ 1,375,000 men.

B. M. Jewell, president of the railway department of the American Federation of Labor, is reported to have stated that the annual minimum wage for a railroad employee is $2,133, or $0.90 an hour. This establishes the quality of the worker. Divide the available compensation fund equally between all workers, it would be limited to 1,125,000 employees. The actual total is over 2,000,000. Each man now supervises $10,000 worth of equipment. Each man to be worth $2,133 should supervise $18,000 worth of equipment.

Actual: $T_a W_a$ = 4,900,000,000 hr. at $0.76 = $3,724,000,000
Standard: $T_s W_s$ = 2,778,000,000 hr. at $0.90 = $2,500,000,000

Efficiency and Compensation

In bridge building, piano wire costs more than cast iron, but it carries a greater weight for each dollar paid. The $0.90 an hour man must supervise more per

dollar paid him (the machine does the work) than the $0.60 an hour man or the $0.20 an hour man.

$$\text{Efficiency: } \frac{T_s W_s}{T_a W_a} = \frac{2{,}778}{4{,}900} \times \frac{90}{76} = 67 \text{ per cent}$$

If the revenues are right, then the efficiency of the workers is only 67 per cent. If the men are actually 100 per cent efficient, then the revenues should be increased 50 per cent.

Caught between the devil of low revenues imposed by the Interstate Commerce Commission and the deep sea of high yearly compensation demanded by the unions and more or less forced by the President, the railroad executive should curtail the non-essentials of service until he can perpetuate and operate within his revenues.

Safety need not be waived, but frequency, speed, punctuality and comfort could each be abated.

Analysis of Material Costs

The next item is materials—QP. Q is the number of units as tons of coal and P is the price per unit. The general law holds good for materials: The better the quality the lower the end cost, as a less quantity is used.

This is particularly true of coal. Coal with 40 per cent ash has two-thirds of the heat units of 10 per cent ash coal, but it has no steaming value and is worthless.

Materials cannot be aggregated into a single unit, as some are measured by the foot, others by the pound, others by the gallon. We can, therefore, give for materials only the total cost QP = $1,443,000,000.

In industrial plants the efficiency of materials of operation and maintenance is rarely over 60 per cent, but we can assume it at 67 per cent, the same efficiency as the compensation.

$$\text{Actual: } Q_a P_a = \$1{,}443{,}000{,}000$$
$$\text{Standard: } Q_s P_s = \$942{,}000{,}000$$
$$\frac{Q_s P_s}{Q_a P_a} = 67 \text{ per cent}$$

Effect of Equipment on Compensation and Materials

We have, however, not yet finished. The standard equipment is only one-half the actual equipment, and such standard equipment might on the whole require three-quarters of the men and four-fifths as much material. This would bring down compensation efficiency:

$$\frac{T_s W_s}{T_a W_a} = 67 \text{ per cent} \times 75 = 50.25$$

and material efficiency:

$$\frac{Q_s P_s}{Q_a P_a} = 67 \text{ per cent} \times 80 = 53.6 \text{ per cent}$$

Applying the Above to Industry in General

American industrial activities, almost without exception, are overequipped and undersupervised; too much equipment of poor quality, too many men of insufficient competence, too many low-grade materials.

A Ford costs more per pound than a locomotive, a chauffeur averages more than a railroad employee and gasoline costs much more than coal, but t is more, T is less and Q is less and the autobus operates at $0.25 a mile.

The summary of the whole can now be made in millions:

$$\frac{t_s R_s + T_s W_s + Q_s P_s}{t_a R_a + T_a W_a + Q_a P_a} = \frac{\$1{,}600 + \$1{,}996 + \$771}{\$3{,}200 + \$3{,}724 + \$1{,}443} = 52.2$$

Necessity of Getting the Elements of Industry in Hand

Until the big essentials are well in hand, until all three legs are of the same length, until each leg is of the best material, heat-treated, it is inept to puzzle about details. If the equipment is basically too heavy and too expensive, if the horse is too big, there is little gain in cutting down on his oats. If owing to imperfect planning and inadequate supervision, more men are on the payroll than the revenues justify, the difficulty is not remedied by holding a stop watch over the supervisor. Unless there are standards as to every item of material, efficiency checks accomplish but little.

I have used the railroads to illustrate the value of the formula as a means of analysis. The railroads are a very large business, intimately interwoven with all other industrial activities.

How This Formula Is Applied

The formula has been used to reduce the cost of the staples in a periodical, and it has also been used to show the aggregated condition of all the industries in the United States; it is a formula of universal application.

Columbus, with three little caravels and a few men and a few tons of stores, in 3 months' time discovered a new world. Everything was small except the personality of Columbus.

It is not far fetched to believe that the duty and destiny of man is, with greater and greater competence, during shorter and shorter hours, to supervise larger and better equipment working continuously, and to use materials to 100 per cent of their possibilities.

There has been a bitter struggle, wasteful, unscientific and unnecessary, between the railroad executives and the railroad shop employees. Compensation during the last few years has taken too large a proportion of the revenues. The employees, having made substantial gains in rates of pay per hour, in reduction of hours and in strenuousness of work during the war period, are very reluctant to go back to former conditions. Railroad executives, knowing that compensation must be reduced in volume, have erroneously supposed that the only way was to reduce hourly rates. The workers, learning of proposed reduction in total compensation, have erroneously supposed that this must mean either reductions per hour, longer hours per day or harder work. On account of these misconceptions the clash occurred.

By the use of demonstrated methods, unknown both to executives and to shopmen, it would be not only possible but comparatively easy to reduce total compensation 33 per cent, yet not discharge a single worker, not reduce any hourly rate, not require longer hours, nor the exaction of greater effort per hour. By adopting the proved out methods, by co-operating to make them a success, the executives could have attained what is imperatively needed, if railroads are to endure—a reduction in total compensation costs—and the shopmen could have retained what they won during the war—higher rates, shorter hours, lessened effort, all desirable if civilization is to progress.

New York City.

Adsorption a Criterion of Corrosion

By B. D. Saklatwalla
General Superintendent, Vanadium Corporation of America

One of the most actively exploited fields of metallurgy today is the search after alloys, ferrous and non-ferrous, which will withstand corrosion. Experimenting has been practically the sole guide in this exploitation, and very many of the results achieved have been more or less accidental. We have known from times long gone by that certain alloys and metals have withstood corrosion for centuries, without our being able to attribute satisfactory reasons.

In our efforts to bring light into the subject and scientifically co-ordinate cause and effect, we have in recent years set up several theories as to the cause of corrosion. As such may be mentioned: the electrolytic, the film and the colloidal theories. Even with these at command, we do not seem to have made any great progress in understanding the phenomena. More so than the lack of understanding is the lack of a criterion or means of measurement of corrosion, which has hindered practical progress. Undoubtedly experimental investigation would be greatly accelerated and practical results more quickly achieved if such could be found, instead of relying upon actual service test as we are compiled to do at present.

It is remarkable that most of the so-called noble metals, especially of the platinum group, have the capability of taking up large volumes of gases. These gases are occluded not only in the pores of the metal in a loose condition, as in platinum sponge, but also are adsorbed on the surface and sometimes dissolved in the metal, forming a solution. It appears that the phenomenon of adsorption, whereby gases are condensed on the surface of a metal or of any other solid body, would have the tendency of imparting to that body surface activities, depending on the degree of adsorption. According to many investigators who have studied the phenomena of adsorption, it appears that every solid body in contact with a gas has the capability of condensing this gas on its surface. This condensation, in certain cases, reaches a magnitude corresponding to a pressure of several thousand atmospheres. Quincke advances the opinion that the film of adsorbed gas on the surface of a solid body shows a decreasing density, within the film, outward from the surface in contact with the solid body, and that at the surface of contact the density of the film corresponds to that of a solid body. Thus, the solid body will not be surrounded by the gas atmosphere in which it exists, but by a film of highly condensed gas constituting that atmosphere.

We are all aware of the fact that the velocity of a chemical reaction depends on the physical conditions of pressure, concentration, etc. The rate of interaction between the condensed gas of the film and the solid body will depend, therefore, on the density of the film. If a body has a high degree of adsorption, the condensation and consequent interaction velocity will be great and hence surface oxidation of the solid will take place quickly, probably instantaneously. We can thus see how a protective film will be formed immediately, which if it has the necessary physical qualifications of homogeneity, right thermal expansion, and so on, will prevent or slow up the velocity of further interaction. The presence of this reaction film will change the surface qualities of the body and hence its adsorption capability. However, if part of this protecting reaction film is removed by abrasion, the original metal surface with its adsorption capability comes again into play and instantaneously replaces the removed film. We have herein an explanation of the self-healing property of a protective film.

The corrodibility of a solid in a gas atmosphere will consequently depend on its capability of adsorbing this gas to a greater or less pressure, thus increasing or diminishing the velocity of surface interaction, hence being capable of instantaneously forming a protective film or not. Our experience in the past regarding metals such as platinum or palladium, which are non-corrosive and produce adsorbed surface gas films of a high degree of concentration, leads us to believe that the high interacting velocity and consequent nearly instantaneous production of the protective film is the essential factor in producing non-corrodibility. Hence the higher the adsorption capability the higher should be the non-corrodibility.

Another possibility of high degree of adsorption preventing corrosion is the fact that the high-pressure gas film, having the characteristics of a solid body, might act as protection itself without forming the secondary reaction protective film.

Owing to the high-density film being in contact with the solid another very important phenomenon may be brought into consideration—namely, diffusion. We might be able to explain on this basis how slight additions of another element to a metal, or difference in heat-treatment, or mechanical condition of the surface—i.e., whether strained or not—play a big part in accelerating or retarding corrosion. These influences might have a great bearing in changing not only the adsorption capability and consequently the rate of interaction chemically, but also of diffusion physically, between the solid and the condensed gas film. This rate of diffusion will undoubtedly have considerable bearing on promoting the speed of formation of the protective film.

As a remarkable example of the connection between adsorption and corrosion appears to be a fact mentioned by Dr. Balke in a recent address on tungsten and similar metals. He remarked that metallic tantalum was absolutely non-corrosive, having withstood the attack of boiling aqua regia for several hours, and at the same time mentioned the characteristic that it was capable of absorbing a very large volume of gas, thus being similar to palladium.

If the above contentions can be proved to be correct by experimental research, a definite relationship established between corrosion and adsorption, and an experimental method devised for measuring adsorption, we might have at command a simple and quick method of judging the adaptability of alloys and metals for corrosion. The method would be applicable as a criterion for atmospheric as well as submerged corrosion. It has been more or less firmly established that, for instance, in boiler water the dissolved gases are responsible for the corrosion and that by their removal corrosion can be checked. The study of submerged corrosion from the adsoption standpoint would therefore reduce itself to the study of the dissolved gases.

The above remarks are offered as a mere suggestion which may incite research in a new direction and may be of practical help toward solving the most imminent metallurgical problem now confronting us.

Pittsburgh Meeting, A.C.S., Section of Gas and Fuel Chemistry

EDITORIAL STAFF REPORT

THE Section of Gas and Fuel Chemistry of the American Chemical Society held its initial sessions at the Pittsburgh meeting with Dr. A. C. Fieldner of the Bureau of Mines as chairman and R. S. McBride, assistant editor of *Chemical & Metallurgical Engineering*, as secretary. The first session was a "Symposium on Combustion," under the chairmanship of Prof. R. T. Haslam, of Massachusetts Institute of Technology. Two other sessions were devoted to technical papers.

More than 300 persons were in attendance at the symposium as the Division of Industrial and Engineering Chemistry met with the Gas and Fuel group. The other sessions also developed a large number of worthwhile reports, as well as lively discussion, among the hundred or more persons in attendance. It was enthusiastically voted that the officers of the Society be asked to authorize the continuance of the Section for the New Haven meeting.

NEW KOPPERS OVEN DESCRIBED

The carbonization of coal was one of the most important general subjects considered in several of the papers. H. J. Rose described the new Becker coke oven, which has been developed by the Koppers Co., indicating the important increases in oven capacity which this new system of oven heating permits. As an example of the advance thus made it was reported that thirty-seven ovens of the new type will suffice to give the coke which would formerly have required fifty or more of the best previous type of ovens. This increase in speed of coking is the result of heating-flue construction. In the new oven the products of combustion of the heating gas pass over the top of the oven through cross-over flues and down the wall on the opposite side of the coal mass. Thus the horizontal heating flue, formerly the weakest structural feature of the oven, is greatly reduced in size.

The same author discussed the new electric oven method which has been developed at the Mellon Institute laboratories of the Koppers Co. for determining the byproduct yields which can be expected from any coal.

THERMAL EFFICIENCY OF A COKE OVEN

The thermal efficiency of modern regenerative coke ovens was discussed by Wilson, Forrest and Herty of the Massachusetts Institute of Technology staff, as a result of extended plant tests from which complete engineering data were obtained. There were included in this report: "First, discussion of data needed to show completely the thermal operation of a modern regenerator coke-oven battery; second, description of the experimental methods employed to obtain the needed data, together with a table giving experimental figures obtained; third, a table balancing total heat input against total heat output is given, with a discussion of this and a calculation of the efficiency of the ovens; fourth, a so-called sensible heat balance is tabulated, the net heat effect of the coking process is discussed and the relation between the sensible heat balance and the exothermicity of the conversion from coal to coke is indicated."

The authors conclude that the reactions involved in coking are exothermic to the extent of approximately 450 B.t.u. per pound of coal for the sample treated.

COAL CONSTITUTION AND ITS SIGNIFICANCE

A group of five papers by S. W. Parr, T. E. Layng and their assistants at the University of Illinois presented various phases of the problem of determining the constitution of coal and the relation of coal constitution to carbonization and to combustion of stored fuel. A study of solvents for the separation of coal into its type constituents has been made, with particular reference to the use of benzene, toluene and xylene. The investigators show that pyridine or acid solvents tend to react with the coal substance and do not give true indication of the constitution of the coal substance. Of the three neutral solvents, xylene gives the best and most complete removal of the bituminic material from the cellulosic material. The significance of these two groups of constituents is very effectively set out in the other papers.

During storage of coal there is no loss in the total B.t.u. of the fuel, but only a slight increase in B.t.u. per pound corresponding to the increase in weight which results from the absorption of oxygen. Mid-continent coals particularly have a large absorptive capacity for oxygen. As a consequence when the coal is burned in a furnace the oxygen is present intimately associated with the coal and goes off as carbon dioxide. This gas gives a blanketing effect over the fuel bed which deadens the fire and is the cause of the loss in efficiency and the practical plant troubles which follow the burning of mid-continent coal which has been a long time in storage.

By fractional decomposition these investigators have produced valuable data as to the behavior of the different constituents in the fuel. They have been able to carbonize separately the two groups of constituents and each of them when saturated with oxygen. For purposes of discussion the two groups of constituents are called bituminic and cellulosic. When these two constituents hold as much oxygen as they will combine with or absorb at low temperatures, they are spoken of as "oxygen saturated."

NEW THEORY OF COAL CARBONIZATION

From results upon these constituents the investigators propose a new theory of coal carbonization. Evidence shows that the bituminic bodies can often be oxygen saturated without destroying the utility of this constituent to bond the carbonized product into a good coke. It is this bituminic material which makes the coke coherent and gives rise to the cell structure. However, it appears that if the cellulosic material is oxygen saturated under many circumstances, the coking property is destroyed, even though a bituminic material of high bonding power be used. The evidence thus far available indicates a close co-ordination between experimental results and the practical experience with coals of different types. The authors conclude that the production of coke is not a simple matter of decomposition of organic matter. It is rather a destructive decomposition accompanied by cross-reactions which are largely affected by the oxygen content of the cellulosic group of constituents and to a lesser extent by the oxygen content of the bituminic group. The physical character of the final product depends upon the influence of the oxygen content more than any other single factor.

Parr and Layng, with assistants, reported on a

method for determining the softening point of coal, which consisted of heating the material in a tube while passing through it a stream of inert gas. When the coal softens, the particles of finely divided material coalesce and interrupt the flow of gas through the mass, evidenced by an increase in pressure at the inlet. When the heating has progressed further, the softened material loses its plastic form, becomes coked and is again porous to gas. By the time coking is complete the pressure required on the gas stream reaches a minimum again.

The application of this method to various types of coals gives a significant, distinctive set of results for each type. The authors indicate in this preliminary report that they hope to be able to distinguish between types of coals, the behavior of the types in storage, the behavior during coking, and to prophesy the relative value for coking from these characteristics of the raw fuels.

Products of Low-Temperature Carbonization

The coke produced from low-temperature carbonization of coal has in general been unsuited to general use because it is soft and subject to spontaneous combustion, making its storage and handling impracticable. Harry A. Curtis, of the International Coal Products Co., reported upon the Carbocoal process used by that concern for utilizing the coke produced by low-temperature methods. In this process, which has previously been described in *Chem. & Met.*, low-temperature coke is ground, briquetted after blending with pitch, and the briquets carbonized until a low percentage volatile product is obtained. The result is a dense, strong briquet which can be handled and burned almost exactly like anthracite.

In the report by Dr. Curtis are given the results of boiler tests of the unbriquetted low-temperature char, known in this process as semi-Carbocoal. These results show that attempts to burn this semi-coke on a Coxe stoker are impractical unless further prepared. The percentage efficiency obtained is rather low and the percentage capacity obtained from the furnace is not quite equal to that usually demanded in commercial practice. The heat absorption in the two cases reported is 59 and 63 per cent respectively, and the capacities obtained were 153 and 205 per cent of the rating.

Use of the low-temperature coke in powdered form in powdered fuel equipment gave slightly greater plant capacity and distinctly higher thermal efficiency, but the fuel is somewhat difficult to pulverize, so that it does not promise to be as widely useful in this form as when briquetted.

The methods used for examination of low-temperature coal tars were described by Prof. J. J. Morgan and R. P. Soule of Columbia University. The methods given were those given in articles which have already been reported by *Chem. & Met.*

Study of Coke Structure and of Sulphur in Coke

The character of coke as judged by its macrostructure is of great importance in valuing this material. A paper was given by H. J. Rose describing a system of impregnating the cut surface of a coke sample with a mixture of plaster of paris and magnesia in order that the delicate detail of structure can be brought out. Another novel method proposed is the direct ink printing from polished coke surfaces properly sectioned.

Physicochemical studies of the forms of sulphur in coke indicate, according to the report of A. R. Powell of the Bureau of Mines, that the sulphur exists in two distinctive forms: (1) a stable form which exhibits all the properties of a solid solution, and (2) free sulphur physically absorbed by the carbon. Coke may contain both of these forms in addition to some sulphur combined with iron as ferrous sulphide. At temperatures about 500 deg. C. the ferrous sulphide of coke oxidizes very readily in the presence of air to ferric oxide and free sulphur. This reaction seems to occur during the quenching of coke and explains the disappearance of ferrous sulphide from coke rather than any reaction which occurs during the coking process.

Discussion of Powell's work developed the suggestion that the same general scheme might perhaps be applied to nitrogen in coal and coke to gain an insight into the reactions that render it available as ammonia during coking.

Producer Gas From Powdered Coal

The making of producer gas from powdered coal in order to achieve higher over-all efficiencies from fuel use was discussed by R. T. Haslam and L. Harris of the Massachusetts Institute of Technology. Aside from the possibility of using a low-grade fuel, the use of powdered coal for the manufacture of producer gas would give a constant composition gas free from tar, thus being easily cleaned, and the producer would be flexible, rapidly handling changes in load up to full capacity. As a result of experimental work not yet completed a gas of 12 per cent CO and 7 per cent CO_2 has been generated. Theoretical and experimental considerations show that the main factors are, first, high temperature in the combustion chamber (1,100 to 1,300 deg. C.); second, air for combustion highly preheated (900 to 1,000 deg. C.); third, coal finely pulverized, and fourth, air and coal well mixed together and so maintained until the end of the reaction.

Gases in Brittle Boiler Plate

Steel samples from two boilers which had failed from caustic embrittlement have been analyzed by the Bureau of Standards. One boiler was several years old, the other comparatively new. Analyses for gases were made on samples representing the material from the center of the plate where no cracks had developed and from the edge of the plate between rivet holes where cracks had developed. There was but little variation between the combined nitrogen content of the center and the edge of the same plate or between the different plates.

The results for oxygen and hydrogen by the vacuum fusion method with antimony-tin alloy indicated 0.02 to 0.03 per cent oxygen and 0.0020 to 0.0030 per cent hydrogen in the plate.

Whiteware Studies in Pacific Northwest

The United States Bureau of Mines, in co-operation with the University of Washington, will undertake an investigation of the residual kaolins and feldspars of eastern Washington and northwestern Idaho for whiteware bodies.

The work which will be done will follow the lines of the kaolin investigations now under way at the ceramic experiment station at Columbus, Ohio, and will be performed in the new mines laboratory of the University of Washington at Seattle.

Graphitization in a Carbon Tool Steel

By Henry S. Rawdon and Samuel Epstein
Physicist and Associate Physicist, Bureau of Standards

In A recent article in this journal[1] a peculiar type of black fracture occasionally occurring in annealed carbon tool steel bars was described. Although the examination appeared to have been rather complete, no definite conclusion could be reached by the author as to the fundamental nature of the phenomenon or as to the reason for its occurrence. Advantage was taken of the offer to furnish a specimen for study, and the results of the examination of the specimen obtained in this way constitute the present article.

The sample was a short section of a 1⅛-in. bar; its fracture showed the same characteristic features as those previously illustrated in Fig. 1 of Mr. Green's article. In what follows, the light-colored muff will be called zone *a*, the black interior, *b*, and the light-colored pencil of material at the axis, zone *c*. The pronounced difference in structure existing across the section of bar was evident even in the rough-sawed face.

Microstructure

Fig. 1 is a micrograph illustrating the appearance of the material, "as received" polished but unetched. In each of the three zones isolated black spots were found; in zones *a* and *c*, which are very similar in appearance, the number of these was very much less than in zone *b*. In this one, the spots were arranged in a manner very suggestive of the crystalline structure of the metal.

The structure of the specimen as revealed by etching is shown in Fig. 2. Zones *a* and *c*, which appeared to be essentially identical, consisted of a ferrite matrix imbedded in which were numerous granules of spheroidized cementite together with the irregular black spots previously referred to. Zone *b* appeared to be practically free from cementite, either pearlitic or spheroidized, and showed only a ferrite matrix in which was the network of black patches noted in the unetched state. Presumably these black spots are graphite; they have the appearance of "temper" graphite such as results upon annealing rather than the flaky variety which separates directly from the alloy when in the molten state.

Heat-Treatment

The specimen was first given a "mild" hardening treatment: water quenched from 740 deg. C. (1,365 deg. F.), which is just above the beginning of the Ac transformation (according to Mr. Green's curves). It was put into the hot furnace, brought up to the desired temperature and held for approximately 5 minutes. After examination, the sample was given a more severe treatment: water quenched after being held for one hour at 775 deg. C. (1,427 deg. F.), which is considerably above the end of the Ac transformation.

TABLE I—BRINELL HARDNESS (1/16-IN. BALL, 15 KG. LOAD)

Treatment	Zone *a**		Zone *b**		Zone *c**	
Initial state	102	globular cementite and ferrite	67	graphite and ferrite	102	globular cementite and ferrite
First hardening (740° C.; 5 min.)	477	martensite and cementite	138	graphite, martensite and ferrite	225	troostite and globular cementite
Second hardening, (775° C.; 1 hour)	515	martensite	467	martensite and graphite	510	martensite
Annealed (775° C.; furnace-cooled)	120	pearlite and globular cementite	108	pearlite and graphite	127	pearlite and globular cementite

* In addition to the micro-constituents given, *a* and *c* also contained small amounts of graphite throughout.

In each case the outer light-colored layer, zone *a*, showed a martensitic structure. After the first or "mild" hardening treatment, a considerable amount of globular cementite remained scattered throughout the martensitic matrix (see Fig. 4). After the second quenching (Fig. 6), almost all of this had been dissolved in the matrix, thus accounting for the slight gain in hardness noted in Table I.

In zone *b*, the portion corresponding to the mossy black fracture, the structure varied considerably according to the severity of the hardening treatment. In Fig. 3 this zone was only partly hardened, each black (graphite?) spot acted as a center for the formation of martensite. Evidently these spots were the source of the carbon which dissolved in the ferrite matrix. The relatively low quenching temperature used and the very short sojourn at this temperature prevented complete diffusion of the dissolved carbon in the ferrite so that, in the quenched sample, portions of the unaffected ferrite matrix were still to be seen between the martensitic patches surrounding the black spots. This structural condition should properly be regarded as one of the transition stages through which the specimen, upon receiving the more severe treatment, passed. In this latter case (Fig. 5) no ferrite was found, the solution of carbon was uniform throughout the entire zone. It will be noted, however, that the black spots did not entirely disappear, but remained as a conspicuous feature of the microstructure.

Zone *c*, being at the center of the specimen, was not hardened completely by the mild quenching. This portion showed a troostitic structure and, as indicated in Table I, was much softer than the martensitic condition which resulted in this zone after the second or *severe* hardening treatment. Traces of graphite were found in the martensitic matrix of both zone *a* and *c* after both hardening treatments. These correspond to the isolated spots in these zones in the initial state of the material.

[1] Arthur W. F. Green, "Black Fractures in Carbon Tool Steel," *Chem. & Met. Eng.*, Aug. 9, 1922, p. 265.

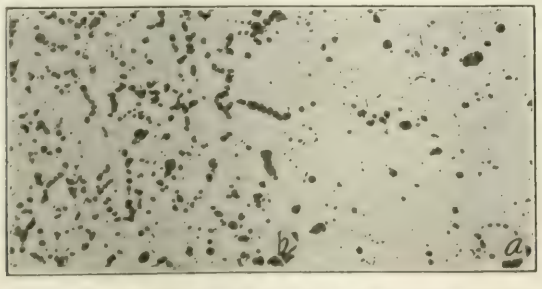


FIG. 1—UNETCHED SPECIMEN AT TRANSITION FROM BLACK TO LIGHT FRACTURE. × 100

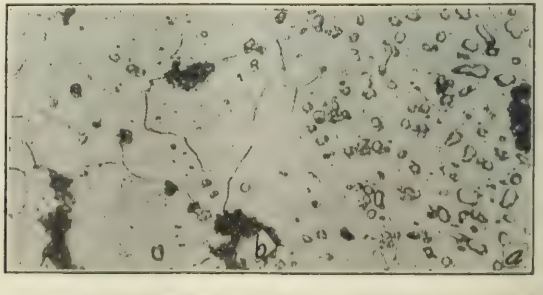

FIG. 2—SAME SPECIMEN AS FIG. 1, ETCHED WITH 5 PER CENT PICRIC ACID. × 500

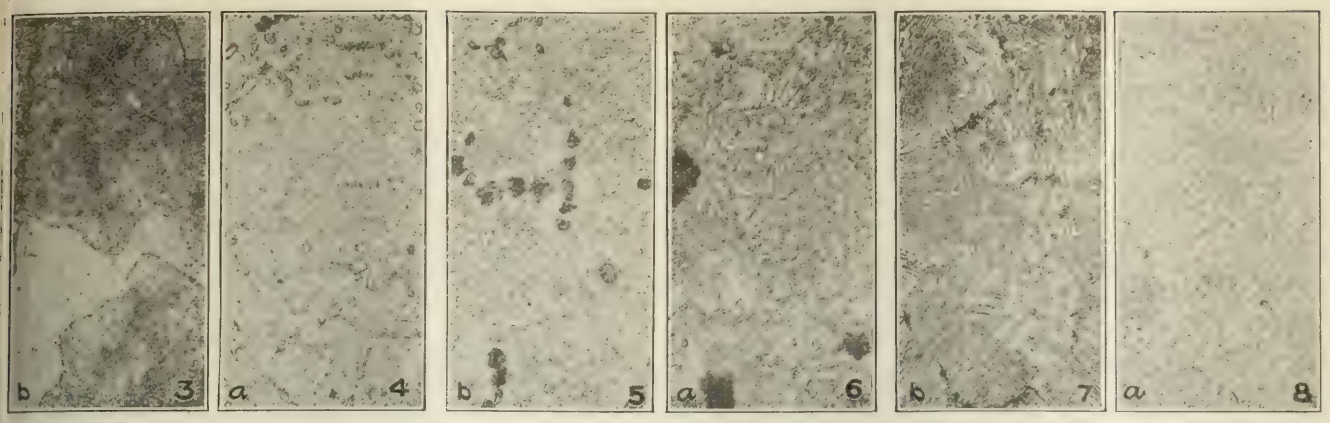

FIGS. 3 TO 8—STRUCTURE AFTER VARIOUS HEAT-TREATMENTS. ETCHED WITH PICRIC ACID. × 500

Figs. 3 and 4—Black and light areas after mild hardening.

Figs. 5 and 6—Black and light areas after full hardening.

Figs. 7 and 8—Black and light areas after annealing.

The hardened specimen was then annealed at 775 deg. C. and furnace-cooled. The resulting structure of zones *b* and *a* are given in Figs. 7 and 8. A comparison with Fig. 1 shows to what extent the condition and distribution of the carbon were affected by the series of heat-treatments described. In addition to the black areas, still to be seen, zone *b* showed considerable pearlite which formed from the carbon which dissolved upon heating the specimen above the Ac transformation, instead of the initial structureless ferrite matrix. As might be expected, zones *a* and *c* also showed a considerable amount of pearlite after the series of treatments instead of being completely spheroidized as in the initial condition.

Chemical Composition

The specimen, after the heat-treatment was completed, was analyzed chemically, the sampling being carefully done so as to keep zones *a* and *b* separate. (The small amount of material available did not permit of an analysis being made to represent the initial state of the steel.) The results are summarized in Table II.

TABLE II—CHEMICAL COMPOSITION*

Specimen	Carbon, Total	Carbon, Graphite, Per Cent	Manganese, Per Cent	Sulphur, Per Cent	Silicon, Per Cent	Nickel, Per Cent
Zone *a*...	1.20	0.30	0.15	0.024	0.07	not detected
Zone *b*...	1.24	0.45	0.15	0.023	0.08	not detected

* Analysis by H. A. Bright, associate chemist, Bureau of Standards.

So far as should be judged from the microstructure of the material in its initial condition, the outer layer, or zone *a*, did not contain much more graphite than was found by analysis. In zone *b*, however, essentially all of the carbon was in the graphitic form in the initial state of the material. After being subjected to our series of heat-treatments, however, the analysis indicated that the greater portion had reverted to the combined form. The other results of the analysis summarized above indicate no other feature of composition which throws any light on the unusual behavior of this specimen.

Nitrogen in Steel

A method for determining total nitrogen in steel has been under investigaton by the Bureau of Standards. It depends on the absorption in calcium vapor of all the gases evolved from the steel sample when fused *in vacuo*. The nitrogen is fixed as calcium nitride, which is then readily determined by solution in acid and distillation with sodium hydroxide.

Acetone as a Solvent for Bitumens, Asphalts, Animal and Vegetable Oils

An extensive investigation of the solvent properties of acetone is being conducted at the Mellon Institute of Industrial Research of the University of Pittsburgh, in order to ascertain its value as a commercial solvent. In the course of the work a number of bitumens and of natural and artificial asphalts have been tested. From the data obtained it has been concluded that the percentage of acetone soluble material decreases as the hardness of the asphalt or bitumen increases; it also decreases with the time of blowing, in the case of mineral rubbers. It was further noted that acetone possesses higher solvent properties for wood-tar pitch than various other commercial solvents. These conclusions, however, merely corroborate statements made by other investigators.

The acetone used in this investigation was obtained by the destructive distillation of calcium acetate and was of excellent homogeneity and uniformity. Its low specific gravity lowers its cost below or equal to other commercial solvents of high specific gravity, when purchased by the pound. Acetone is miscible with all ordinary commercial solvents and possesses the property of forming a homogeneous solution when added to two immiscible solvents.

A number of commercial and refined vegetable and animal oils have been tested and found miscible in all proportions with acetone at 25 deg. C. A small percentage of insoluble material was found in a few of the crude products, due, no doubt, to some foreign matter. The part soluble in these cases at 25 deg. C. is miscible in all proportions with acetone. The heavy greases and hydrogenated oils are only partly soluble at 25 deg. C., but are miscible in all proportions with acetone at its boiling point. A number of essential oils have also been tested and found miscible in all proportions.

The present grade of acetone obtained from calcium acetate is entirely volatile and therefore does not leave a residue in or impart an odor to the extract or extracted material. Its low boiling point permits the carrying out of extractions without danger of chemical changes in the product. Acetone is miscible in all proportions with and has a great affinity for water and thus acts as an excellent dehydrating agent. Acetone is less flammable than benzene, toluene, ethyl ether, gasoline, petroleum ether or pentane. Its physiological effects are negligible, if ordinary care is used in handling the solvent.

"You Know Me, Al Uminum"

As Presented at the Smoker of the American Chemical Society at Pittsburgh

AT EVERY MEETING of the American Chemical Society the local entertainment committee prepares "stunts" to be given at the smoker, when all dignity is relaxed and everyone becomes a boy again for the evening. The sixty-fourth meeting in Pittsburgh was no exception and that the efforts of the committee were appreciated was evident from the congratulations they received during the remaining days of the meeting.

One of the most amusing of the stunts was the presentation of a skit "You Know Me, Al Uminum," presented by the New Kensington Laboratory, Aluminum Company of America, written by H. V. Churchill. It is here presented in its entirety.

You Know Me, Al Uminum

Cast of Characters

AL UMINUM (A brilliant lightweight)....W. I. Sivitz
SILLY CON (A hard character).....E. L. McMahon
HYDRO GEN (A lady of volatile temperament) .....Emma Svenson
OXY GEN (A cosmopolite who loves 'em all).....Roberta Bridges

PROLOGUE

When Laugmuir writes for the learned *Journal*
Of concentric rings with an inner kernel,
He's miles ahead of the common herd;
The rank and file don't grasp the word.

So Ellwood Hendrick for *Chem. & Met.*
Sought to explain, but even yet
Lingers the question, persists the doubt,
If even Hendrick knew what 'twas about.

Our colloid friend from old Cornell
May know, but time alone will tell
If even dear wise Wilder D.
Does comprehend this theory.

Hildebrand of the Sunkist State
May understand, but it is fate
That gives him valiant aid;
Lewis tells him what was said.

William D. Harkins of isotope fame
Could yet enrich his well-known name
If he by hint or demonstration
Would make quite plain this lucubration.

Bill Lloyd Evans of Ohio State
Might cease his oxidation
And lend his ever trenchant pen
To mend our education.

H. P. Cady of old K. U.
Might cease his deep research,
But H. P., like the rest of them,
Has left us in the lurch.

Herty's too busy with colors and dyes
To waft to our ears the wanted replies;
He's been too busy at work on the tariff;
There's really more than he can take care of.

The cosmic urge to relieve the strain,
To make it simple, to make it plain,
Is the sole excuse for our present act
To now make plain what the others lacked.

The elements both great and small
Are sentient beings we can call
To tell their stories of life and love
As clear and bright as the stars above.

Al Uminum, a brilliant scout,
Loves all flappers round about,
While Silly Con, his foolish friend,
Has love affairs that never mend.

Two sisters come to see these men,
Two sisters of the name of Gen:
Oxy, the vamp, with vivid hair;
Hydro, her sister, almost as fair.

As said above, the learned men
Have sought ere this to wield their pen
In explanation of what it is
That makes each element just as is.

But now the truth will come to light
That elements may live and fight
And love and move, improve their soul
And move to their eternal goal.

Scene: Beyond the Chemical Veil

The curtain rises disclosing AL

AL (*soliliquizing*): Ah me! For years I've served my time in the kitchen. But if the world expects me to be happy *wearever* I may be, and whatever I'm called upon to do, the world is wrong. But then I'm ambitious and long for better things. I trust that when my time for better things has come I will have the best. Yes, better a hub cap on a Lincoln than to rattle and shake in the frame of a "car" I cannot well *afford.*

Enter SILLY CON

SILLY CON: Ah, milord, many times have I mixed in your affairs, and it is true that in time to come I will mingle once again, for methinks I'm happier in your affairs than when subjected to the heats and tempers of a career with F. Eric Iron, where usually my hopes are blasted, or at least withered in the fierce heat of the crucible of living. But enough of hopes. I just met the Gen family, the two sisters Oxy and Hydro.

AL: But tell me, where are they?

SILLY CON: They will be down here to call soon. They got mixed up with a couple of live ones from the Bureau of Standards, but the Washington boys couldn't give them Civil Service, so they shook them.

AL: Silly, old chap—you know I can't make up my mind about those girls or even their sister Nitro. When I am with Nitro Gen I would have none but her, and then a caustic word or two and we are thrust apart. She gives me a most unstable feeling. At that I'm losing weight, I fear; up at Harvard they say I weigh only 27, while the Bureau of Mines has claimed that I weighed only 26.8, but those fellows aren't always right. They talked about Hydro Gen too, but then Hydro Gen is not so dense as they claimed; she's a clever girl, and certainly fooled them just as I did.

SILLY CON: I have nothing to do with Nitro Gen, but what thinkest thou of Hydro Gen?

AL: Well, it's hard to say; she's always sticking with Oxy, which makes things rather damp, and only the other day Hydro said to me that when I really warmed up I was a most absorbing chap, but when my ardor died I was not at all so attractive to her.

SILLY CON: Well, for me, I'll say Hydro is much more attractive than Nitro.

AL: But, O boy! Little Oxy, she's the kind that always sticks around. Hot or cold, once with me she sticks. That's why I hesitate. When I'm apart from her I'm fairly neutral, but she is such a feminist that if we really wed I'd have to change the gender of my name like Maggie Sulf's brother did.

SILLY CON: What! Does that loose character have a brother?

AL: Sure! Years ago her elder brother Magnes married Oxy Gen. They since have been divorced, but while still married old Magnes was known far and wide as Magnesia.

AL: Speaking of Oxy Gen reminds me of a bit of gossip that may interest you. You are familiar with the publication that is always printing scandal about the elements?

SILLY CON: Do you mean the publication that is always telling what great discoveries are being made at the Mellon Institute, such as Pittsburgh fog dispellers, and——?

AL: Oh, no! I know what you mean. You have reference to the New York *Journal* or the New Kensington *Dispatch*. Now let me think. *Chemical Abstracts?* No! That is Organically too Complex. I have it! It is a McGraw-Hill weekly—*Chem. & Met.* Well, anyway, the story goes that one night Oxy Gen met that crude, unrefined Pete Roleum, and off together they went.

(SILLY CON *expresses surprise and horror*)

AL (*continuing*): The next morning Oxy Gen claimed an alibi. She said that man, Dr. James up there, enticed her by using a catalyzer.

SILLY CON: Ha! Ha! Ha!

AL: I tell you, Silly Con, it is contact catalysis which makes these blue-eyed flappers of Broadway wild—all of which makes Bancroft wilder.

(*A noise is heard without. Enter the two sisters. A general greeting occurs.*)

AL (*greeting girls*): I'm glad to see you. I miss your sister Nitro, but you know that girl ought to be careful. She should be taught to avoid the *Shoals* and beware the *Henry* or she will be fixed good and plenty.

SILLY CON: Al, you're lightweighted mentally as well as physically. Henry says he'll give Nitro Gen many a trip to the rural districts if Uncle Sam will give him the plants and a dam site more.

AL: Well, enough of Nitro. (*Turning to* HYDRO). And, Hydro, have you a rich auto maker to befriend you?

HYDRO: No, I'm pretty particular. Some auto makers I know of are not only interested in Nitro, but also in my cousin Hydro-Electric. Sort of Mormon-like, you know.

SILLY CON: Gee, Hydro Gen; you're easy to get up in the air.

OXY GEN: Isn't any one going to pay attention to me?

AL: Well, Oxy, old girl, we aren't neglecting you. But Silly and I are alike in one respect: You are so fascinating to both of us we are pretty cautious about too close contact. But that aside, Oxy, sing us some of that electron jazz stuff, but cut out that Brownian motion.

(OXY *sings*)

Al Uminum, with form so light,
Al Uminum, your face so bright;
Your valence three, while mine is two,
Your silv'ry grace makes me love you.

Al Uminum, I love you, I love you;
Each passing moment I'm longing for you,
You can't escape my caresses at all;
Your brilliant polish, your silv'ry finish,
With all my bonds I'll dull you, I'll dull you;
We cannot live apart, our love will live,
We have naught to forgive,
I love you, Al Uminum.

SILLY CON: By the way, Oxy, where is your brother?

OXY: Oh, you mean old Dry?

SILLY CON: Yes, old Dry Gin.

OXY: Why, he still has that old one on the brain. He's just full of that old Ethyl.

AL: Huh! Thought she was deported.

OXY: Technically yes, but practically no. She's quite elusive, you know, and she keeps slipping back. My goodness, Al, the names that girl goes under!

AL: I suppose I ought to be still about Ethyl, but after all I guess the Copper on this beat has the best reason to be still.

AL (*suddenly*): Oxy, I wonder if you'll let me whisper the old, old story once more; I don't care if we aren't alone.

OXY: Well, I suppose I'll have to get this over with.

AL: Oxy, I've tried both ways, with you and without you. In your presence I can't maintain my individuality.

OXY: Yes, I've heard that in my absence you were quite brilliant.

AL: And that isn't all. When I'm apart from you I am put to all sorts of tasks, in the kitchen, in the garage—I rather like that, though the engines are dirty—but when I am on those tasks I'm supposed to leave you strictly alone, and some way or other I realize when I am with you that I cannot exist without you. Oxy Gen, will you be mine?

OXY: Well, to tell the truth I'm not very coy, but if you will agree to share me with F. Eric Iron and old Silly Con, I will be yours in part.

AL: Sort of trial marriage, eh? Well, divorce is always possible, if things are not satisfactory. Maybe I'm giving up a lot, but I feel so isolated when I'm not with you. But, Oxy, I don't want to share you with others. You mention F. Eric Iron and dear old Silly Con, and truth to tell I've heard of others despite the fact we are natural affinities. If I alone can't have you, that settles it. Goodby.

OXY GEN: Oh, very well. It's all very well for you to talk that way, but mark my word, sooner or later I'll get you and have you for mine.

SILLY CON: Well, Oxy, I'm not so strait-laced as old Al. I'll just trot along and bask in your smiles as long as I can. No use sticking around, Hydro; you'd better trot along too.

OXY: Goodby, Al, old thing. Remember what I said. I've got old Silly, and I will get you yet.

AL (*slumps into chair*): What a common creature! She would tarnish whomever she would touch; even old F. Eric Iron has been looking rusty lately. However, life is that way. It is a Weidlein which keeps some of these elements from bringing home the Bacon. Oxy Gen seems to take old Al for a sucker, but that's the way with all Fishers. No matter how scientific they are or what the materials, they think old Al can be caught with the same bait used for F. Eric Iron or old Pete Roleum. Well, I wonder if Oxy is right. Will she finally get me? You know her list of victims is pretty long. But the solitary life for me, with just a few boon companions and not too much of them—old Copper, F. Eric Iron, Silly Con, Maggie Sulf's brother and a few others—but when old age comes creeping in and I am no longer on my mettle I will turn to Oxy Gen and yielding to her embrace cling fast till in some other phase I am reborn.

Properties and Manufacture of Aluminum-Silicon Alloys

By Junius David Edwards
Assistant Director of Research, Aluminum Company of America

SILICON is assuming importance as an alloying ingredient in aluminum. As a minor constituent, say in amounts of 1 per cent and less, it has always appeared as an impurity in aluminum alloys. As a major constituent in amounts up to about 15 per cent, it is capable of conferring very valuable properties upon aluminum alloys. Aluminum-silicon alloys have long been known, but their commercial development is comparatively recent.[1]

Aluminum-silicon alloys may be grouped in two classes. What may be called the "normal alloys" are made by melting silicon (or a rich alloy of silicon and aluminum) with aluminum, and casting in sand according to the usual foundry practice for aluminum alloys, except that in most cases all chills may be omitted. They are characterized by a relatively coarse crystalline fracture (Fig. 1), especially when the silicon is high. When

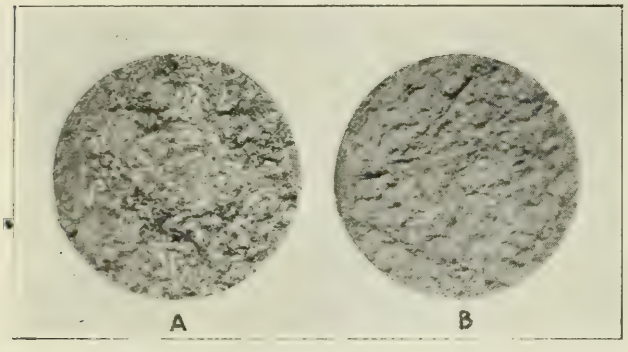

FIG. 1—ALUMINUM-SILICON ALLOY
(12.5 per cent silicon)
A—Shows relatively coarse crystalline fracture of **unmodified alloy.**
B—Shows very fine grained fracture of modified alloy.

the iron content is also high, excessively coarse-grained structures are produced. When polished and viewed under the microscope, they reveal the presence of silicon as relatively large plates and needles in a matrix of aluminum.

What are known as the "modified alloys" are given a special treatment in the molten state immediately before casting. The Aluminum Company of America's process[2] of modifying aluminum-silicon alloys consists in the addition of very small amounts of metallic sodium to the molten alloy a short time before casting. The modified alloy exhibits an exceedingly fine-grained fracture (Fig. 1); the microscope shows the silicon to be present as very finely dispersed particles;[1] the silicon particles are sometimes so small as to be resolvable with difficulty even at very high magnifications.

The modified alloy largely reverts to the normal alloy on remelting, so that to secure a completely modified alloy, the molten metal must usually be re-treated each time before casting.

The aluminum-silicon alloys possess a combination of desirable properties which fit them for many uses, especially for the production of difficult castings, involving both thick and thin sections. Some of their most useful characteristics fall under the term of "casting properties." They flow readily, may be cast into very thin sections without cracking, and are quite free from shrinks and the porosity which is not uncommon in some other aluminum alloys, so that they are "water-tight." These same good casting properties are found in both the normal and modified alloys, so that the use of the modified alloy is, in general, only indicated where its increased strength and ductility will prove advantageous. The proportion of silicon to be used in any alloy will depend on its particular application. In general, a somewhat higher proportion of silicon can be used in the modified alloy than in the normal alloy. This is due to the fact that the process of modification raises the apparent eutectic composition considerably above its normal figure (11.5 per cent silicon), and changes what would have been relatively large particles of excess silicon (in alloys containing over 11.5 per cent silicon) to very finely dispersed particles of eutectic silicon.

The modified alloys should contain from about 8 to 15 per cent silicon; 12 per cent silicon makes a good alloy. The normal alloys may contain from 4 to 10 per cent silicon; 5 per cent silicon has been found to make a very satisfactory alloy for sand castings.

In the following paragraphs will be found values for a number of the physical properties of aluminum-silicon alloys, which are pertinent to their commercial application.

Density

Silicon is lighter than aluminum; its density is about 2.4, as compared with 2.7 for aluminum. The alloys have densities intermediate between these two values. The 10 per cent silicon alloy will have a density of approximately 2.65 grams per c.c. There is a tendency for the modified alloys to be slightly lower in density than the normal alloy, but the difference is not significant. The 10 per cent silicon alloy is 7 to 8 per cent lower in density than No. 12 alloy (8 per cent copper), and weighs approximately 166 lb. per cu.ft.

Expansivity

The splendid casting qualities of the aluminum-silicon alloys are in part the result of their relatively low shrinkage. The pattern shrinkage is the same as for other aluminum alloys—namely, $\frac{5}{32}$ (0.156) in. per foot. The aluminum-silicon alloys have a very much smaller crystallization shrinkage than either No. 12 alloy or pure aluminum. Pure aluminum contracts between 6 and 7 per cent in volume on solidifying; this contraction in volume results in the formation of a cavity or pipe. This crystallization shrinkage or contraction is reduced to 4 per cent or lower in the 12 per cent silicon alloy. The thermal expansivity of the 10 per cent silicon alloy is about 0.000021 per deg. C., in the range 20 to 100 deg. C.

Tensile Strength and Elongation

The modified alloy has considerably greater strength and ductility than the normal alloy. Typical results for various alloys are given in the following tabulation:

STRENGTH AND DUCTILITY OF ALUMINUM-SILICON ALLOYS AS CAST IN GREEN SAND

Composition	Character of Alloy	Tensile Strength, Lb./Sq.In.	Elongation, Per Cent in 2 In
Silicon 5%	Normal	18,000	5-6
Silicon 8%	Normal	19,000	4
Silicon 8%	Modified	24,500	12
Silicon 13%	Normal	21,000	2
Silicon 13%	Modified	28,000	8

Better or poorer results than the above can be obtained with varying conditions. The proportion of iron

[1] A concise and authoritative account of their history was printed in *Chem. & Met. Eng.*, vol. 26, p. 750 (April 19, 1922).

[2] U. S. Pat. 1,410,461, J. D. Edwards, F. C. Frary and H. V. Churchill.

in the alloy should be strictly limited for the best result. Iron forms with silicon an iron silicide, which appears as needles in the microstructure. The modifying treatment has little refining effect on the particle size of this constituent, and its presence tends to reduce the ductility. The alloy as cast should preferably contain not over 0.5 to 0.6 per cent iron. The copper content of the modified alloy should also be held below about 0.8 per cent if the highest combination of strength and ductility is desired.

Electrical Conductivity

The modified aluminum-silicon alloy containing about 12 per cent silicon will have an electrical conductivity of about 34 per cent referred to the International Annealed Copper Standard; this conductivity is only slightly higher than that of No. 12 alloy. The conductivity of the normal alloy is usually somewhat lower than that of the modified alloy.

Thermal Conductivity

The thermal conductivity probably corresponds to the electrical conductivity—that is, it is slightly higher than that of No. 12 alloy. This statement is apparently confirmed by observations recently recorded in the literature.

Resistance to Corrosion

The aluminum-silicon alloys are quite superior to No. 12 alloy in their ability to resist most types of corrosion. This property is shared equally by the normal and modified alloys. The alkali metal added to effect conversion of the alloy to the modified form is present in such minute amounts that it exerts no apparent effect on the resistance to corrosion.

Machining Qualities

The aluminum-silicon alloys are not quite so easily machined as No. 12 alloy. They exhibit a very pronounced tendency to drag under the tool. Particles of excess silicon, if present, add greatly to the difficulty of machining or polishing, as they tear out readily, and are exceedingly hard and scratch the soft aluminum readily. Normal alloys containing less than about 11.5 per cent silicon will contain no excess silicon. Above this proportion, they may contain excess silicon unless completely modified.

Production of Castings in the Foundry

For the preparation of the alloy, the rich silicon alloy supplied by the Aluminum Company of America should be used.[3] This alloy contains approximately 20 per cent silicon, has a melting range of about 1,070 to 1,290 deg. F. (577 to 700 deg. C.), and dissolves readily in aluminum at temperatures not over 1,300 deg. F. High-grade ingot should be used in diluting the rich alloy to the required composition, so as to keep the iron content to a minimum. This point is mentioned again, for the highest strength and ductility are developed only when the iron is 0.6 per cent or under, and the rich silicon alloy, although made from a specially pure grade of silicon, may unavoidably contain considerable iron.

[3]It looks like plain advertising to state that "for the preparation of the alloy the rich silicon alloy supplied by the Aluminum Company of America should be used," and if it were just advertising such a statement would be out of place in this article. However, our experience has demonstrated that to obtain the results described, it is necessary that the alloy shall be prepared from that particular rich alloy. There are sound metallurgical reasons for this statement also, as the method of manufacture produces an alloy which has already been modified and which gives superior results in the subsequent alloying and casting.

Process of Modification

The Aluminum Company of America's process of producing modified alloy castings consists in adding to the aluminum-silicon alloy a very small percentage of metallic sodium. The correct amount of sodium to treat a definite weight of aluminum-silicon alloy is supplied in a sealed aluminum capsule. The aluminum-silicon alloy is heated to a temperature of about 1,500 deg. F. and the proper number of aluminum capsules placed in a phosphorizer, which is plunged to the bottom of the crucible. The phosphorizer, so called, is an inverted cup, formed from a graphite crucible or a short piece of iron pipe and held on the end of an iron rod; the iron parts are coated with graphite or lime wash to prevent attack by the aluminum. The aluminum capsules are wedged into the inverted cup and melt when plunged into the molten alloy. The melted sodium then escapes slowly into the alloy through a series of small holes in the sides of the cup near its top. The sodium diffuses through the metal, and a certain amount rises to the surface and burns. The liquid alloy should be kept up to a relatively high temperature until all of the sodium has disappeared from the phosphorizer. The operator can tell when all of the sodium has dissolved by lifting the phosphorizer until it comes in contact with the air. If there is no sodium flame, the modifying process is complete. When the modifying operation has thus been completed, the metal is skimmed. Stirring is not advisable, as it facilitates the oxidation and loss of the contained sodium. Skimming, however, should be performed with great care. When the metal has reached the proper pouring temperature, it can be cast in the usual way. As low a pouring temperature as possible should be employed. Too long a period should not intervene between the time of treatment and the time of pouring, if complete modification is desired. The metallic sodium is lighter than aluminum and relatively insoluble in it, so that it is gradually lost from the molten metal on standing. The modified alloy exists in a potential form only, in the liquid state; the actual modification results from the modified mechanism of solidification in the presence of the sodium.

Requirements for Electrical Mica

Requirements for mica for electrical purposes relate to dielectric strength, heat resistance and flexibility, states the Bureau of Mines in Serial 2,357. All good electrical mica is sufficiently resistant to heat for ordinary electrical equipment and this quality is, therefore, rarely specified. Specifications for dielectric strength vary for different uses and with different consumers for similar uses. Navy Department specifications call for a dielectric strength of not less than 25,000 volts for each $\frac{1}{32}$ in. thickness. Mica has such a high dielectric strength that failures most commonly occur in defective spots. It is very important, therefore, in selecting material where high dielectric strength is required that the mica be given a careful visual examination so that all defective sheets may be rejected.

Department of Agriculture Exhibits

During the fiscal year 1921-22 exhibits by the United States Department of Agriculture were shown at about 70 fairs and expositions held in thirty-nine states and in the District of Columbia. These figures include many occasions for which special exhibits were prepared.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Electrolytic Refining of Tin—F. C. Mathers, of Bloomington, Ind., patents a modification of the Whitehead process (Patent 1,157,830; Oct. 26, 1915) whereby the electrolyte may hold as little as 2 per cent of tin, instead of 6, and 5 per cent of hydrofluosilicic acid, instead of 15 to 20. Furthermore, the amount of H_2SO_4 carried may be largely increased. Dense, coherent deposits, analyzing 99.9 per cent tin, may be had when electrolyzing impure Bolivian anodes, when to this electrolyte is added a fraction of 1 per cent of cresylic acid residues or mixtures of meta-, ortho- and para-cresol. Some unknown substance, which is common to these hydrocarbons, is thought to be responsible for the peculiar action of the electrolyte specified. (1,397,222; assigned to American Smelting & Refining Co. Nov. 15, 1921.)

Sulphonating Hydrocarbons — A method of sulphonating the aromatic hydrocarbons which is said to increase the efficiency of the sulphonating operation by decreasing the amount of sulphones formed during the process has been patented by A. R. Grob and C. C. Adams, of Wilmington, Del., and assigned to E. I. du Pont de Nemours & Co. The feature of the process is the use of liquid sulphur dioxide as a medium for the sulphonation process. The excellence of sulphur trioxide as a sulphonating agent is due to the fact that it is very active chemically—much more so from the standpoint of sulphonation than sulphuric acid or any other sulphur compound—and also because its sulphonates by direct addition without the formation of water. Its greater activity enables a sulphonation to proceed with less excess acid and without the employment of very high temperatures, which would have a tendency to cause decomposition. By preventing the formation of water, the isomeric rearrangement of the molecule is obviated. When sulphur trioxide is used undiluted, it acts too vigorously, making the reaction difficult to control and causing a greater degree of sulphonation than desired. It may cause charring and oxidation of the compound. It is usually diluted with sulphuric acid, but this makes a strong dehydrating mixture which favors decomposition, especially when oxygen is present in the compound, and also promotes the formation of sulphones. It is claimed that by diluting the sulphur trioxide with liquid sulphur dioxide, the action of the former can be made less vigorous and the reaction more easy to control. The presence of sulphur dioxide, which is a strong reducing agent, lessens oxidation. Finally, since the dehydrating action is minimized by using sulphur dioxide instead of sulphuric acid as a diluent, less decomposition and sulphone formation is encountered. The process is carried out by mixing a liquid sulphur dioxide solution of sulphur trioxide with a liquid sulphur dioxide solution of benzene, maintaining the resulting mixture under pressure until the desired degree of sulphonation has occurred, the temperature being maintained at about 0 deg. C. during the addition of the sulphur trioxide, and then permitting the temperature to rise to about 30 deg. C. under pressure. (1,422,564. July 11, 1922.)

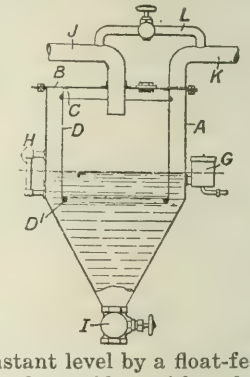
Pulp Washer—Carlton H. Allen, of Millinocket, Me., has assigned half rights in a modified pulp-thickening machine to the Great Northern Paper Co. The inventor has attempted so to design the apparatus that it will have a greater capacity for a given area of screening or filtering surface, produce more uniform results and be more easily repaired than machines heretofore used. The apparatus comprises a rotary drum with sixteen faces, covered with a wire cloth filter. The drum is supported on trunnions in a closed box so that it runs entirely submerged in the "stuff." The casing is constructed in such a manner that in two points on its circumference of the drum, contact is made between drum and casing by the layer of thick slushy pulp adhering to the filter. The pulp is discharged continuously from the casing between these two points of seal. The filtering is speeded by the hydraulic pressure maintained on the drum by the thin pulp supply. (1,421,364. July 4, 1922.)

Beryllium—A process for the extraction of beryllium from its ores which involves the reduction of the ore to the silicide or the carbide and a subsequent treatment with hydrochloric acid gas to form the volatile chloride of the rare metal is covered in a specification granted to Louis Burgess, of Bayonne, N. J. The ore is ground and mixed with a suitable hydrocarbon bonding agent, preferably a high-melting petroleum pitch which on heating will yield approximately 50 per cent of carbon. The mixture is placed in an electric furnace and is reduced by the heat of an arc, the operation being conducted under about 30 lb. pressure. The resulting product is ground and subjected to a treatment with hydrochloric acid gas at a temperature of about 450 deg. C. The beryllium chloride is volatilized by the heat and condensed in a series of chambers maintained at temperatures below that at which beryllium choride sublimes, but above the boiling or sublimation temperature of aluminum chloride or zirconium chloride, or approximately 200 to 250 deg. C. The beryllium chloride is then converted to the oxide by treatment with water. The second specification covers the application of the same idea to the metallurgy of zirconium. The chloridizing reaction is exothermic, and it is said that a very complete reaction is obtained by introducing the silicide or carbide as a powder into an atmosphere of hydrochloric acid gas. (1,418,527. June 6, 1922.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Gas Scrubber—Producer and like gas is simultaneously cleansed and enriched by passage through a porous screen fed with liquid by capillary action. The apparatus shown comprises a casing *A* tapered at the bottom and covered with a gas-tight lid *B* to which an annular flange *C* is secured, the flange having secured to it a wick or filtering cloth *D* weighted with a leaden rod or wire *D*¹. The lower edge of this wick dips into a bath of oil maintained



at a constant level by a float-feed chamber *G* and provided with a level indicator *H*. The gas entering by a pipe *J* passes through the wick, being thereby cleansed and enriched, and escapes by a pipe *K*. A bypass *L* is provided. The casing may be heated by engine exhaust gases or jacket water passed through a jacket. Impurities are removed through a valve *I*. A perforated ring of pipe may be disposed in the upper part of the casing in communication with the outlet *K*, or an annular chamber may be formed by the provision of a perforated disk fitted at right angles to the flange *C*. (Br. Pat. 181,102. T. G. Tulloch and D. J. Smith, London. Aug. 2, 1922.)

Calcium Hypochlorite — Calcium hypochlorite is rendered stable by mixing it, in the dry state, with purified sodium chloride, free from magnesium chloride and other hygroscopic impurities. The proportions are such that the product contains at least 10 per cent of active chlorine. The mixtures can be moulded into shape. (Br. Pat. 181,153. Chemische Fabrik Griesheim-Elektron, Frankfurt-on-Main, and H. Reitz, Bitterfeld. Aug. 2, 1922.)

Sulphuric Acid—In the manufacture of sulphuric acid, a stream of cold acid is made to trickle permanently over the whole inner surface of the walls of the lead chambers or towers for the purpose of protecting them from corrosion. Preferably chambers are constructed as cylinders or reversed truncated cones, cold acid being directed on to the walls by a turbine of resistant material placed axially near the top of the chamber and fitted with jets or wings to ensure the wetting of the whole inner surface. Nitrous vitriol may be introduced into the chamber in the same way. (Br. Pat. 180,546. E. A. Gaillard, Barcelona. July 19, 1922.)

Book Reviews

TECHNOLOGY OF CELLULOSE ESTERS. By *Edward Chauncey Worden, Ph.C., B.S., M.A., F.C.S.* Volume I, in five parts. Part 1, cxxv + 664 pp.; Part 2, cxvii + 902 pp.; Part 3, cxvii + 810 pp.; Part 4, cxvii + 710 pp.; Part 5, 623 pp.; 296 illustrations. New York: D. Van Nostrand Co., 1921. Price $40.

Work, for the night is coming,
When man's work is done.

This is the quotation selected by the author for the flyleaf of Vol. I, Part 1, of the above series, and regarded from the point of view of the magnitude of the task undertaken it cannot but be considered an appropriate one. Some idea of the labor involved in the preparation of the treatise may be gleaned from the fact that the accumulation of the entire material has extended over a period of 25 years and includes about 335,000 references relating to the work of 55,000 separate investigators and to 58,000 patent topics. In the words of the author, "The aim of the work is to present the entire subject of the combinations of normal and modified cellulose with the acidyl and alkyl radicles . . ."

The first volume (under review) consists of five parts—viz., Part 1, embracing the raw materials, cellulose, starch and cotton; Part 2, dealing with the manufacture of nitric, sulphuric and mixed acids; Part 3, describing the history, theory, chemical and physical properties of cellulose nitrates and other nitrated carbohydrates; Part 4, giving the synoptical development of the cellulose industry; and Part 5, containing the patent, name and subject index of the entire volume.

Volume I aims to give a complete review of cellulose, starch and cotton, and it is difficult to think of any branch of the subject to which reference is not made in some portion of the work, although it may not always be an easy matter to locate it. For example, the reader in a search of the literature on the decomposition of cellulose by bacteria will find, on consulting the index, only a single reference and this an incorrect one. If he should then recall that one of the important papers on this subject (published in 1912) relates to the intermediate formation of cellobiose as one of the degradation products and should search the index under this heading, his efforts would again be fruitless. It would be necessary for him to recall the name of the author—viz., Pringsheim—before he would be able to obtain the information desired. It may also be mentioned that while attention is drawn in the text (p. 339) to the fact "that in the breaking down of the cellulose molecule by the aid of bacteria no intermediate compounds have been isolated" the accepted work of Pringsheim proving the contrary—viz., the intermediate formation of cellobiose and dextrose—is quoted only as a note (p. 343).

A question of general interest is that of the manufacture of a highly purified cotton, and many chemists will feel that the method of Robinoff and Bay (as developed in the laboratory of Schwalbe) referred to casually (p. 144) in the discussion on hydrocellulose is a better one than that quoted by the author (p. 26).

No reference in the text could be found to the interesting work of F. Bergius on the action of water on cellulose at high temperatures and pressures, but on consulting the index it was located in a footnote under the heading of "Maltol" (!).

Part 2 contains a comprehensive review of the manufacture of nitric, sulphuric and mixed acid, and provides a wealth of information regarding the source of raw materials, manufacturing processes, analytical data, etc. Unfortunately the footnotes quoted suffer from a failing which is apparently common to the entire work—namely, the inclusion under a given heading, for example, nitric acid, of a large number of references, many of which do not refer to this specific subject, although they do refer to the nitrogen industry. It is to be regretted that it was not found possible to insert in the footnotes some kind of secondary classification through which their accessibility and usefulness might have been much increased.

There are also occasional statements in the text which are likely to mislead, as for instance the one quoted on p. 746 to the effect that "The du Pont company heats by means of an oil bath," the presumption being that this is an actual operation, whereas it merely represents a patent taken out in the name of F. T. Beers and assigned to the du Pont company.

On p. 988, Fig. 86, there is apparently a mistake in the title of the illustration, this reading "Jensen Nitric Acid Concentrating Plant," while in fact the drawing is from a patent granted to F. C. Zeisberg of the du Pont company on "Nitric Acid Concentration."

Part 3 takes up the historical development, theory and practice of nitrocellulose manufacture and undoubtedly represents the most complete bibliography of the subject in any language. It also contains a review of the preparation and properties of the nitrated carbohydrates, a description of the layout and construction of a modern guncotton plant and of the analytical data relating to cellulose nitrates.

In Part 4 the author states (p. 2378), "The subject matter of this section is intended as a general epitome of the more important and noteworthy of the technical advances of the cellulose esters . . ." It includes a description of the organic liquids used as solvents for the esters and the manufacture and use of synthetic and natural camphor, the greater part of the volume, however, being devoted to an account of the varied uses to which the cellulose esters have been applied in the industry.

Of Part 5 the author states in the introduction, "The belief formerly held by us that the index was the most important part of a technical work has long since become a conviction, many an otherwise valuable book having been materially impaired by the omission, incompleteness, brevity or faulty construction of the index—in our judgment without question the most important and painstaking portion of a work of this character"—an opinion in which the reviewer heartily concurs.

It is impossible to peruse the index without at once realizing the incredible amount of time, thought and actual drudgery which has been spent upon it by the author and his assistant, Mr. Rutstein. Technical chemists will be especially grateful for the valuable patent compilation, in itself a work of no small proportion, and readers of the volumes will doubtless consider it a duty to acquaint the author with any slips or omissions.

It is of interest that he states in the introduction, p. lx, "It is but necessary to glance at the 'Index of Names' in this volume to realize how essential it is that at least the initials of writers should always be given." Unfortunately, this idea is not always carried out, as for example in the case of the two authors designated under A. Hill, one of which should read A. J. Hill.

The reviewer is compelled to admit that the treatise contains many grammatical errors.

If considered as an authoritative work, it would be subject to criticism, but regarded from the point of view of a bibliography of the subject, it represents the most complete in existence and will undoubtedly take its place as part of the indispensable equipment of all workers in the field of cellulose chemistry.

No one can peruse the volumes without being impressed by the magnitude of the task undertaken and experiencing a feeling of gratitude toward the author. Add to this his statement in the introduction that "the entire cost of the preparation, printing and publishing of this work has been met by the author personally from his private funds," and it will be possible to realize to some extent the obligation under which he has placed his fellow chemists.

HAROLD HIBBERT.

Dye Embargo Dies Hard

Strenuous Attempts to Obtain Extension of Dye and Chemical Restrictions Fail—Will Attempt Readjustment of Rates at Next Session of Congress

WITH a quietus put upon the proposal to extend the dye and chemical embargo through failure of the Senate Finance Committee to report the resolution favorably and refusal of House leaders to act before this had been done, a definite move has already been started to attempt to get Congress to adjust the tariff rates on coal-tar products and synthetic organic chemicals by means of a separate bill.

The death of the proposed temporary extension of the dye and chemical control act was rather unexpected, in view of the letter of Secretary Mellon stating that the Treasury Department lacked the necessary machinery to administer tariff rates on coal-tar products on the basis of American valuations.

Finance Committee Rejects Proposal

The Senate Finance Committee considered the resolution proposing extension of the embargo for 3 months on three occasions, twice at a meeting Wednesday, Sept. 20, and again at a meeting Thursday, Sept. 21. The first vote in the committee was 5 to 3 against a favorable report. The resolution then was amended to read 60 days instead of 3 months and because of the small attendance at the committee meeting, it was decided that Senator McCumber should cast the votes of the absent Republican members, and Senator Simmons the votes of the Democratic absentees. On this vote there was a tie, 8 to 8, with Senators Smoot and LaFollette voting with the Democrats in opposition. It was generally considered that this tie vote ended the matter, but on the following day it was revived before the committee with fourteen of the sixteen members actually in attendance. Senator Reed of Missouri raised the point of order that inasmuch as this resolution affected the revenue of the country, it could not constitutionally be considered by a Senate body until it had been acted upon by the House. This point was sustained by a vote of 7 to 5, with Senators Smoot, LaFollette, Dillingham and Watson of Indiana joining the three Democratic members present. This ended the effort.

The House Ways and Means Committee had handled the resolution, which was introduced in that body by Representative Tilson, rather gingerly, and reported it favorably by a vote of 10 to 7, with three Republicans, Representatives Green, Watson and Young, voting with four Democrats against the report. Following this action, Republican members of the committee sent word to Senate leaders that they would not press the resolution in the House unless it first had been passed by the Senate, as they did not wish to be put in a position of attempting to push it through the House while there was a possibility that the Senate might not act favorably. Therefore no action further than this report was taken in the House.

Smoot Suspicious of Motive

In explaining his attitude, Senator Smoot declared that the Treasury Department had had an organization to administer the licensing system of the dye and chemical control act and that he thought this could easily be transferred and adjusted to administer the American valuation tariff rates. He would have been willing for a 60-day extension, he said, if he could have received assurances that no effort at the next session of Congress would be made to extend the embargo further. Most of the other leading opponents of the embargo had virtually agreed to withhold opposition from the resolution if the time were reduced to 60 days. Senator Wadsworth, sponsor of the resolution in the upper chamber, stated that he himself would not ask further extension at a later session of Congress but that he could not be understood as attempting to control the acts of other Senators.

Mellon Asks Time for Organization

In his letter regarding the administrative difficulties attendant upon inclusion in the tariff bill of American valuation on coal-tar products, which was addressed to Senator McLean in response to an inquiry from the latter and dated Sept. 7, Secretary Mellon asked that a 90-day extension of the dye and chemical control act be given so that the Customs Service might organize to administer these rates. The Secretary also asked that domestic manufacturers be compelled to file statements of their products with the

A.C.S. Committee Invites Criticism of Society Policies

Powers of Committee on Procedure Enlarged to Include All Matters Relating to Management and Policy

The committee of the American Chemical Society which was appointed at the Birmingham meeting to consider the advisability of changes in society procedure is endeavoring to collect all the specific questions which should be considered in this connection. The powers of the committee have been enlarged, by action of the advisory committee, to cover any subject relating to the management, procedure or policy of the American Chemical Society in order that there will be no doubt of the thoroughness of the inquiry. It was also voted to appropriate funds necessary for the proper functioning of this committee.

The vote passed at the meeting of the advisory committee in Pittsburgh Sept. 4 follows:

> Resolved, That the powers of the committee on progress in society procedure, voted at the Birmingham meeting, be enlarged and that the committee be requested to consider and report upon any subject relating to the management, procedure or business policy of the society requested by any local section, or which in their judgment should be investigated, in order that the society may have full confidence in the efficient handling of its affairs by its elected officers.
>
> Be it further resolved, That the committee on national policy request the directors of the society to appropriate, if possible, funds not exceeding $500 to enable the committee to meet together or to visit, as a committee, such offices of the society as they deem desirable, in order that their inquiry may have unquestioned thoroughness.

The committee is anxious to have the ideas of the various sections on specific questions which should be considered under this new scope. It is hoped that the criticism by individuals will be introduced at sectional meetings so that the report of the committee may embody its suggestions toward remedying all obsolete or objectionable methods of procedure in the conduct of the society.

Government Offers Sodium Nitrate

The War Department has called for bids on 26,900 short tons of sodium nitrate located at the Picatinny Arsenal, Dover, N. J. The material will be sold in lots of 100 short tons or more. The bids will be opened Sept. 29 at the Philadelphia District Ordnance Salvage Board.

New Muscle Shoals Resolution Would Vest Negotiations in War Department

Representative Hull Will Press Bill to Straighten Out Tangled Interests in Big Power Development for Most Advantageous Disposal

A NEW measure for the disposition of the government properties at Muscle Shoals, which in effect would pass the entire subject back to the Secretary of War, with authority to dispose of the various units on the best terms possible, appeared in the final days of the session of Congress in the form of a resolution introduced by Representative H. E. Hull of Iowa, a member of the Military Affairs Committee.

The resolution would authorize the Secretary to sell to the Alabama Power Co. the government's interest in the Gorgas steam plant and the transmission line to Sheffield at a price not less than $3,000,000, or if unable to negotiate a sale, the Secretary would be authorized to purchase the sites and rights of way from the Alabama Power Co. at a fair price within his discretion or to take the property by condemnation proceedings if necessary.

Purchase of all property and flowage rights abutting the site of proposed dam No. 3 and which belong to the Alabama Power Co. at a price not to exceed $100,000 would be authorized, condemnation proceedings to be instituted if agreement could not be reached.

The Secretary would be authorized to complete dam No. 2 at government expense and to construct dam No. 3 and to lease these dams together with the power houses and appurtenances for not to exceed 50 years at a rental of not less than 4 per cent of the cost of finishing dam No. 2 and constructing dam No. 3, including in the latter case the cost of the site and flowage rights. The lessee would assume the obligation of keeping the property in repair during the life of the lease.

May Lease Nitrate Plants

As to the nitrate plants, the resolution provides that the Secretary in his discretion may lease for not exceeding 50 years Nitrate Plants Nos. 1 and 2 and Waco quarry, either separately or completely, at $1 per year for each plant. The condition of such lease would be that the nitrate plant or plants should be operated at capacity for the production of fertilizer components for sale to the public at a price not to exceed 8 per cent profit and that the plants be kept in condition to produce to present capacity nitrates and other components of munitions, the plants together with their personnel to be turned over to the federal government in the case of a national emergency.

The Secretary would be authorized to lease the dams and nitrate plants and quarry separately or completely to the same lessee and to make the consideration interdependent.

Authority to sell or dispose of all lands and properties owned by the government not necessary for the operation of the nitrate plants, the steam electric plants or for the construction and operation of the dams will be given the Secretary.

Ultimate Disposal Open

In explaining his resolution, Representative Hull said that it was designed to solve the problems confronting the government in connection with the Muscle Shoals project. Its terms, he said, would permit Henry Ford or the Alabama Power Co., or any other reliable person or organization, to make the contract. Mr. Hull pointed out that even the Committee on Military Affairs, composed of twenty-one members, had found it impossible to solve the problems and he predicted that it would be still more difficult for the whole membership of the House to do so. Stating that while he had signed the majority report of the Military Affairs Committee, he realized that Mr. Ford might not accept the provisions of the McKenzie bill and that this measure might be materially amended during consideration. Mr. Hull declared that his resolution would afford the Detroit manufacturer or anyone else a better opportunity to operate the nitrate plants for the benefit of the people of the country than Mr. Ford's own offer. As for the Gorgas steam plant, which Henry Ford insists be included in his bid, Representative Hull declares that "in all fairness" the Alabama Power Co. is entitled to purchase this property. Mr. Hull also believes that a 50-year lease will meet greater approval from the people than the 100-year lease in the Ford bill.

Representative Hull states that he will press his resolution at the December session of Congress.

Bureau of Mines Concludes Clay Products Study

With the conclusion of comprehensive tests and observations at brick kilns at Bradford, Pa., and at Peoria, Ill., the Bureau of Mines car, Holmes, and its crew have concluded an extended series of tests throughout the country in cooperation with the manufacturers of heavy clay products. The tests at Bradford were at a kiln of the Dressler type. That test was of particular interest, since that type of furnace has been used almost exclusively in the making of expensive clay wares. It is contended, however, that this better type of kiln can be used to advantage in ordinary brick production, since it makes possible economies not practicable in the cheaper kilns.

The crew of the car now go to Columbus and Pittsburgh to complete their calculations and to prepare their report.

Paper Production Growing Rapidly in Canada

Output Is Increased by 38 Per Cent for First Half of 1922

While the United States leads in the production of newsprint paper, the Canadian mills are growing rapidly, according to an analysis just made by the paper division of the Department of Commerce. Statistics show that there was a marked increase in production during the first 6 months of 1922 as compared with the corresponding period in 1921.

Gaining on U. S.

Canada, during the period Jan. 1 to June 30, 1921, produced 373,988 tons, as against 615,448 tons produced in the United States. In the corresponding period for 1922 Canada produced 516,506 tons, as against 690,142 tons produced in the United States. This shows an increase of 38 per cent in Canadian production, as against 12 per cent in American production. Canadian shipments for same period increased 43 per cent over the corresponding period in 1921, while shipments from American mills increased only 13 per cent.

With these figures before us there can be no doubt about the growing competition from Canada. In the United States very little has been done in the way of additional equipment for the manufacture of newsprint, whereas in Canada a number of the large mills have greatly increased their productive capacity and with one of the largest American producers opening a mill in Canada it would seem that eventually this large industry will be transferred to Canada.

Question of Wood Supply

If this industry is to be kept alive in the United States, says the report, the main problem confronting us is the supply of pulp wood. It would perhaps be impossible for anyone to make a definite statement as to our total resources, but we do know for a certainty that the supply in our Eastern and Lake States is inadequate. Thirty per cent of the newsprint manufacturing industry is in New England, approximately 50 per cent in New York and 15 per cent in the Lake State regions, and in this district as a whole the annual cut of pulp wood greatly exceeds the forest growth. In other words, in this district we have mills without forests, whereas in the Western states and Alaska we have the forests with a practically unlimited supply, without adequate production facilities. Cost of transportation prohibits bringing Western pulp wood to Eastern mills.

Ceramic Study at Cornell

A series of tests of Florida clays is now being made at Cornell University, with a view to ascertaining the value of the local production for different branches of ceramic manufacture. As a result of the work, it is expected that the brick and clay products industries of the state will be expanded materially.

Big Guns to Entertain Visitors

Many Technical Men Expected at Aberdeen During Ordnance Tests

More than one thousand engineers are expected to attend the fourth annual meeting of the Army Ordnance Association, which will be held at the Aberdeen Proving Ground on Oct. 6. A program of test firings and demonstration of the more recent developments in ordnance material and ammunition has been arranged. A year ago a similar demonstration was attended by 800 engineers. So much of value to the members of a number of classes of engineering developed on that occasion that it is believed a much larger gathering will be had at this year's demonstration.

While the invitation is limited to members of the Army Ordnance Association, the American Society of Mechanical Engineers and the Society of Automotive Engineers, it is pointed out that there will be so many features on the program of interest to chemists, electrical and civil engineers that a large representation from these branches of engineering probably will be present. The requirements for an invitation can be met by anyone who is not a member of any one of the three societies mentioned by taking out membership in the Army Ordnance Association. Any American citizen is eligible to membership in that organization who is interested in extending and disseminating technical knowledge which has a bearing on the improvement of munition power as a factor in maintaining peace. Such a person can be enrolled as a member of the Army Ordnance Association on remitting $5 to cover the annual dues.

Tests of Flashless Powder

Chemists will be interested particularly in the tests of the recently devised non-hygroscopic, flashless, smokeless powder. The tendency of smokeless powder to absorb moisture has interfered with its ballastic properties. Efforts long have been under way looking to the control of the combustible gases which ignite on contact with the air and result in the flash which it is so desirable to eliminate in the use of artillery.

At the Railway and Seacoast Range a 16-in. gun en barbette and a 16-in. howitzer at high angle using solenoid chronograph will be demonstrated. Armor-piercing projectiles of various calibers which have passed through armor plate and the penetrated armor plate will be exhibited. Two 600-lb. bombs will be dropped from an airplane in the water, one with delay action fuse and one with instantaneous fuse.

Upon conclusion of the exhibition at the Railway and Seacoast Mount Range, the party will remain aboard the train and proceed to the aviation field. Upon arrival there, the party will detrain and inspect an exhibition of bombs, at which all types of American bombs and all available types of foreign bombs will be shown. The party will then witness a demonstration of machine gun firing from airplanes. This demonstration will be made on the ground in order that details may be visible. The plane is the DH4B, an observation and day bombing type. Firings will also be made with plane in air. The ammunition will be about 20 per cent tracer bullets.

The party will then inspect the airplanes and the dirigible balloons which are on hand at the proving ground. Flights will be made after inspection.

Luncheon will be served at the Visitors' House at 12:45 p.m. Immediately after luncheon the party will entrain and proceed to the main front, at which place it will detrain in order to witness the exhibition of various ordnance material.

At the main front a number of rounds will be fired from mobile artillery material for comparison. Firings will also be conducted from six powder guns or machine guns mounted in a moving tank, the target being an old tank on the main range.

Small Arms and Machine Gun Material

There will be a small arms booth at which will be shown the latest types of small arms and machine guns and their ammunition. Machine guns of various calibers will be fired with ordinary ammunition, armor-piercing ammunition and bursts of tracer ammunition. Firings of the 0.30-caliber and 11-mm. will be made against toy balloons and the 0.50-caliber against a tank or tank armor target.

At this time there will be dropped from planes one 2,000-lb. bomb for function test from an altitude of 8,000 ft., two 600-lb. bombs equipped with Mark V and VII nose and tail fuses. One fuse will be set for instantaneous function, the other for delay action.

As soon as the firings as outlined above have been completed a variety of self-propelled mounts, tanks, tractors and trailers will be exhibited and maneuvered.

Upon completion of the demonstration at the main front, the party will be conducted to the Exhibition Building for the purpose of inspecting the various automotive vehicles and other equipment in the building. Dinner will be served at 5:45 p.m., after which firings will take place from the main front, which visitors may witness if they so desire. A train will leave the Visitors' House for the main front for this purpose at 6:50 p.m. These firings will include demonstration of flashless powder, 75-mm. gun or other caliber; 0.30-caliber tracer ammunition; 11-mm. tracer ammunition; 0.50-caliber tracer ammunition; pyrotechnics.

Immediately after this firing, at about 7:30 p.m., the Proving Ground train will leave the main front, stopping at the Visitors' House for the purpose of taking the party to Aberdeen to catch the trains going north and south.

Action of Alkali on Concrete to Be Studied

Canadian Interests Co-operate in Investigations of Effect of Soil

The governments of the Dominion, Alberta and Saskatchewan, the Canadian Pacific Railway and the Canada Cement Co. have provided funds and have appointed a committee of experts under the chairmanship of Prof. C. J. Mackenzie, of the University of Saskatchewan to make an investigation of the action of alkali soils and waters on concrete. In a number of instances in the prairie provinces the action of alkaline salts in the soil has so deteriorated concrete foundations that alarm is felt for the safety of structures superimposed on them.

The word "alkali" as applied to soils and waters is used exceedingly loosely in the west, being made to cover practically any salt of the alkalis or alkaline earths, or any group of such salts, quite regardless of whether they are acid, alkaline or neutral. The nature of so-called alkali waters varies enormously in different parts of the Canadian West. Lakes are found within a comparatively short distance of each other in which the predominating salts are sodium sulphate, sodium carbonate and magnesium sulphate, respectively; and these salts occur in sufficient quantity to make the commercial recovery of them a profitable enterprise during the drier months of the year, when the concentration is greatest. In the northern part of the prairie provinces springs, the waters of which are saturated with sodium chloride and with sodium and magnesium chlorides, are common, so it will be evident that the investigators have a broad problem before them, for, obviously, a remedy that might combat one form of "alkali" may be ineffective against another.

A fund has been created to finance the work totaling $13,200, of which the Research Council of Canada gave $5,000.

Chemical and Physical Tests

It was decided to divide the work into two phases: physical field tests and chemical research. Two hundred and fifty blocks of cement were exposed to the action of alkaline water at different points, this stage of the experiments being conducted under the charge of Professor Williams of the University of Saskatchewan. The work is now about to enter on the second stage, that of chemical research. The test blocks will be taken to the University of Saskatchewan and there chemical research work will be carried on under Professor Thoroldson, assisted by five chemists. It is not expected, however, that any results will be ready for publication for another year.

Disintegration of cement construction, under the influence of alkaline water, has, it is stated, reached such a point that until more is known, it is doubted whether cement can be used where alkaline water is encountered.

Hearings Open on Bill Providing Hydraulic Lab

Advocates Claim That Establishment Would Pay Dividends

In the course of the hearing on the bill providing for a National Hydraulic Laboratory, Senator du Pont of Delaware pointed out that industries are doubling and trebling their laboratory expense. John R. Freeman, the president of the American Institute of Civil Engineers, in advocating a laboratory to study flood control and all the problems of river hydraulics, declared that in his experience of more than 40 years he had never known a laboratory of any character which had not paid dividends, in some cases as high as thousands per cent.

Secretaries of the three executive departments that will be affected by this legislation were asked to submit reports and opinions on its establishment. The Secretary of Commerce and Secretary of the Interior see in the laboratory an important aid in solving problems of river hydraulics, while the Secretary of War submitted an adverse report, which is believed to reflect the opinion of the Corps of Engineers.

Secretary Hoover has submitted the following opinion: "There are many problems arising in connection with hydraulics, irrigation and the determination of the fundamental laws relating to stream flow and deposit which such a laboratory would assist in solving. Without question, the solution of the tremendous waste problem due to floods rests on fundamental data concerning the flow of water, the wearing of structural and natural materials, the transportation of material and water, and chemical and physical deposition, together with such general field data as can be gathered all over the country."

Secretary Fall states: "This department for many years has recognized the necessity and the value of scientific research in river hydraulics undertaken to obtain accurate and reliable data for use in the design, construction and operation of works intended for the utilization and control of the rivers of the country."

Weeks Opposed

In contrast to these opinions, the Secretary of War states that: "The hydraulic laboratory proposed would have no value whatever in solving flood control." He further states that he "would regard it as a misapplication of government funds to establish such a laboratory for the study of flood problems."

Further extracts from his letter are as follows: "The measures that can be taken to control floods are limited to the construction of dams to hold back the waters, levees to prevent them from overflowing the land, and such enlargements and outlets as may be practicable to pass the flood as promptly as possible to the sea. I omit reforestation, which some claim would have a beneficial effect, as, in my opinion, any effect of reforestation on the flood problems of this country is too insignificant to warrant serious consideration.

"It has been established that the reservoir control of the Mississippi flood problem is not practicable. In any event, the art of dam construction is so far advanced in this country that a national hydraulic laboratory is not necessary to advance that science. The hydraulic laboratory is certainly unnecessary to determine the proper design of the levees.

"There remains the problem of the practicability of designing outlets on the basis of laboratory experiments. I think it should be clear that the forces of nature let loose in a flood in one of our great rivers cannot be reproduced in a laboratory."

Ohio State Chemists at Pittsburgh A.C.S. Meeting

The accompanying photograph, taken on the steps of Carnegie Music Hall during the Pittsburgh meeting of the American Chemical Society, shows the large representation of chemists from Ohio State University that attended the meeting. The picture was taken immediately after the Ohio State luncheon on Sept. 6 at which ninety were present. Many meetings of various institutions were held during the convention, but this was the largest luncheon or dinner attendance reported by a single university.

Birds' Happy Home Doomed by Oil Seekers

Charles Stewart, Dominion Government Minister of Interior, has announced that his department has made an arrangement with a powerful United States syndicate by which the famous Pakowski bird sanctuary is to be thoroughly explored for oil. The bird sanctuary, which is 44 square miles in extent, lies immediately to the north of the Sweetgrass oil field in Montana and according to Dr. Dowling, oil expert for the Canadian Geological Survey, the oil-bearing formation extends well into southern Alberta.

Under the terms of the arrangement, the syndicate has been granted three leases of 640 acres each, and in the event of discovery is to be granted one-half of the whole sanctuary, in consideration for which it is to explore thoroughly the leases it has been granted. Mr. Stewart points out that the Dominion Government will retain the other half of the sanctuary, which, in the event of the discovery of oil in commercial quantities, will be greatly enhanced in value. Mr. Stewart stated that he recently visited the Montana field, where forty drilling outfits are at work. Work already has been started on the Canadian side, and Dr. Dowling is on the ground, watching developments on behalf of the Dominion Government.

American Sulphur Industry Competing Successfully With Italian

A message from Palermo, Italy, says that owing to the development of the sulphur industry in America and the fall in freight rates, American producers are competing very keenly on the sulphur market and the situation of Italian producers is becoming daily more difficult. The consortium holds stocks which cannot be disposed of except at serious losses. The following figures show the decrease in the export of Sicilian sulphur and the increase in the American production:

	Metric Tons	
	1920	1913
Italian exports.....	148,044	351,338
American production	1,230,000	498,937

Short Course for Flour Chemists an Innovation in Education

Unique in being the only educational project of its kind in the world, a 4-day short course for flour mill and bakery chemists has been scheduled at the University of Minnesota for Jan. 2 to 5, 1923. Complete and intensive instruction in the latest developments in the chemistry of flour and baking will be given by university experts of the agricultural biochemistry division. Supplementary lectures on wheat classification, wheat breeding, wheat diseases and insects infesting wheat and flour are also planned. Attendance will be restricted to twenty-four, and registration opens Oct. 1, 1922.

Canadian Paper Makers Oppose Development of Newfoundland

British manufacturers of print and other pulp papers have joined with Canadian manufacturers in opposing British aid to the proposed pulp and paper industry development of Newfoundland and admit in their protest to the British Government that their opposition is based on the fact that manufacturing costs in Newfoundland will be so small that the closing of British mills will result.

This information was contained in a cablegram received from Sir Richard A. Squires, Premier of Newfoundland, who has been in London several weeks negotiating with the Imperial Government for aid under the British trade facilities act. The proposed development in Newfoundland includes the harnessing of the Humber River. The cablegram received from Premier Squires follows:

"Canadian pulp and paper interests have succeeded in getting the Paper Makers Association of Great Britain and Ireland to enter formal protest to the Imperial Government against any guarantee being granted under the trade facilities act for the development of water power and timber areas in Newfoundland, on the ground that timber areas in Newfoundland are so vast and water power so gigantic that the manufacture of pulp and paper in Newfoundland on a large scale would have the effect of closing the paper mills in Great Britain because Great Britain paper manufacturers could not compete with Newfoundland manufacturers in quality or price."

Trade Association Will Foster Russian Paper Industry

That the immense possibilities of Russia as a source of wood pulp and paper are not being overlooked by the Soviet Government is indicated by the organization of a so-called Tecnic-Economical Council of the paper industry which has recently been formed, with headquarters in Moscow. The report of the formation of this organization sets forth as its object the correlation and dissemination of scientific, technical and economic information for the benefit of the industry and the education of the public. The council plans to maintain a library, an experimental laboratory and a vocational training school, and plans to enter into relations with the scientific and technical associations of Europe and America.

The council has three sections—the technical, the economic, and the professional instruction sections. General meetings are to be held every 2 months. The board of directors consists of five persons. Work of the council is financed by the manufacturing concerns which make up its membership.

Reports are current of the formation of an American company for the operation of a pulp and paper mill in Russia, which has been approved by the Soviet. The names of the Americans who are promoting the enterprise have not been made public, and particulars of the plant and its location are not at present available.

E. C. Franklin Plans Lecture Tour

At the Pittsburgh meeting of the chairmen and secretaries of the various divisions of the American Chemical Society, a plan was launched by which Prof. E. C. Franklin of Leland Stanford University will give a series of lectures before several of the local sections of the society. These will be given near the time of the spring meeting—that is, the latter part of March and the early part of April. The following sections have asked Dr. Franklin to speak before them on this trip: Chicago, Detroit, East Lansing, University of Michigan, Purdue, Cleveland, New Orleans, West Virginia, Pittsburgh, Buffalo, Rochester, Syracuse and Philadelphia.

If there are other sections of the American Chemical Society or other scientific bodies which would like to have Dr. Franklin speak before them, information can be obtained by writing to E. M. Billings, Kodak Park, Rochester, N. Y.

Free Courses in Dyeing at New York Textile School

Registration is now open at the New York Evening Textile High School, 124 West 30th St., New York City, for two courses in dyeing which will enable those interested to obtain a wider perspective of the entire field of the textile and dyeing industries.

The first of these courses, the elementary, is given on Monday and Wednesday evenings, and the advanced course on Tuesdays and Thursdays. The class is held from 7 to 9 p.m. and the work is partly lecture and partly laboratory, the former consisting of talks on textile fibers and dyes, while the latter covers practical dyeing. From time to time lectures will be given by authorities in the profession. All instruction and materials are free.

Capital Increases Rumored for German Dye Concerns

A Berlin dispatch to the New York *Times*, dated Sept. 24, states that new stocks in the German dye industry to the extent of 1,800,000,000 marks are expected to be thrown on the market in the near future. As a forerunner of this the directorates of two large firms already have decided to virtually double their capital stock.

The firm of Farbwerke, formerly known as Meister Lucius & Bruening of Hoechst-on-Main, has voted an increase of 470,000,000 marks, which will make a total capital stock of 940,000,000 marks. Other concerns in this group have similar increases in prospect. The directorate of the Chemische Fabriken has decided to increase its total stock from 33,000,000 to 64,000,000 marks.

Regulation of Butter Substitute in Canada

Under the regulations effective Au 19, importation, manufacture and sa of margarine in Canada shall be special license only, and the manufa ture of nut butters and oleomargarin is prohibited wherever the manufactu of butter or the reworking of ranc butter takes place, Vice-Consul Vys Ottawa, informs the Foodstuffs Div sion of the Department of Commerc Even the materials used for the man facture of dairy butter substitute mu undergo official government inspectio and approval, so interested are th dairies in safeguarding the health o the people preferring nut butters. I a picture of a cow or the name of an breed of cattle or the words "butter, "creamery" or "dairy" appear upon th package of dairy butter substitute o are used in advertising the article, th manufacturers are heavily liable.

Among the many sale restriction there is one that margarine must b sold in the original package, must b stamped with the official inspection sea of the Canadian Dominion, Ministry of Agriculture, and must conspicuously bear the word "oleomargarine." If a restaurant, hotel or lunch room serves margarine and doesn't announce that fact by prominent notices around the walls of the dining rooms, in the kitchens and elsewhere, it is a violation of the law and will cost about $500.

Chemical Industries Growing in India

The Bengal Agricultural and Industrial Committee has recommended the expansion of the manufacture of sulphuric acid and the establishment of factories for the manufacture of white lead, red lead, etc. Raw materials are readily obtainable.

The question of the manufacture of cement in the Jaffma island is being investigated. The experiments in testing materials carried out by the Technological Institute at Cawnpore have proved the feasibility of starting cement factories at Cawnpore and Lucknow.

The Director of Industries, Mysore, has been asked by the Durbar to ascertain if any private capitalist is willing to establish a paper factory in the state under the scheme prepared with the assistance of Bertram & Sons, of Edinburgh.

It is understood that the Nizam's Government has granted concessions to the Oosmania Mills Co., Ltd., which has been registered with a capital of one crore to start four cotton mills in the Hyderabad State.

Civil Service Openings

The U. S. Civil Service Commission announces the following open competitive examinations: Laboratory assistant, senior grade, at $1,200 to $1,380 a year; laboratory assistant, junior grade, at $1,000 a year; senior aid, at $900 a year; junior aid, at $540 a year, and junior aid, grade 2, at $720 to $840 a year.

Dye Embargo Dies Hard

(Continued from page 658)

Secretary; that imports be confined to certain specified ports; and that the tariff bill be amended so as to provide that the decision of the Secretary as to similitude be final and without appeal. Subsequent to the receipt of this letter the tariff conferees extended the embargo in the bill and placed the rates on coal-tar products on foreign valuation. They, therefore, did not make any changes in the text suggested by the Secretary. The House rejected the embargo and recommitted the bill to conference to have it stricken out. In their second conference, which lasted only 4 hours, the conferees changed the basis of the valuation on coal-tar products back to the American selling price and changed the figures in the paragraph, but found themselves unable to make the changes in phraseology which had been suggested by Secretary Mellon.

The greatest difficulty expected in administering the tariff on coal-tar products as it appears in the bill now is in determining similitude. The paragraph reads that imported dyes and chemicals from a coal-tar base shall be assessed for duty on the basis of the selling price of a comparable American product and that a domestic product may be considered comparable with an imported product if it produces results "substantially equal." The determination of whether results are similar is expected to lead to considerable litigation. In a case where similitude is not claimed and where there is no directly comparable American product, the rates are to be assessed on the foreign selling price or the export price, whichever is the higher.

Plan to Ask Readjustment of Rates

The movement for rearrangement of the duties not only on coal-tar products but upon synthetic organic chemicals of non-coal-tar origin was begun before the death of the temporary embargo extension. In a letter to all Republican members of Congress, dated Tuesday, Sept. 19, Dr. Charles H. Herty, president of the Synthetic Organic Chemical Manufacturers' Association, asked that the embargo be extended for 3 months and in concluding his letter said: "The enactment of this resolution will protect our industry and give time for the framing of legislation based on rates, which will safeguard the uncompleted American industry."

The exact basis of rates which will be asked when Congress reconvenes has not been determined, but in general it is proposed to increase greatly the 25 per cent ad valorem foreign valuation duty on synthetic organic chemicals (under the general or "basket" clause) and to rearrange completely the rates on coal-tar products. It is proposed in the case of the latter to make more than one rate, as it is claimed that some of the products need very high protection, while others can exist on low protection. The rates in the new tariff act on coal-tar products are 55 per cent ad valorem, American valuation, plus 7 cents per pound on intermediates, and 60 per cent ad valorem, American valuation, plus 7 cents per pound on finished products, these rates to continue 2 years, after which the ad valorems are to be reduced to 40 and 45 per cent, respectively.

Wisconsin Gives First Course in Paper Making by Mail

The first correspondence study course on the manufacture of pulp and paper will be given this September by the University of Wisconsin extension division in co-operation with the Forest Products Laboratory. The vocational education committee of the pulp and paper industry and the Wisconsin Board of Vocational Education helped to plan the course.

Five courses based on the textbooks prepared by the vocational education committee of the pulp and paper industry will be given. According to the co-operative arrangement, the extension division will administer the courses and the Forest Products Laboratory will correct the papers and have actual charge of the teaching of the courses. All of the information in the laboratory files and such technical advice as the members of the pulp and paper staff can give will be available to all students who take the course.

Railroad Must Stand Cost of Spotting Freight Cars

The Indiana Harbor Belt R.R. Co. has been ordered to pay the United Chemical and Organic Products Co. and the Central Chemical Co. of West Hammond, Ill., the costs of terminal service performed by the chemical companies' engine. The spotting of cars and other work in handling shipments from their own establishments was undertaken by the chemical companies when the belt railroad was not in a position to furnish prompt and adequate terminal service.

Paper Mill for East Kootenay, B. C.

The Wigwam Pulp & Paper Co., Ltd., has been formed for the purpose of building a pulp and paper mill at Philip's Bridge, 9 miles from Elko, in the East Kootenay region of British Columbia. The company is composed of United States and Canadian capitalists, the Chicago *Tribune* and other large daily paper owners being interested. The plant is to be built in three units, each having a daily capacity of 100 tons of newsprint, and a contract for the construction of the first unit, which is to cost $3,500,000, has been let to McDougald-McNeil, Ltd., of Calgary.

It is stated that it will take 3 years to build the complete plant, which will cost in the neighborhood of $12,000,000 and when finished will give employment to 1,500 men. Timber limits assuring a supply of pulpwood over 30 years are said to have been obtained, also water rights on the Elk and Bull rivers, providing ample power.

Natural Tannic Acid Plant to Be Established in Fiji Isle

Melbourne, Australia, papers report that the Doga Timber & Tannin Extraction Company has been formed in Suva, Fiji, for the purpose of extracting tannic acid from the bark of the doga tree, which grows in the mangrove swamps on the foreshores all around the islands. The proposal is to extract the tannic acid and ship the crystals to England. The company has a monopoly of Vitilevu, the largest island. Machinery has been imported, and operations are to be started soon.

Personal

EDWARD BARTOW and his family returned to the United States Sept. 2 after a 3 months' trip in Europe.

A. B. DAVIS and R. W. HILTON, formerly with the firm of Ault & Wiborg, have formed the firm of Hilton & Davis, to be manufacturers and distributors of fine chemicals.

FEDERICO GIOLITTI is at present in the United States.

HARRY H. HILL, formerly superintendent of the Bartlesville experiment station of the Bureau of Mines, has been designated to succeed F. B. Tough as supervisor of oil and gas leases. He will be succeeded by Theodore E. Swigart.

H. W. LOEBEL of McGill University, Montreal, Canada, has recently been added to the staff of the National Malleable Castings Co., Chicago, Ill.

RUSSELL E. LOWE, formerly works manager and technologist for the Maine Power Sales Co., maker of ferroalloys, is now metallurgist in charge of operation for the Bario Metal Corporation of New York.

R. B. MOORE, chief mineral technologist of the Bureau of Mines, is making a tour of the bureau's experiment stations in the West.

HENRY C. PEARSON, editor of the *India Rubber World*, will celebrate on Oct. 1 the thirty-third anniversary of the publication of which he has been editor from the beginning. Not only are there few business publications today that have reached the advanced age of 33, but there are still fewer editors who enjoy the unique distinction of having directed the editorial policies of their magazines from the beginning. *Chem. & Met.* extends its congratulations and best wishes.

J. A. STEFFENS, for the past 5 years chemical engineer of the U. S. Industrial Alcohol Co. at the research laboratories in South Baltimore, Md., has resigned and will engage in business for himself in New York.

WILLIAM STERICKER, formerly an industrial fellow at the Mellon Institute, Pittsburgh, Pa., is now research chemist with the Philadelphia Quartz Co., Philadelphia, Pa., the donor of the fellowship Mr. Stericker held at the Mellon Institute.

Market Conditions

In Chemical, Metallurgical and Allied Industries

Prevailing Prices and Market Letters From Principal Industrial Centers

The Tariff Act of 1922 and Its Probable Effect on the Chemical Market

A Study of the Rates of Duty and Administrative Provisions Most Likely to Influence Trade in the Products of the Chemical Industry

DOUBTLESS the single factor most likely to have permanent effect on market conditions in the chemical and allied industries is the new tariff law, signed by the President on Sept. 21, 1922. A certain measure of relief is to be felt immediately simply because the final enactment of the Fordney-McCumber bill puts an end to the 20 months of uncertainty which have characterized its making. To be sure, there is a wide difference of opinion as to probable revenue yields, the effects on domestic prices and on foreign trade, but aside from these controversial issues there are certain provisions in the new law which are of vital and immediate interest to the chemical industry.

The Possibilities in the Flexible Tariff

The outstanding feature of the new law is the provision empowering the President to raise or lower duties following the recommendation of the Tariff Commission. Under this arrangement rates of duty can be altered within the range of 50 per cent in order to meet changing conditions of competition or to correct inequalities in the operation of the different provisions.

Tariff Chronology

Jan. 6, 1921. Hearings began by Ways and Means Committee.
June 29, 1921. Bill introduced into the House of Representatives.
July 21, 1921. Passed by House.
July 22, 1921. Referred to Senate Finance Committee.
July 25, 1921. Hearings begun by Finance Committee.
Jan. 3, 1922. Hearings concluded.
April 11, 1922. Reported to Senate.
Aug. 19, 1922. Passed by Senate.
Aug. 22, 1922. Referred to conference.
Sept. 11, 1922. Reported by conference.
Sept. 13, 1922. Returned to conference by House.
Sept. 15, 1922. Conference report approved by House.
Sept. 19, 1922. Conference report approved by Senate.
Sept. 21, 1922. Fordney-McCumber tariff signed by the President.

The surrender to this extent of the Congressional prerogative of rate making is the first step toward taking the tariff out of politics and placing it on a logical and scientific basis. This provision offers many difficulties in the way of administration, but the success or failure of the new law will depend largely on the way in which the flexible tariff clauses are interpreted by the executive and administrative agencies.

As in all previous tariff acts, the ad valorem rates are based on foreign valuation with the single exception of coal-tar products, where the American selling price is the basis of assessment. It will be recalled that the House originally applied American valuation to the entire act, but because of very strong protest the provision was eliminated by the Senate. It is significant, however, that under the flexible tariff clause the President may extend American valuation to other articles where the additional protection is deemed necessary.

Dyes and Coal-Tar Products

The chemical industries are most concerned with the rates imposed on their products. In the accompanying table these rates have been compared

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	146.86
Last week	146.67
September, 1921	147
September, 1920	267
April, 1918 (high)	286
April, 1921 (low)	140

Indications are that the chemical market has already reached the lowest level of its present movement and unless interrupted by difficulties now unforeseen, it may be expected to show a gradual but material improvement within the next few months.

A COMPARISON OF THE RATES OF DUTY ON IMPORTANT CHEMICALS IN THE FORDNEY-McCUMBER TARIFF ACT OF 1922 AND IN ITS PREDECESSOR, THE UNDERWOOD-SIMMONS ACT OF 1913

(Specific Duties are on per pound basis unless otherwise noted.)

* Not specially provided for.

† Depending on strength o grade.

‡ After 2 years the ad-valorem rates on intermediates and dyes will be reduced respectively to 40 and 45 per cent. These duties are to be based on the American selling price of similar competitive articles of American manufacture. Lacking such an article the duty is based on the American selling price of the imported article.

§ Provided the country of origin assesses no duty on calcium acetate when imported from the United States.

with those in the Underwood-Simmons ct of Oct. 3, 1913.

Of most general interest are the rates n dyes and other coal-tar products. The Ways and Means Committee, the Senate Finance Committee and the oint conference each had the experi-nce of inserting provisions for the ex-ension of the recent embargo system—nd each in turn saw it rejected. After he House had returned the bill to the onferees with instructions that they liminate the dye embargo and place otash on the free list, it was evident hat a higher tariff was the only accept-ble compromise. Accordingly in the ew law the coal-tar products known s intermediates and used in the manu-facture of such finished articles as lyes, medicinals and photographic hemicals are made dutiable at 1c. per b. and 55 per cent ad valorem based n the American selling price of any imilar competitive product made in the Jnited States. These rates, however, re to apply for only 2 years, after vhich time they are to be reduced to 0 per cent ad valorem and 7c. per lb. The finished coal-tar products—dyes, stains, color lakes, medicinals, aromatic chemicals, flavors, synthetic tanning materials, synthetic resins and explosives—are to be dutiable at 60 per cent ad valorem and 7c. per lb. for 2 years and thereafter the ad valorem rate is reduced to 55 per cent.

If there is no "similar competitive article" manufactured in the United States, then the ad valorem rate is to be based on the foreign value of the product plus certain specified additions for packing, shipping, etc. The terms "similar" and "competitive" are defined as follows:

> Any coal-tar product provided for in this act shall be considered similar to or competitive with any imported coal-tar product which accomplishes results substantially equal to those accomplished by the domestic product when used in substantially the same manner.

Many Synthetic Organic Chemicals Are Unprotected

Except for those of coal-tar origin and a few others mentioned specifically in the different paragraphs, synthetic organic chemicals are not specifically provided for and must therefore be included in the basket clause of paragraph 5 at a rate of 25 per cent ad valorem. This is a tremendous reduction in duty, for under the Bursum amendment to the Senate bill all synthetic organic chemicals, whether of coal-tar origin or not, were to receive the high compound duties based on American valuation. The compounds which suffer most by this omission are the organic medicinals such as barbital, certain of the acetylene, ethylene, propylene and other hydrocarbon derivatives, and many of the highly purified chemicals developed for research and experimental purposes.

Dye Duties Based on Strength

There are two important administrative features of the dye schedules which have appeared in all of the varied drafts of the bill but which have not received the attention they deserve. The first provides that the specific duties on dyes shall be based on standards of strength to be established by the Secretary of the Treasury and on all im-

portations which exceed these standards the duty shall be computed on the weight the article would have if it were diluted to standard strength. This will make it necessary for the Treasury Department to sample and report on all dye imports, but it will have the beneficial effect of preventing evasion of duties through the importation of highly concentrated dyes and their subsequent dilution in this country. Incidentally the standards of strength are to conform as nearly as practicable with those in ordinary commercial usage in this country prior to July 1, 1914.

The second provision is that beginning March 21, 1923, every package of imported dyes must be labeled with a "plain, conspicuous and truly descriptive statement" of the identity and percentage of actual dye contained therein. Furthermore, this label must not bear any fraudulent or misleading statement regarding the origin of the dye. This application of the principles of the pure food and drugs act to dyestuffs is an innovation that should eventually result in a marked improvement in the marketing of both imported and foreign dyes.

Other Changes in the Chemical Schedules

Potash as a result of the final mêlée in the conference was relegated to the free list—that is, as far as the crude salts are concerned. The refined compounds of potassium, with the exception of KCN, carry specific duties ranging between one-half cent on the nitrate and 25c. per lb. on the iodide.

Ammonium sulphate, originally introduced in the House bill with a duty of two-fifths of a cent per lb., emerged from the conference with the ¼c. rate imposed by the Senate.

Citric acid, always a source of controversy in tariff debates, was finally made dutiable at 17c. per lb. after the duty on its raw material, citrate of lime, had been boosted to 7c. per lb.

The rates on the higher strengths of lactic acid were increased to 4c. per lb. for the 30-55 per cent grades and 9c. per lb. for all strengths above 55 per cent.

The Underwood rate on fusel oil was ½c. per lb. The House bill raised this to 6c., which was subsequently lowered to 2c. by the Senate, but the conferees saw fit to return to the House rate of 6c. per lb.

Casein had been on the free list for many years when the emergency tariff separated it out for a protective duty. In the new law it continues to be dutiable at a rate of 2½c. per lb. The plastic compounds of casein known as galalith are mentioned for the first time in this tariff act.

A feature of the vegetable oil paragraph is that all of the rates, with the single exception of rapeseed oil, are based on weight rather than measure. In the case of many of the oils which are imported in large quantities it has always been a difficult matter for the customs officials to assess duties based on gallonage when the products are bought and sold on a pound or ton basis.

I.C.C. Modifies Rail Priorities

In a service order effective Sept. 20, the Interstate Commerce Commission has modified its rules regarding preferential shipments eastward from the Mississippi River. Medicines, fertilizers, seeds, newsprint paper, mine supplies and petroleum have been added to the list of commodities entitled to priority movement.

It is understood that the new order was issued because of the complaint that various commodities had not been handled currently and promptly because of the different embargoes issued by the railroads during the coal and rail strikes.

The New York Market

New York, Sept. 24, 1922.

The enactment of the new tariff bill has already had some influence on the prices of chemicals and allied products. Advances have been quite common, especially among items frequently imported. The market, in general, may be said to be decidedly stronger than at any other time this year, and while business has not been materially increased, the consuming element has shown some inclination to emerge from its former status of extreme conservatism. The feature of the past week's activities has been the advance in acetate of lime quotations. This has been the third increase during the past few months and it is understood that prices on all acetate products will automatically be higher. Crude fusel oil and tartaric acid manufacturers have advanced quotations. Acetate of soda, sal ammoniac, barium chloride and carbonate, caustic potash, permanganate of potash, prussiates of potash and soda have all shown more activity at higher figures during the interval. Imported citric acid is soaring under the impetus of the 17c. per lb. duty provided by the new tariff.

General and Special Chemicals

Acetate of Lime—Increased production costs have been directly responsible for the recent advance in this commodity. Supplies are very firm among producers at $2.75 per 100 lb. Demand is fairly active.

Acetate of Soda—Spot and immediate shipment material is in very light supply and sellers have advanced quotations to 7½c. per lb. Buyers are showing considerable interest in the position of available supplies.

Barium Chloride—Large dealers were quite firm around $97 per ton for spot supplies. The general tone of the market is much firmer and the consuming demand has been moderately active.

Caustic Potash—The demand for this item has shown an appreciable increase and prices have been materially advanced. During the late trading 6½c. per lb. for 88-92 per cent goods was considered an inside figure for spot material.

Chlorate of Potash—Domestic factors were quoting 8½c. per lb. f.o.b. works.

Citric Acid—Imported material has been advanced to 48½c. per lb. on spot. Domestic producers are withholding quotations in an effort to prevent second-hand speculation. The shipment market is a nominal affair.

Nitrite of Soda—Prices have been firmly maintained at the recent advance and 9¼c. per lb. was about the lowest figure heard on actual transactions. Offerings were rather light on spot.

Prussiate of Potash—Yellow material was quoted as high as 37c. per lb., although on some odd lots a shade lower might have been done on firm business. The red variety held at 95c. per lb. Demand has been quite active of late.

Prussiate of Soda—Leading dealers quoted the spot market around 24@24¼c. per lb. The general tone of this market is much firmer than recently reported, due to the added costs of importations.

Sal Ammoniac—Sales of imported white granular were reported at 6½c. per lb. Some sellers were asking from 6¾@7c. per lb. The demand has shown a noticeable increase and sellers have shown no anxiety to offer any large quantities.

Tartaric Acid—Producers have advanced prices of the U.S.P. to 32c. per lb. on all varieties. Imported crystals were quoted at 31c. per lb., with the powdered at 31¼@31½c. per lb.

Coal-Tar Products

The market, in general, has been much healthier during the past week and producers are all of the opinion that the last quarter will bring considerable activity on items that have been dormant during the earlier months of this year. There has been a pronounced scarcity, with very little relief in sight, in phenol, toluene and benzene.

The selective embargo on coal-tar products contained in the emergency tariff law came to an end on Sept. 21, 1922, with the enactment of the new tariff law. It would appear quite probable that imports of certain crudes now on the free list may again appear on the market shortly.

Aniline Oil—Large factors quote the market at 15c. per lb. and report several sales at this figure. The tone of the market is somewhat stronger.

Benzoic Acid—The market remained quite firm and producers report sales at 72@75c. per lb. for the U.S.P. material. Small lots seemed to feature the trading.

Beta Naphthol—The demand for the technical variety has not been very active and the tone was much easier. Producers quote 23c. per lb. for immediate shipment.

Cresylic Acid—Prices on this commodity were very firm and sellers found some difficulty to meet the increased demand. The 97-99 per cent is quoted around 56@58c. per gal. and the 95 per cent at 51@53c. per gal.

Phenol—Producers named 18@20c. per lb. for shipments. Spot supplies are very light and holders are asking 21@22c. per lb. for the U.S.P. prime white crystals. The general condition of the market is extremely firm.

The St. Louis Market

ST. LOUIS, Sept. 19, 1922.

Trading conditions in this market ve been very good during the past weeks and prices very firm. The de- and for domestic goods is increasing adily, as stocks of imported material e comparatively light.

ALKALIS

Apparently the alkali market has ached the period of "normalcy." For ite a while now there has been no ange of note in prices, while the lume of business being done is at ast normal. *Solid caustic soda* in 5- 10-drum lots is holding firm at $3.90 r 100 lb. delivered buyer's door and *ke caustic*, on the same basis of antity and delivery, is quoted at .25. *Soda ash* is also thriving on a isk market, and while no advance in ices has been reported, volume of siness is good. In 5- to 10-bag lots is quoted at $2.20 per 100 lb., with e usual differential of 20c. for bar- ls. *Bicarbonate of soda* is moving in s usual channels and has retained the ice of $2.25 in 5-bbl. lots. Carload otations in this market are around .85 per 100 lb,. f.o.b. buyer's ship- ng point. *Sal soda* is the weak sister the alkali group at this time and is ally without a price. Prices range om $1.50@$1.75 per 100 lb. in 1- to bbl. lots.

GENERAL AND SPECIAL CHEMICALS

Heavy mineral acids continue to ove in a fair way with prices un- anged. With the government surplus ocks of *carbolic acid* practically de- leted, the market is becoming very rm and the demand seemingly good. *itric acid* is not moving so well. *mmonia water*, 26 deg., is moving rough regular channels and prices re- ain the same. *White arsenic, pow- ered*, is still in heavy demand and sup- lies are light, with prices ruling about ie same as our last report. There as been very little change in the *rpperas* situation and the market is ery firm. *Glycerine* has enjoyed an- her advance since our last report and now quoted on a firm basis at 17½c. er lb. in drums. We expect to see our revious prediction of 18c. glycerine ulfilled in the near future. *Sulphur* as not changed since our last report nd has, we think, reached bottom. While there has been no startling mount of sulphur business transacted ecently, the market can scarcely be alled stagnant.

VEGETABLE OILS AND NAVAL STORES

Castor oil is still holding firm at 4c., with no indication of a decline. would not be at all surprising to see further advance soon. *Turpentine* as advanced sharply again and to- ay's quotation on single barrels is 1.40 per gal. and 5-bbl. lots at $1.34. *inseed oil* has generally remained teady at the market price, with no hanges and good volume of business ransacted.

The Iron and Steel Market

PITTSBURGH, PA., Sept. 22, 1922.

Production of steel is now at between 60 and 65 per cent of capacity. The gain in the past week has been small relative to the gain which rather promptly followed settlement of the coal strike. Quickly a movement was re-established between mines owned by steel interests and their byproduct coke ovens and steel plants. Further increase would depend chiefly upon increased supplies of purchased coal or of coal or coke from the Connellsville region. The last weekly report of the Geological Survey expressed the opinion that the limit of coal production has been practically reached, having got up to the present transportation capacity of the railroads. Until conditions change, therefore, as for instance by the Lake coal shipping season ending or by the railroads becoming more efficient, little further increase in pig iron and steel production is to be expected, say beyond a 65 per cent operating rate.

CHANGES IN THE MARKET SITUATION

Market conditions, however, do not depict as great a scarcity of steel as appeared to exist a month ago. There have been some rather impressive changes in the market alignment. There is now very little demand for steel for late delivery, like December or the first quarter of the new year. Demand for early deliveries may be considered quite fair, for with the heavy buying that has marked the earlier portion of the year no very heavy tonnage of prompt steel should be expected as market demand at this time.

Since this is just the time of year when the steel market should stiffen if underlying conditions warrant a stiffening at all, the lightness of inquiry for forward delivery and the earlier deliveries obtainable at premium prices are significant. There seems to be a clear prospect that delivery premiums will disappear within the not distant future, perhaps in a month, leaving the whole market at the level now ruling for late delivery. For the greater part, this means simply the prices to which the Steel Corporation has lately adhered.

PROSPECTS FOR 1923

The common view is that there is a large volume of business to be done for 1923 delivery, industrial prospects being distinctly promising. Buyers and sellers of steel have never experienced difficulty in reaching a price basis when there was actual business to be done. With large business in prospect for 1923, a settling basis will no doubt be developed according to circumstances, either at present basis prices, ignoring delivery premiums now ruling, or at slightly lower prices. At the most, no great decline is to be expected. Present prices, for late delivery, average about $9 a ton above the market at its low point early in the year. Mills are unlikely to be willing again to go so near the cost line as at that time, while costs, on account of wage and fuel conditions, are up about $5 a ton.

According to delivery, price ranges in general are as follows: Bars, 1.90@2.25c.; shapes and plates, 2@2.25c.; sheets, 3.35@3.50c.; nails, $2.60@$2.75. Small lots of sheets seem to be bringing 3.75c. for very prompt shipment, but a good order for say 30 days' shipment could probably be placed at 3.50c. without difficulty.

Mills requiring box cars for shipping product have been short for some time, and a little steel has accumulated. Open top cars have now become scarce at some plants, resulting in slight accumulations of steel. Embargoes against shipment to one point or another are frequent and vexatious not simply to the consignee but also to the shipper.

PIG IRON MARKET

The pig iron market remains more or less stagnant. Only in an occasional instance has a merchant furnace been able to resume operations. A little Connellsville coke has been picked up, several brands having to be mixed, while the price is very high. In occasional instances furnaces are resuming on byproduct coke, but in general the increased supply of coal to byproduct ovens results simply in the operation of steel works furnaces.

Plainly pig iron prices are too high relative to the position of possible consumers, the result being a stagnant market, while attempts to buy large tonnages would merely send prices up. In basic iron there has been no defined market for some time, $30 valley being mentioned as a nominal quotation. It is doubted whether any steel works is in position to pay this price, while there are practically no offerings by merchant furnaces. There are some indications that steel works will offer basic iron in the market, on account of their steel orders not being able to absorb all their possible pig iron production. Bessemer remains quotable at $34 valley, and foundry on the basis of say $35 or $36 valley.

COKE AND COAL

Connellsville coke has stiffened in the week, being quotable now at $11@$12 for furnace and $13@$13.50 for foundry.

The Pittsburgh district coal market is a trifle easier. Indifferent grades of steam coal go at $4@$4.50, high-grade steam and gas coal being $4.50@$5. Good grades of domestic 1¼-in. lump stand at $5.25, this being the regular price of the Pittsburgh Coal Co.

STEEL SCRAP

Heavy melting steel scrap has undergone a sharp advance, having sold at $21.50, delivered in the Pittsburgh district, while it is thought that some Youngstown consumers have paid $22.50. Of late the Youngstown market has averaged nearly if not quite $1 above the Pittsburgh market. Demand is developing for cast scrap in charging box sizes. As high as $23.50 has been paid by foundries for cupola cast, and if steel works buy in such tonnages as would be natural the foundries will be confronted with higher prices still.

Soft steel bar shapes	2.80	2.80
Soft steel bands	3.40	3.40
Plates, ¼ to 1 in. thick	2.90	2.90

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

DEMOPOLIS—The Gulf States Portland Cement Co. is planning for the erection of an addition to its plant at Spocari, Ala., to double, approximately, the present capacity of 1,200 bbl. per day. Plans will be prepared at an early date.

MONTGOMERY—The Excelsior Brick Co. is planning for the rebuilding of the portion of its plant, recently destroyed by fire with loss of about $35,000, including equipment.

Arkansas

GRAVETTE — The Spees Vinegar Co., Kansas City, Mo., is arranging a list of equipment for installation at its local plant, to include a hydraulic press, drying machinery and other primary apparatus. A new power house will be constructed at the mill.

Delaware

SOUTH WILMINGTON—The Wilmington Sugar Refining Co. is arranging for the early resumption of work on its new local refining plant, held in abeyance for a number of months past, and proposes to push the main works to completion. The plant will comprise a number of buildings, and is estimated to cost in excess of $750,000, including machinery. Armstrong & Latta, Land Title Bldg., Philadelphia, Pa., are engineers and contractors.

Florida

DADE CITY—M. F. Ackerman, Dade City, has preliminary plans under way for the organization of a company for the establishment and operation of a new plant for the manufacture of bricks and other burned clay products. A site for the proposed works has been selected.

Georgia

COLUMBUS — The Dixie Brick Co. has commenced the installation of new equipment at its plant for increased production in a number of departments. J. E. Minter is secretary and general manager.

COLUMBUS—James H. Palmer & Co., Inc., Columbus, Ga., has been incorporated with a capital of $10,000, to manufacture fertilizer products. The incorporators are A. Drane and James H. Palmer, Columbus. The last noted represents the company.

Indiana

HAMMOND—Fire, Sept. 7, destroyed a section of the local plant of the Inland Steel Co., with loss estimated at $50,000, including machinery. It is expected to rebuild at an early date.

INDIANAPOLIS—The Crown Chemical Co. has acquired the 4-story building at the northwest corner of Pennsylvania and Georgia Sts., known as the Hurst Bldg., 60x110 ft., and will occupy for a new plant. It was obtained for a consideration said to be $100,000. The company will remove its present works at 433-35 East South St., and will utilize the structures at the latter location as warehouses in the future. Arrangements have been made for a change of name to the Boncilla Laboratories. John M. Price is president and general manager; and J. S. Judy, vice-president and treasurer.

Louisiana

NEW ORLEANS—The Loyola University has plans in preparation for the erection of a new 4-story chemistry building, 60x200 ft., and plans to call for bids early in October. It is estimated to cost close to $250,000, including equipment.

NEW ORLEANS—The M. Augustin Paint & Glass Co. plans for the rebuilding of its plant at 612 Jerome St., recently destroyed by fire, with loss estimated at close to $200,000.

NAPOLEONVILLE—The Godchaux Sugars, Inc., 527 Canal St., New Orleans, has tentative plans under consideration for the rebuilding of the portion of its local sugar-refining plant, known as the Elm Hall Refinery, destroyed by fire, Sept. 5, with loss estimated in excess of $1,500,000, including machinery, buildings and stock.

Maryland

BALTIMORE—The United States Industrial Chemical Co., Fairfield Rd., has filed plans for the erection of a 1-story works addition, 21x35 ft.

BALTIMORE — The Security Cement & Lime Co., Equitable Bldg., is perfecting plans for the proposed enlargement of its cement mill at Security, Md., to increase the capacity from 950,000 to 1,400,000 bbl. per year. Additional buildings will be erected and machinery installed. To provide for the expansion, the company has disposed of a note issue of $300,000. Loring A. Cover is president.

BALTIMORE—The Baltimore Water Paint Co. has acquired the factory property of the Crown Cork & Seal Co., on Eastern Ave., between 11th and 12th Sts., for a consideration said to be $25,000. The property consists of three buildings, which will be remodeled and improved for a plant for the new owner. It is planned to install additional equipment to cost, with building improvements, about $30,000. The new works are expected to be ready for service early in December.

Massachusetts

NATICK—The Griess-Pfleger Tanning Co., 179 South St., Boston, has completed plans for the erection of a new 1-story leather tannery, 180x320 ft., on local site, recently acquired on Washington St. Work will be inaugurated at an early date. Haven & Hopkins, 40 Court St., Boston, are engineers.

CAMBRIDGE—The Boston Woven Hose & Rubber Co., Hampshire St., has awarded a contract to William T. Reed, 201 Devonshire St., Boston, for the erection of a 1-story plant addition 43x85 ft. The John O. DeWolf Co., 45 Bromfield St., Boston, is engineer.

Missouri

SPRINGFIELD—The Southwestern Tanning Co., 214 Holland Bldg., W. R. Wolfe, head, recently organized, has plans under way for the construction of a 1-story leather tanning pant, 100x135 ft., at 500 West Commercial St., estimated to cost about $16,000, exclusive of equipment. Earl Hawkins & Co., 400 McDanniel Bldg., are architects.

New Jersey

NEWARK—The Miner-Edgar Co., Blanchard St., manufacturer of chemical products, has filed plans for the erection of a new 2-story plant addition, 40x144 ft., estimated to cost approximately $40,000. Work will be placed in progress at once.

TRENTON—The Magnetic Pigment Co., 603-13 Cass St., has awarded a contract to the N. A. K. Bugbee Co., Trenton, for the erection of an addition to its plant for the manufacture of metallic pigments, estimated to cost approximately $50,000. It is planned to have the structure ready for equipment at an early date.

NEWARK—The American Tallow Co., Plum Point Lane, has filed plans for the construction of a 1-story plant addition, 35x60 ft.

HACKETTSTOWN—The Alphano Humus Co., manufacturer of fertilizer products, is reported to be planning for the rebuilding of the portion of its plant, destroyed by fire, Sept. 4, with loss estimated in excess of $50,000, including equipment and stock.

TRENTON—The Essex Rubber Co., Beakes and May Sts., manufacturer of general rubber specialties, has plans nearing completion and will soon take bids for the erection of a new 2-story addition. J. Osborne Hunt, 219 East Hanover St., is architect.

NEWARK—The Verona Chemical Co., 26 Verona Ave., is reported to be planning for the rebuilding of the portion of its plant, destroyed by fire recently with loss estimated in excess of $50,000.

CAMDEN—Fire, Sept. 9, destroyed a portion of the plant of the Keystone Leather Co., 17th and Carman Sts., with loss estimated at close to $50,000, including drying and other equipment. The two upper floors of a 4-story building were demolished.

New York

MINEOLA—George M. Murray, Garden City, L. I., has acquired property at the Merrick Rd. and the Long Island Railroad, for the erection of a new 1-story chemical works. Plans will be prepared at an early date.

North Carolina

WILMINGTON—The Southeastern Chemical Co., Charlotte, N. C., has acquired a local building for the establishment of a new branch plant for the manufacture of chemical specialties from pine byproducts. Machinery will be installed at an early date and operations inaugurated. Forrest A. Johnson heads the company.

Ohio

AKRON—The General Tire & Rubber Co. has preliminary plans in progress for enlargements in its plant to double, approximately, the present output of about 2,500 tires a day. It is proposed to have the extension equipped and ready for service by the first of the year.

ALLIANCE—The Crescent China Co., affiliated with the Sebring Pottery Co., Sebring, Ohio, has work under way on a new plant for the manufacture of fine chinaware, to comprise a main 1-story pottery and seven kilns. It is expected to have the plant ready for the equipment installation at an early date. The H. K. Ferguson Co., Euclid Ave., Cleveland, is architect and engineer. S. Morley is president and general manager.

Oklahoma

POTEAU — George F. Collins, Sapulpa, Okla., has acquired the local plant of the Hutton-Bates Glass Co., manufacturing bottles and other containers. The new owner will continue the operation of the plant and plans for a number of extensions and improvements, including the installation of additional equipment. Possession will be taken at once.

PONCA CITY — The Marland Refining Co. has plans in progress for extensions and improvements at its local oil refinery to increase the capacity from 6,000 to 14,000 bbl. of finished products per day. Additional machinery will be installed. It is also planned to construct an addition to the storage and distributing plant, including the installation of new steel tanks to bring the capacity to about 1,920,000 bbl. A new waterworks system will be installed to serve the plant property and vicinity. The expansion is estimated to cost close to $1,500,000.

PICHER — The Eagle-Picher Lead Co. is said to have plans under consideration for the rebuilding of the portion of its local works, destroyed by fire recently, with loss of about $25,000.

PAWHUSKA—The Chamber of Commerce is formulating plans for the establishment of a local plant for the manufacture of glass products. It is said that a company will be organized to operate the works.

Pennsylvania

BETHLEHEM—The Lehigh Valley Industrial Alcohol Co., recently organized under state laws, has plans under way for the erection of a new local plant for the manufacture of industrial alcohol, fusel oil, carbonic acid, potash and kindred specialties. The initial works will give employment to about 35 men. A site for the factory has been selected. Edward F. Reilly, Bethlehem, is treasurer; and Freeman H. Moyer, Allentown, vice-president.

CONSHOHOCKEN—The Ruth Glass Co. has work under way on the rebuilding of its mill, destroyed by fire a number of months ago. It is expected to resume operations at an early date.

READING—Samuel H. Bell, Reading, is selecting local property for the manufacture of inner tubes for automobile tire service and other rubber products. A similar plant now being operated in a neighboring locality will be removed to the new site, and the present equipment considerably increased.

PAXTONVILLE—The Paxton Brick Co. has tentative plans under consideration for the

rebuilding of the portion of its local plant, destroyed by fire, Sept. 11. Several kilns and buildings were demolished.

South Carolina

FLORENCE—The Florence Gas & Fuel Co., recently organized with a capital of $100,000, is planning for extensions and improvements in its local plant, lately acquired. New compressors, purifiers, boilers and other equipment will be installed, estimated to cost in excess of $30,000. M. D. Lucas is president.

South Dakota

RAPID CITY — The South Dakota State Cement Co., Pierre, S. D., has plans under way for the construction of a new plant at Rapid City, to include a number of mills, power plant and other operating buildings, estimated to cost close to $1,500,000, including machinery. J. C. Buckbee & Co., 38 South Dearborn St., Chicago, Ill., are engineers. A. C. Hunt is secretary and treasurer.

Tennessee

KNOXVILLE — W. J. Savage & Co,. 912 West Clinch Ave., manufacturer of brick and other burned clay products, are planning for the erection of an addition to their plant, to cost about $25,000. Additional equipment will be installed.

KINGSPORT—The Mead Fiber Co., manufacturer of pulp soda and kindred products, has preliminary plans under way for the erection of a new local plant for the manufacture of fiber and paper products. The initial works will consist of three brick and steel mills, equipped for an output of about 35 tons per day. The plant is estimated to cost close to $1,000,000. J. H. Thickens is general manager.

Texas

HOUSTON—The Great Lakes Western Refining Co., operating the plant of the Port Houston Refining Co., recently acquired, has plans under way for the construction of a new oil refinery, with initial capacity of about 3,500 bbl. per day. It is planned to commence work at an early date.

EL PASO—The Dodson Cement Products Co., Dallas, has tentative plans under consideration for the erection of a new plant at El Paso, on site recently selected, estimated to cost about $65,000.

BURKBURNETT—The Revere Oil Co., Fort Worth, is said to be planning for extensions and improvements in the oil-refining plant at Burkburnett, recently acquired from the Burk-Tex Production Co. The present refinery has a capacity of about 4,000 bbl. per day, and this will be increased.

DALLAS—The Trinity Paper Mills Corporation, operating a small mill at Commerce, Tex., is perfecting plans for the erection of a new paper mill in the vicinity of Dallas, for the manufacture of fine papers, using cotton linters as raw material. The plant is estimated to cost close to $400,000, including machinery. The company is capitalized at $6,000,000. J. V. Webb is president, and A. H. Davidson, treasurer.

Virginia

LEXINGTON — The board of directors of the Washington & Lee University will take bids early in October for the erection of the proposed new chemistry building at the institution, estimated to cost about $150,000. Flournoy & Flournoy, 306 St. Paul St., Baltimore, Md., are architects.

WINCHESTER—The Snapp Foundry, Inc., recently organized with a capital of $50,000, will take over the local foundry heretofore operated under the name of the Snapp Co. The new company will specialize in the manufacture of a general line of castings, and contemplates plant improvements. C. Arthur Robinson is secretary.

West Virginia

PARKERSBURG—The General Porcelain Co. is completing plans and will soon commence the erection of a new 1-story plant addition, 65x225 ft., estimated to cost about $25,000. It will be equipped for general production.

Wyoming

CHEYENNE—The Mammoth Oil Co., recently organized under Delaware laws with a capital of $200,500,000, as a subsidiary of the Sinclair Consolidated Oil Corp., 45 Nassau St., New York, N. Y., will operate in the Teapot Dome Fields, lately acquired from the government under lease. The new properties will be improved with refineries, storage and distributing plants, and constitute a total of about 9,000 acres.

Industrial Developments

PAPER—The International Paper Co., New York, is maintaining full production at its different mills in New York and Canada, and new plants, recently completed, are giving employment to a full working force at close to capacity.

The Eastern Mfg. Co., Bangor, Me., is operating at capacity at its pulp and paper mills. During the past few weeks orders for paper have been in excess of production, and pulp shipments have been the largest in many months past. An oil-burning system is being installed to insure continuous operation.

The Spanish River Pulp & Paper Co. and the Lake Superior Paper Co., affiliated, Toronto, Canada, are operating at close to normal at their mills, with regular working force. It is expected to maintain the present basis of production for an indefinite period.

RUBBER—The Goodyear Tire & Rubber Co., Akron, O., is running at full capacity at its Canadian mills, under a 3-shift schedule, 8 hours each. It is said that present orders will require the maintaining of 24-hour plant operation for an indefinite period.

New production records were established by rubber factories at Akron, O., during August, and September operations are being continued on the same basis. The Firestone Tire & Rubber Co. is running on a basis of 26,000 tires a day; the Goodyear Tire & Rubber Co. is maufacturing 22,000 tires daily; the Goodrich Tire & Rubber Co., the Mason Tire & Rubber Co. and the Miller Rubber Co. are all running full.

Owing to the expected curtailment in Ford automobile production, the Goodyear Tire & Rubber Co., Akron, O., has reduced operations at its Plant No. 2, devoted to tire manufacture for such cars, to a 4-day week schedule Heretofore the plant has been running three shifts per day on a 5½-day week.

GLASS — The Scott-Warner Glass Co., Stroudsburg, Pa., is completing the rebuilding of its local plant, destroyed by fire a number of months ago, and plans to place the factory in operation at an early date, giving employment to close to 100 men.

The Johnston Glass Co., Hartford City, Ind., is maintaining active production at its local plant, giving employment to a regular working force. The wage schedule has recently been advanced 25 per cent. The company specializes in window glass manufacture.

The Pittsburgh Glass Sand Co., Pittsburgh, Pa., is running full at its two plants at Mapleton, near Lewistown, Pa. A wage increase has been granted, effective Sept. 4, with common labor receiving $3.50 a day under the new schedule and corresponding increases in other departments. The Pennsylvania Glass Sand Co., operating in this same district, has also made similar wage increases at its plant.

The Owens Bottle Co., Toledo, O., has recently advanced production at its plant, following improvements made for this purpose. A large working force is being employed.

Glass plants at Pittsburgh, Kane and other points in western Pennsylvania are planning to advance production to a third shift working day, under full 24-hour operation before the close of the fall season, the increase being based on the volume of incoming orders.

OIL—The Pure Oil Co. has resumed operations at its refinery near Ardmore, Okla., following a shut-down of several months. It is expected to advance the output gradually to maximum, wken employment will be given to about 75 men.

The Mexican Petroleum Co, New York, N. Y., is increasing production at its Mexican plants. During August a total of 4,000,000 bbl. of oil was produced, as compared with 3,500,000 bbl. in the preceding month.

IRON AND STEEL—The Brier Hill Steel Co., Youngstown, O., has blown in another furnace at its plant, making the third unit now in blast.

The A. M. Byers Co., Girard, O., is planning for the early resumption of operations at its local blast furnace, which has been shut down for a number of weeks. The puddling mill has started up. About 1,200 men will be empoyed following the adoption of a full-capacity schedule.

The American Sheet & Tin Plate Co., a subsidiary of the United States Steel Corp., is arranging for the immediate resumption of eight hot mills at the local plant, following a month's shut-down due to fuel shortage.

The Eastern Rolling Mill Co., Baltimore, Md., specializing in the manufacture of steel sheets, is running at close to 100 per cent at its plant, giving employment to about 1,200 operatives, or approximately double the number at the works at the beginning of the year. The wages of common labor have been increased 20 per cent, or from 25 to 30 cents an hour, with 8-hour working day. It is said that orders on hand insure full capacity for many months to come.

The Republic Iron & Steel Co., Youngstown, O., has blown in another blast furnace at its mills, making the fourth unit on the active list. Other departments of the works are advancing production.

The Trumbull-Cliffs Iron Co., Youngstown, O, has blown in its blast furnace, following curtailment for a number of weeks due to coal and coke shortage.

The Youngstown Sheet & Tube Co., Youngstown, O., has lighted another blast furnace at its local plant and made additions in the working force. Further increases will be made at an early date.

MISCELLANEOUS — The New York & Pennsylvania Co., Johnsonburg, Pa., has resumed operations at its whiting plant and soda mill, following a suspension for about a month past on account of fuel shortage. Approximately 125 men are employed in the two mills.

The Standard Sanitary Mfg. Co., Tiffin, O., has been forced to curtail operations at its local pottery, due to a strike of about 100 men in protest against the employment of several non-union molders at the plant.

The Atlas Portland Cement Co., Northampton, Pa., is running full at its large mills in this district, and has recently announced a general wage increase affecting all employees. The Lehigh Portland Cement Co., Allentown and Coplay, Pa., has also advanced the wage schedule at its mills. Capacity output is being maintained at the latter plants.

The New Jersey Zinc Co., Palmerton, Pa., is giving employment to close to normal working force at its local plant, under full-time production. A general wage increase has recently been placed into effect.

The International Nickel Co., New York, has resumed operations at its plant at Coppercliff, Ont., following a suspension of 18 months. The initial production will be on a basis of about one-third of maximum output, giving employment to about 650 men under a two-shift operating schedule, 18 hours per day total. The company is also operating its refining plant at Port Colborne, and shipments are being made from the Creighton mines. All refined production is being sent to the new rolling mills at Huntington, W. Va.

New Companies

THE NATIONAL RUBBER CO., Los Angeles, Calif., has been incorporated with a capital of $100,000, to manufacture rubber products. The incorporators are E. J. Chambers and R. H. Watts, Long Beach, Calif., and Harry W. Mahan, Room 618, O. T. Johnson Bldg., Los Angeles. The last noted represents the company.

H. O. BOEHME, INC., New York, N. Y., care of P. C. Schnitzler, 35 Nassau St., representative, has been incorporated with a capital of $25,000, to manufacture metallic compounds and affiliated products. The incorporators are H. O. Boehme and K. Braun.

THE HOOSIER FERTILIZER CO., 1400 North Halsted St., Chicago, Ill., has been incorporated with a capital of $40,000, to manufacture fertilizer products. The incorporators are Maurice and Samuel L. Sarnatzky.

THE ARION STEEL CO., Boston, Mass., has been incorporated with a capital of 500 shares of stock, no par value, to manufacture steel products. Harry F. Arion, 83 Lawrence St., Medford, Mass., is president and treasurer.

THE ARROW CHEMICAL CO., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Walter A. Beers, William A. and Edward A. Schilling, 763 Broad St. The last noted represents the company.

THE INDIANAPOLIS SOAP CO., Indianapolis, Ind., has been organized under state laws to manufacture soaps, washing powders, etc. The incorporators are Jesse M. and Sidney F. Daily, both of Indianapolis.

THE FALCONER PLATE GLASS CORP., Falconer, N. Y., care of Jackson, Manley & Herrick, attorneys, Jamestown, N. Y., representative, has been incorporated with a

capital of $150,000, to manufacture glass products. The incorporators are E. A. Peterson, B. H. Tefft and S. O. Merriman, Falconer.

THE M. E. FOLSOM FLOOR & WALL TILE Co., Union Hill, N. J., has been incorporated with a capital of $10,000, to manufacture and deal in ceramic floor and wall tile and affiliated products. The incorporators are M. E. Folsom, Frederick Brunning, Jr., and William Hinderks, 509 Gardner St., Union Hill. The last noted represents the company.

THE CALEDONIA OIL CORP., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $500,000, to manufacture petroleum products.

THE SHERMAN OIL MILL, INC., Sherman, Tex., has been incorporated with a capital of $175,000, to manufacture petroleum products. The incorporators are J. H. Wharton, Thomas Forbes and N. A. Birge, all of Sherman.

THE DETROIT TYLITE CO., Detroit, Mich., has been incorporated with a capital of $50,000, to manufacture composition tile and kindred building products. The incorporators are J. H. McIntyre, W. F. Rue and Frederick S. Beard, 2460 Central Ave., Detroit. The last noted represents the company.

THE INDEMAND PRODUCTS CORP., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del, representative, has been incorporated with a capital of $100,000, under state laws, to manufacture rubber products.

THE STAMFORD COTTON OIL CO., INC., Stamford, Tex., has been incorporated with a capital of $120,000, to manufacture cottonseed oil products. The incorporators are W. A. Bennett, L. W. and C. L. Jones, all of Stamford.

THE MILLIKEN BRICK CO., Pittsburgh, Pa., is being organized by Homer A. Milliken and John F. Baldwin, to manufacture brick and other burned clay products. Application for a state charter will be made on Oct. 2. The company is represented by R. A. McCrady, 1430 Park Bldg., Pittsburgh.

THE MEMPHIS COTTON HULL FIBRE CO., Memphis, Tenn., has been incorporated with a capital of $15,000, to manufacture fiber products. The incorporators are Walter Wolf, A. J. V. Ware and S. S. Dent, all of Memphis.

THE GLIDDEN OIL CO., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $1,000,000, to manufacture petroleum products.

THE YONKERS SOAP MFG. CO., care of D. Dorfinkel, attorney, Yonkers, representative, has been incorporated with a capital of $5,000, to manufacture soaps, washing powders, etc. The incorporators are H. Lerner, N. and D. J. Ressler, all of Yonkers.

THE SOUTH BEND GLASS WORKS, INC., South Bend, Ind., has been incorporated with a capital of $25,000, to manufacture glass products. The incorporators are Frank Haynes, Clarence K. and Herman H. Beyrer, all of South Bend.

THE DURATEX CO., 768 Frelinghuysen Ave., Newark, N. J., has been incorporated under state laws with a capital of $1,900,000, to manufacture imitation leather products. The incorporators are the officials of the company of the same name, now operating a plant at the location noted.

THE MERCER REFINING CO., Franklin, Pa., has been incorporated with a capital of $75,000, to manufacture refined oil products. W. C. Hastings, Franklin, is treasurer and representative.

THE CHEMICAL SPECIALTY CO., 380 Main St., Pawtucket, R. I., has filed notice of organization to manufacture chemicals and chemical byproducts. Richard Rouse heads the company.

THE LOUIS HUETWOHL BRASS FOUNDRY, INC., Brooklyn, N. Y., care of I. Phillips, 303 West 122nd St., New York, representative, has been incorporated with a capital of $20,000, to manufacture brass, bronze and other metal castings. The incorporators are G. and L. Schimper, and Louis Huetwohl.

THE SIMPLEX PETROLEUM CO., Long Beach, Calif., has been incorporated with a capital of $200,000, to manufacture petroleum products. The incorporators are Albert Stephens, H. Earl Hardy, and Vern Dumas, 1155 Burnett St., Long Beach. The last noted represents the company.

THE BROWN SOAP CO., Indianapolis, Ind., has been incorporated with a capital of $10,000, to manufacture soap products. The incorporators are Arthur B. Brown, A. L. Coburn and Gilbert McGaughey, all of Indianapolis.

THE BUTTERS MFG. CO., New York, N. Y., care of A. J. Lindsay, 43 Cedar St., representative, has been incorporated with a capital of $75,000, to manufacture chemicals and chemical byproducts. The incorporators are W. C. Findley and W. A. Levy.

THE ROONEY & ELY FERTILIZER CO., Jersey City, N. J., care of the Corporation Trust Co., 15 Exchange Place, Jersey City, representative, has been incorporated with a capital of $10,000, to manufacture fertilizer products. The incorporators are C. J. Skinner and W. J. Edelman.

THE JONES & LEIGH MFG. CO., New York, N. Y., care of L. I. Geber, 291 Broadway, representative, has been incorporated with a capital of $100,000, to manufacture paper products. The incorporators are G. L. Leigh, W. A. Simon and H. A. Jones.

THE MERION MAGNESIA CO., Port Kennedy, Pa., has been incorporated with a capital of $5,000, to manufacture magnesia products. Clayton Ullman, Phoenixville, Pa., is treasurer.

THE WALTER L. JOHNSON CO., Endicott, N. Y., has been incorporated with a capital of $12,500, to manufacture leather products. Walter L. Johnson, Endicott, heads the organization, and represents the company.

THE UNITED STATES PACKING & LUBRICATING CO., Philadelphia, Pa., care of the Capital Trust Co. of Delaware, Dover, Del., representative, has been incorporated under Delaware laws, with capital of $600,000, to manufacture lubricants and kindred products. The incorporators are Alfred E. George, D. J. Mullins, Philadelphia; and Francis J. MacDonald, Ardmore, Pa.

Manufacturers' Catalogs

THE SCHUTTE & KOERTING CO., Philadelphia, Pa., describes in bulletin 8-G the new Schutte regrinding swing gate valve, which is a straightway closing valve designed for steam pressures up to 300 lb. per sq.in. and temperatures up to 750 deg. F. The company announces that this valve offers no obstruction to the steam flow or change of direction, and that the outstanding feature is that the valve disk is readily accessible for regrinding purposes without dismounting the valve.

THE W. W. SLY MFG. CO., Cleveland, O., is issuing a bulletin, S-90, entitled "Dust—A Loss and a Gain." It contains new and interesting matter concerning the collection of industrial dust.

THE BRISTOL CO., Waterbury, Conn., has ready for distribution a 68-page catalog (No. 1401) devoted to Bristol's pyrometers. The catalog is profusely illustrated and contains very valuable condensed information on this subject.

THE B. F. STURTEVANT CO. of Hyde Park, Boston, Mass., has just issued a new 72-page engineering bulletin on Pneumatic Collecting and Conveying. It contains 33 pages of pictures and diagrams, 17 pages of useful tables—how to find the size of fans, the suction, volume, r.p.m. and horsepower for any system, cubic feet of air handled per minute, size of pipe and ducts used, and various other valuable tables. Data are also given on dust collecting from grinding and polishing machines, tumbling barrels, sand blast machines, coal breakers, shoe machinery and the removal of fumes, gases, etc. In addition, there are parts on the conveying of pulverized coal, fibrous materials, coffee, ashes, wool, wood chips, etc. It is a most comprehensive treatise on pneumatic collecting and conveying systems.

THE RAYMOND BROS. ENGINEERING CO., Chicago, Ill., calls attention to a new catalog on "Rayco Pulverized Coal Systems—Their Design, Installation and Operation." This attractive catalog, which is well illustrated, has chapters on engineering service, fuel economy, essentials to successful results, records of results and savings, growth in use of powdered coal, combustion efficiency, character of powdered coal flame, variety of applications, plan of typical plant, crushing equipment, drying equipment, pulverizing equipment, distributing equipment, burners, tables of capacities, detail parts, individual unit, installations and data sheets.

THE ELECTRIC FURNACE CO., Salem, O., has issued a folder illustrating some of the types of electric enameling, annealing and heat-treating furnaces it has installed in the last few years. Another folder, on the "Baily Electric Furnaces" tells what nonferrous alloys the company is melting, and what products it is producing.

Industrial Notes

THE NORWALK IRON WORKS CO. announces that it has merged with it the Automatic Carbonic Machine Co. of Peoria, Ill., the plant and equipment of which company is being moved to South Norwalk, Conn.

C. E. Reese, editor of the *Gas Engineering & Appliance Catalog* and associate editor of the *Gas Age-Record*, has joined the stoker sales department of the Westinghouse Electric & Mfg. Co., at South Philadelphia. He was previously cadet engineer and combustion engineer with Henry L. Doherty & Co. and assistant engineer of the Illinois Public Utilities Commission. Mr. Reese will work with G. A. Sacchi, manager of the stoker sales department and R. R. Davis, manager of the department of publicity at East Pittsburgh.

THE U. S. ELECTRO GALVANIZING CO. announces change of name to the U. S. Galvanizing & Plating Equipment Corp., with main office and factory at 32 Stockton St., Brooklyn, N. Y.

THE MERRIMAC CHEMICAL CO., Boston, Mass., announces the following appointments: Sales manager, William M. Rand; chief engineer, J. B. Rutter, and designing engineer, M. S. Maxim.

L. J. Krom has established an office at 50 Church St., New York City, for the purpose of carrying on a consulting, metallurgical and engineering practice which will be devoted to the production and consumption of metals and alloys.

Coming Meetings and Events

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN INSTITUTE OF MINING AND METALLURGICAL ENGINEERS is holding its 126th meeting at San Francisco, Calif., Sept. 25-29, 1922.

AMERICAN SOCIETY FOR STEEL TREATING will hold its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN WELDING SOCIETY will hold its fall meeting Oct. 2 to 5 at Chicago.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting Oct. 9 and 10, at the Hotel Wolverine, Detroit, Mich.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, 52 East 41st St., New York City: Oct. 6—American Chemical Society, regular meeting Oct. 13—Société de Chimie Industrielle, regular meeting. Oct. 20—Society of Chemical Industry, Grasselli Medal. Nov. 10—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting. Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting, May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

An Engineering Investigation Of the Muscle Shoals Project

THE decision of the Federated American Engineering Societies to make an impartial engineering investigation of Muscle Shoals and recommend what it considers the best method of handling this moot project will meet with the approval of all who sincerely want to get a fair appraisal of the relative value of the several plans that have been proposed. Shall the government construct and operate this great power development? Shall it be leased to Mr. FORD? Shall it be turned over to a private concern like the Alabama Power Co. to be developed under the terms of the federal water power act? The changes have been rung on each of these proposals, with the result that partisan groups have arisen here and there who espouse their preferences without regard to the national welfare. Hearings have been held and investigations have been made in such number that it seems unlikely that any essential facts have been overlooked.

The great problem is to study and correlate the known data and to deduce therefrom a logical plan of procedure. This is the task to which the special committee of the Federated American Engineering Societies will devote itself. If, happily, the committee can reach a decision acceptable to the country, the Federation will have rendered a great national service. Further, it will have pointed the way to the solution of other great national problems before they have run the gantlet of Congressional committees and industrial promoters. In the case of Muscle Shoals it may put a damper on the aspirations of realty companies that are promoting town lots and holding out glittering hopes of fortune to those who follow their admonition to invest immediately, but this would be a calamity under which the country will endeavor to bear up if a solution can be found for the Muscle Shoals problem.

Reaching the Wrong Conclusion

SEVERAL YEARS AGO a large manufacturing concern bought, through the medium of a banking house, an option on a certain process. The corporation paid $10,000 for it. It was carefully worked out and ready for industrial operation. To adopt it would have involved the installation of some new equipment, but it promised material savings. Suddenly they declared that it was not what they wanted, charged up the sum paid for the option to profit and loss and would have nothing more to do with it. They would not even investigate adequately. They would not take as a gift an extension of the option; they were very drastic about it, and they "cut it out."

The process is in successful operation today, and they could easily have bought it outright and got all their money back from royalties without even using the process themselves, if they had wanted to do so.

Now in discussion lately with the banker who negotiated the sale, he said that the incident had been very instructive to him: that he had developed from it the slogan that even 100 per cent efficiency in a laboratory test means nothing in factory practice. Of course he assumed that the purchasing and refusing corporation had acted wisely; he thought they must know their business. But right there he was wrong. The corporation had no research establishment. Nobody on the board or among its executives had technical knowledge or a chemical background for their chemical business, and what really happened was that their advisory chemist was a sick man who condemned the process without more than a cursory glance at it. The process had already been carried out on a semi-commercial scale, and the only specific reason that we could discover why it was refused with such suddenness was that the consultant didn't like the idea and it meant changes in installation. There was nobody to check off the sick man, no one to argue with him. Consequently the manufacturers made a big mistake and the banker got the wrong slant on the whole subject.

The general reason why the process was not even critically examined and the corporation lost track of the whole thing was ignorance at the top. Nobody in authority knew enough chemistry in their chemical establishment to sense the principles which underlay the process. There are plenty more of just such chemical establishments in this country.

Our Knowledge Of Coal

TWO recent developments at the University of Illinois regarding our knowledge of the character and behavior of bituminous coal are worthy of special notice. Both of these developments have been made by Prof. S. W. PARR and his associates, who have not been content to follow the well-beaten paths of fuel research, but have gone exploring in virgin territory.

In one case the work has related to the structure of coal as affected by the oxygen content of the bituminic and cellulosic constituents. In this work PARR points out that the oxygen in the bituminic constituent apparently does not affect the binding power of that material for production of coke as one would expect, but that oxygen entering the cellulosic constituent does seem to affect the coke-forming power of the coal very materially. This information brings us one step closer to an understanding of what it is that causes some coals to form no coke, some to form only soft friable coke, others to form hard, strong coke of metallurgical value.

The other investigation has been carried out by LAYNG in association with Professor PARR. It is on

the softening point of coals and the point at which the plastic coal again hardens into a coke structure. It is too early as yet to forecast what this particular investigation will demonstrate, but the results promise to be very valuable in distinguishing between the oven performance of different fuel supplies.

These two investigations are noteworthy not alone because of the results which they have given or promise to give soon. They are conspicuous rather more because they represent a pioneer effort that has been all too long postponed. Coal is the most used raw material which nature provides to industry. Half a billion tons of it are used annually. Yet after generations of use we find ourselves still with practically no knowledge of the characteristics of coal constituents and without means for thoroughly intelligent discrimination between the coal from different sources. We have been content too long to use the approximate analysis which gives us only volatile, fixed carbon, ash and moisture, and the ultimate analysis which gives us the composition by the elements—carbon, hydrogen, oxygen, sulphur, nitrogen.

The heating value of the coal and the melting point of its ash have, to be sure, been used much by engineers to judge the value of the coal for boiler firing. But heretofore we have known nothing of the other significant characteristics, particularly with respect to the coking of a coal. It is to be hoped that Professor PARR and his associates will find opportunity rapidly to extend our knowledge in the fields which they have begun to till. But these fields are only a small fraction of the virgin territory that requires exploration and mapping. Other investigators will do well to consider the general scheme of investigation which PARR is following.

An Example of The Ruling Passion

THIS HAS TO DO with an able chemist who was installed as general superintendent of an important chemical works with permission to select his own staff. The concern bought in quantity only two raw materials which were obtained under contracts, so that two contracts per year were all that were needed. Nevertheless a purchasing agent was installed who had no technical knowledge whatever, and, while he was an agreeable young man, he could not be said to be of assistance or to earn his salary. It was necessary for him to ask questions about every requisition, and that took time. It did not save money.

During the nearly two years that our friend was in charge of the plant only one director ever visited it. All that the directors knew was what they got from monthly statements. When occasional inquiries came from them involving technical points, the superintendent dictated the replies, but they were made to appear as emanating from the vice-president in charge, who was not a technical man. This was a small affair, but it misrepresented the vice-president.

The concern had a hard and fast "system" about letters. In the early days the superintendent had considerable correspondence with the sales manager to meet specifications. The product was new, and selling required no little exposition that involved technical information. Individual salesmen, interested in their work, also wrote frequently to get points, and these were answered. In time all this was forbidden. All letters were to be addressed to the company, "attention of ——" at most, and were to be placed on the desk of the vice-president before they could go out, and directions were also sent to the salesmen not to communicate directly with the superintendent. This, of course, made the letters impersonal, and it cost the company the lively interest of the sales force.

Lately some new financial interests have come in. They want to be represented in the management as well as in the directorate. So a new general manager has been appointed to care for both the business and technological ends of the company's affairs. He has no technical training. The superintendent, after bringing on his family and purchasing a house, has been dropped for no other purpose, either intimated or even conceivable, than "economy." Of course that is not of general interest, but the concern is now blundering along making what are supposed to be pure chemicals without technical direction. That is of general interest. When will our bankers learn how foolish it is to put an unprepared and unskilled man in charge of complex scientific processes, because somebody who doesn't know anything about them has "sized him up and thinks he'll do"?

Chemistry in Agriculture In Great Britain

ELSEWHERE in this issue we tell of the development of turning cellulose into humus or farmyard manure worked out at the Rothamsted Agricultural Experiment Station at Harpenden, England. It was our privilege to spend a day there with Prof. H. E. ARMSTRONG of London, who has been for many years one of the trustees of the establishment, to walk over their fields with Sir E. JOHN RUSSELL, the director, and to spend some time in the laboratories with H. J. PAGE, the chief chemist, and others. The laboratory is divided into departments as follows, with a head for each, and assistants in number from one to six: Bacteriological, botanical, chemical, fermentation, antiseptics (with insecticides, etc.), physical, protozoological, statistical, entomological and mycological, Outside is the farm with experimental fields of about 350 acres under a manager and several assistants, and inside again is the library of 15,000 volumes, with librarian and secretarial staff.

The station was founded in 1843 by Sir J. B. LAWES, and Sir J. H. GILBERT was associated with him as director for nearly 60 years. LAWES died in 1900, GILBERT in 1901 and there succeeded them in the direction Sir A. D. HALL, who resigned in 1912, and Sir E. JOHN RUSSELL, who was appointed to succeed him.

The purpose of these notes is merely to indicate work in process. Of course, there are the famous fields of wheat, barley and roots, planted year after year with the same crops—for 81 years now with wheat—and subjected to varying treatments in the way of fertilizers. The old unfertilized field will scarcely give 10 bushels to the acre this year, but usually they get about 12. In their regular wheat fields, properly fertilized, they get, as the writer recalls, an average of about 45 bushels to the acre. Standard crops are grown, along with experiments to show farmers that they can get results as well as make experiments. The British farmer trusts his eye rather than statistics. We think we have met American farmers who showed that inclination also.

In the botanical laboratory Dr. BRENCHLEY and her assistants were working among other things on the

effect of boric acid on plant growth. Hearing of the misfortunes of American farmers who got borax along with their potash, the research began to see how much of this dread poison plants can stand. Working with "broad beans" (which we take to be field beans), the curious discovery was made that they must have it! Traces of borax are found in the beans and if they are grown in a medium from which borax is entirely absent, they develop part way both in branches and roots and then stop. Roots and stalks grow nubbly and cease to mature. One part in 2½ million is enough, but one part in 50,000 is endured. More than that is likely to act as poison. Barley, on the other hand, seems to thrive without borax. The research is not completed.

The unsatisfactory results from the use of phenol as an insecticide was ground for an investigation in the biological laboratory which brought out the remarkable fact that there is a species of micro-organism that thrives on phenol as its sole source of organic matter. Another thrives on benzene, another on toluene and still another on naphthalene.

Of course, work is in progress as to the wart disease in potatoes and another research has to do with the difference in fertilizing values of chloride and sulphate of potash respectively. The Germans furnish the sulphate and claim it is better. The French produce chloride and claim that it is as good. Differences in plant cultures are observed, but definite results have not yet been obtained.

Still another study has to do with the formation of humus in soil by green manuring. The statistical department is doing splendid work in making tables showing the effect of weather on crops under the same conditions, with records that go back for 80 years.

In the soil physics laboratory work is in process to determine water-holding qualities, shrinkage, expansion, cohesion and other physical properties under given conditions. Resistance determinations by means of a dynamometer attached to a plow and measuring the draw-bar pull of chalked and unchalked land showed an increase of 150 lb. and more on each plow when the soil was lacking in calcium carbonate. This is as pretty a note in colloid chemistry as we have come across for some time.

Mechanical Equipment And Human Contentment

IN HIS ARTICLE entitled "Increased Production Efficiency Means Good Material Handling" in our issue of August 30, J. G. HATMAN said: "Some of the effects of a well-designed, efficient handling system on the personnel of the manufacturing plants are . . . it enables the employee to work at his best, and hence command a high rate of pay. It takes the burden of physical labor from the laborer and makes him a brain-worker." This is the key to contentment at work, and contentment in work is the key to industrial progress. We have often said, and we expect to continue to preach the same gospel, that no amount of profits or dividends can atone for making men of wrath and misery out of a working staff. Of course there are large numbers of men who cannot work with their brains, but if an employer cannot bother to find out which men can and which cannot use their heads at work, he is himself incompetent and would better engage someone who knows more than he does to do the job.

We recall one large establishment which, before it was injured by high finance, was a veritable haven of contentment in which the competent manager put his stupid men into a yard gang. All that he required of them was to dig and push and pull under the direction of an intelligent foreman. That eliminated the unfit (for brain work) and yet did not throw them back on their relatives with all the distress such a procedure involves. This left him with a much higher average of intelligence for his labor staff within the works and provided that such hand workers could indeed be developed into brain workers. In order to prevent the exploitation of the unfit and the bringing down also of the fit to the same level, the labor unions have generally opposed any separation of this sort. But it is the only thing to do if highly developed workers are to be encouraged and a good esprit de corps maintained. A good man wants a chance to use his head and to improve his condition. The employer who cannot sense this and who can't provide for what the intelligent worker really needs is himself incompetent.

Productive and Unproductive Wealth

IN ROUND FIGURES the people of the United States are this year spending two billion dollars for new automobiles and three billion dollars for new dwelling houses and garages. The total of five billion is in the neighborhood of one-twelfth of the national income.

That this five billions of expenditure along these two lines is an important fact is proved very neatly by the amount of attention that has been given it. Everywhere it is being remarked that the automobile industry has had a wonderful revival; also that we are in "a great building boom." This constitutes proof that the condition is a remarkable one. Frequently the references are made for the purpose of proving a conclusion, as for instance that the country is very "prosperous." These ready-made conclusions are another matter. The point is that something big is going on.

The return for the five billions of expenditure represents actual wealth, except as it may depreciate from use or because the cost of replacement decreases. It is wealth this year just as the value of farm lands, or railroad cars, or carpets is wealth. All such items are in any proper inventory of the nation's physical wealth.

An important feature of this expenditure of one-twelfth of the national income is that it is upon property that has, in the last analysis, practically no earning power. Only to a relatively negligible extent will the automobile increase the productive power of their owners. Possibly the net result will be the other way, making the owners less disposed to work. As to the dwelling houses, their object is to increase comfort, not to increase production except as personal comfort and welfare affect production.

The great growth in the wealth of the United States has been due in large part to investment of savings in productive enterprises. The increase has been too rapid for it to represent a mere piling up of savings. The accumulation has been at something perhaps even better than compound interest. A compound interest accumulation would represent repeated investment of savings in productive enterprises.

When one-twelfth of the income is spent upon unproductive property, there is represented an abstraction from funds that would otherwise be invested in productive enterprises, in public service facilities, land reclamation, mine development and various other things. In view of this, one may well doubt whether the country is now in line to experience increases in total wealth in future comparable to the increases of the past.

Montreal Meeting American Electrochemical Society

Forty-second General Meeting Marked by Presentation and Discussion of Papers on Electrolytic Iron, Electrolytic Zinc and Electrolytic Nickel—Symposium on Industrial Heating by Electricity — Canadians Ideal Hosts

EDITORIAL STAFF REPORT

THE forty-second general meeting of the American Electrochemical Society was held at Montreal, Canada, Sept. 21, 22 and 23. The meeting was very well attended, over two hundred registering. The local committee, headed by H. W. Matheson and C. R. Hazen, spared no effort in making the electrochemists' visit one of the most entertaining and enjoyable in the annals of the society. A. R. M. MacLean headed the excursion committee and W. B. Woodland took care of the publicity. It was largely due to Mr. Woodland's efficient methods that the convention was so well advertised and in consequence well attended.

Besides the technical sessions, there were a number of social affairs which will always be remembered by those who participated. The outstanding social event was the visit at Shawinigan Falls, where R. A. Witherspoon and his committee were hosts. None but Witherspoon, with his irresistible humor and very efficient leadership, could have planned and conducted that luncheon and entertainment on the lawn of the Shawinigan Falls Inn.

Thursday Morning Sessions

The technical sessions were held at the Windsor Hotel. There was much animated discussion due to a strong representation by opposing factions. The manufacturers of apparatus claimed perfection in design and high efficiency in operation; the users of this apparatus, however, were all too anxious to point out what they considered inherent weaknesses of the product. The general impression gained was that even closer co-operation than practiced in the past was needed between designer and builder of electric ovens, furnaces and other apparatus on the one hand and the user or consumer of these on the other.

The first session, Thursday morning, was opened by President C. G. Schluederberg, of the Westinghouse company. He introduced Alderman Seyboldt, who welcomed the members of the society on behalf of the Mayor of Montreal and enumerated a few of the numerous attractions of the city. It was a surprise to many to learn that Montreal had the second largest harbor in North America, constructed at a cost of over $31,000,000. Prof. Robert Fulford Ruttan, of McGill University, past-president of the Society of Chemical Industry, extended a hearty greeting in the name of the chemists and engineers of Canada. "Your meeting in Canada," he said, "will help to emphasize the vast importance of the electrochemical industries to this country. As in the States so with us, many of the splendid researches undertaken during the course of the war have been abandoned and it requires a good deal of concerted effort to impress upon all parties concerned the absolute necessity of investigative work." Professor Ruttan's concluding remarks were: "I trust you will share with us in our good spirits."

The remainder of the morning session was devoted to papers and discussion on electrodeposition and the properties of the products.

ELECTROLYTIC IRON

Norman R. Pilling, of the Westinghouse research laboratory, gave an account of experiments he had carried out to ascertain in what way the properties of electroplated iron are subject to modification by simple heat-treatment. The initial effect of annealing is a very marked hardening, reaching a maximum at an annealing temperature of 300 to 400 deg. C. The corresponding scleroscope hardness number is 45. At the same time the initial brittleness is removed. Annealing at higher temperature results in progressive softening, consummated above the A_3 temperature (900 deg. C.). For complete and rapid softening, annealing at 900 deg. is necessary. The rate of decomposition of the unstable iron-hydrogen compound, which is assumed to be an essential component of electrolytic iron, was observed at different temperatures.

Mr. Pilling found that the compound is actively decomposing at a temperature as low as 90 deg. C. The maximum rate of decomposition occurs at about 200 deg., but complete decomposition and expulsion of hydrogen are not achieved until the A_3 temperature is exceeded. The increase in rate of evolution above 500 deg. appears to be due to a slow release of hydrogen, by diffusion from the interior of the larger particles or crystals, rather than due to a secondary reaction. The loss in weight due to the escaping hydrogen amounted to 0.11 per cent.

A series of microphotographs were shown indicating a close relationship between physical properties and structure. The original deposits are composed essentially of closely packed needle-like crystals, generally directed perpendicular to the surface of the cathode. As

RIVER FRONT, MONTREAL

he annealing temperature is raised, a gradual change in tructure is discernible and at 900 deg. the well-known A_3 transformation occurs.

Discussion

Mr. Pilling's paper was discussed and commented pon at length. Henry Howard of Cleveland suggested hat it might be possible to determine the hardness of he iron-hydrogen compound. David B. Rushmore, of Schenectady, referred to the commercial development of lectrolytic iron in France and inquired as to possibilities of a similar development in America. H. M. Williams, of the General Motors Research Corporation, referred to experiments on carburizing electrolytic iron deposited on worn machine parts. J. D. Alley, of Pittsburgh, pointed out that such carburizing was generally not necessary, since the deposits could be made hard enough electrolytically. Colin G. Fink, of New York, questioned whether such deposits would not be too brittle, and William Blum referred to the brittle nickel deposits due to the presence of hydrogen. Eliminating he hydrogen produced a soft flexible nickel deposit.

Preparation and Mechanical Properties of Vacuum Fused Alloys of Electrolytic Iron With Carbon and Manganese

Robert P. Neville and John R. Cain, of the Bureau of Standards, Washington, next reported upon "The Preparation and the Mechanical Properties of Vacuum Fused Alloys of Electrolytic Iron With Carbon and Manganese." An extensive series of very pure alloys of electrolytic iron, carbon and manganese were prepared, the melting carried out in an Arsem vacuum furnace, thus eliminating as much as possible the influence of gases on the properties of the alloys. The ranges in chemical composition of the alloys were from 0.0 to 1.6 per cent carbon and from 0.0 to 1.6 per cent manganese. In amounts below approximately 1 per cent C the ultimate strengths of the alloys were increased by carbon, at an approximate average of 1,000 lb. per square inch for each 0.01 per cent carbon introduced. The increase in hardness due to carbon was from 1.8 to 2.6 Brinell numbers for each 0.01 per cent C, the rate being larger as the manganese contents increased. Reduction of area and elongation of pure iron were 82.5 and 40.5 per cent respectively. With the addition of carbon these values were rapidly and regularly decreased. Manganese increased the ultimate strengths of the alloys only slightly, particularly with small amounts of carbon present. Brinell hardness numbers were increased about 0.5 by each 0.01 per cent Mn when carbon was present. This rate was lower in the alloys of lower carbon contents. Manganese had very little effect on the ductility of the alloys. The effects of manganese and carbon on the mechanical properties of the alloys were each influenced by the other. The presence of C augmented the influence of Mn and *vice versa.*

Discussion

In the discussion of this splendid paper, Dr. Carl Hering, of Philadelphia, referred to the carbon content of electrolytic iron as deposited. William Blum, of Washington, pointed out that this small amount of carbon was very often mechanically occluded in the deposit coming probably from the anode. However, deposits from oxalate and citrate baths contained more carbon than deposits from sulphate baths. Answering

BIRD'S-EYE VIEW OF MONTREAL

Mr. Rushmore, of the General Electric Co., who questioned the importance and value of electrolytic iron, Dr. Hering quoted Benjamin Franklin: "What's the use of a baby?"

Electrolytic Zinc

John T. Ellsworth, of Park City, Utah, showed some very remarkable photographs illustrating the "Effects of Impurities on the Electrodeposition of Zinc From Sulphate Solutions." When manganese is present in amounts higher than 1 gram per liter, small particles of manganese dioxide remain suspended in the electrolyte and a part of these become imbedded in the zinc deposit. As these particles are saturated with electrolyte, as soon as they are covered with zinc an individual cell is formed; holes develop in the cathode which enlarge with age of the deposit. Iron present as an impurity does not deposit, but uses up current in being alternately oxidized and reduced. About 0.05 gram per liter is the maximum amount permissible. When less than this amount of iron is present, the zinc deposit is particularly smooth and bright.

Copper in excess of 0.02 gram per liter causes the formation of needle-like sprouts; with greater amounts of copper the zinc becomes black and spongy. Cadmium up to certain limits is of distinct advantage. Most of the cadmium deposits with the zinc. However, if more than 0.50 gram of Cd is present, the zinc becomes rough and black. The limiting amount of cobalt is 0.012 gram per liter. The effect seems to be something like both the high manganese and iron. The photographs show large holes in the zinc. The effect of antimony is the most serious. Less than 1 mg. per liter is permissible. In amounts of 2 mg. per liter very distinctive tree-like sprouts are formed, the efficiency is poor and the deposit is soft and spongy and difficult to melt. In the presence of both manganese and antimony, as in the ordinary plant cell solution, the permissible amount of antimony is 0.7 gram per liter.

Walter G. Traub, of the University of Wisconsin, investigated the curious phenomenon brought to the attention of Prof. Charles F. Burgess some time ago. In at-

tempting to gold-plate some articles made of aluminum, Burgess first deposited a coating of zinc, and then covered this with a deposit of gold. After 3 months the gold deposit had entirely disappeared. Mr. Traub took a large number of zinc strips and plated these with various metals. The plated strips were then placed in an electric heater at a temperature of 70 deg. for a period of 2 weeks. The specimens were then examined and it was found that thin plates of copper, brass, gold and silver diffused into the zinc, thus accounting for the disappearance from the surface. The nickel plate, however, did not diffuse into the zinc perceptibly and furthermore a preliminary deposit of nickel would prevent gold, silver and copper from diffusing into the zinc base.

In commenting upon Mr. Traub's interesting results, Harry M. Williams, of Dayton, Ohio, related his experience with copper-plated and brass-plated zinc nameplates. After a very short time the plated metal apparently disappeared. Similarly, Amos G. Reeve, of Oneida Community Research Laboratory, told of the disappearance of gold deposits on tin. R. J. McKay, of the International Nickel Co., advanced the opinion that nickel probably diffused into zinc just as did silver and gold, only there was a difference in the rate of diffusion, the nickel diffusing so much slower. He added that copper diffuses into nickel very rapidly at cherry heat. Replying to William Blum's query as to how much alloying actually took place between deposited metal and base, it was pointed out that in plating tin on iron there was little if any alloying, whereas in the ordinary tinning process by the fire method there was considerable alloying between the tin and the iron. Dr. Fink suggested that it ought to be interesting to compare the diffusion velocity of the various plated metals with the fusion curves of the respective alloys.

De-zincification of Brass

"The De-zincification of Brass" was the title of a short paper by Ralph B. Abrams, of the University of Wisconsin. Experiments are recorded, the results of which indicate that the mechanism of de-zincification appears to be as follows: The first step is the dissolving of the brass as a whole. The copper in solution then redeposits, replacing brass as a unit. This redeposition will not take place unless there is some means of holding the dissolved copper in contact with the brass. This can be accomplished in two ways, one by the presence of a membrane, the other by having a large excess of dissolved copper present. Obviously this latter possibility is a remote one, especially so far as natural conditions are concerned. The membrane may be anything whatsoever, so long as it performs the function of keeping the dissolved copper in contact with the brass. Whether or not de-zincification shall take place can be controlled by merely supplying or taking away the membrane. Briefly, then, the de-zincification of brass is the dissolving of the brass as a whole, the holding of the dissolved copper in contact with the brass by a membrane and the subsequent redeposition of the copper.

Frank S. Weiser, of the Scovill Manufacturing Co., asked the author whether he had found any difference in de-zincification between yellow brass and red brass. Only the yellow brass had been studied. According to Mr. Weiser's experience different brasses and bronzes behave differently. Even in the low bronzes the remaining metal is all copper—no tin is left behind. Mr. McKay, of the International Nickel Co., pointed out that in the case of Monel metal only a mere film of copper is redeposited, protecting the alloy underneath. Answering Henry Howard as to what caused the disintegration of the Monel yacht Seacall, Mr. McKay stated that this was a case of electrolytic action with the salt water as electrolyte; the stem and stern of the yacht and likewise the bolts and rivets were made of iron.

Electrolytic Nickel

The Bureau of Standards at Washington investigated "The Effect of Impurities in Nickel Salts Used for Electrodeposition." The experiments were carried out by M. R. Thompson and C. T. Thomas, and they found that of the impurities likely to be present copper and zinc are especially objectionable. On the basis of their analyses of a large number of commercial salts the following specifications are recommended:

Zinc	not over 0.05 per cent
Copper	not over .02 per cent
Iron	not over .10 per cent
Free acid	not over .10 per cent

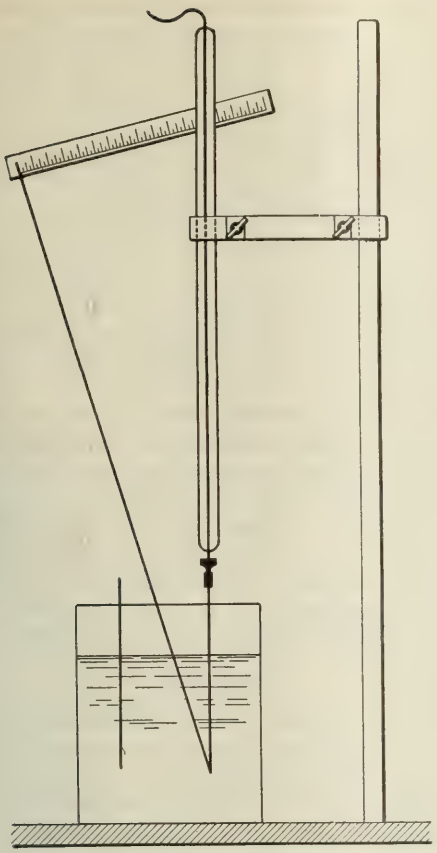
The nickel content is no criterion of the purity of the salts and is useful only in assuring that a definite amount of nickel is obtained. William Blum emphasized the fact that iron was nowhere near as objectionable as zinc and copper. R. J. McKay considered the specifications not stringent enough. In referring to the presence of magnesium in some nickel baths, Prof. Wilder D. Bancroft suggested that this impurity might well be present in the original salt.

Application of the Contractometer to the Study of Nickel Deposition

The last paper of the Thursday morning session was that of Ernest A. Vuilleumier on "The Application of the Contractometer to the Study of Nickel Deposition." The contractometer blade is a piece of sheet platinum, 6x2 cm. by 0.1 mm. thick. A narrow platinum strip is welded to the center of the bottom edge of this foil. This strip is twisted around a thin glass thread serving as pointer. The side of the foil away from the pointer is insulated by painting with vaseline. A millimeter scale, some distance above the cell, is adjusted so that the end of the glass pointer will move freely along its length (see figure). The platinum foil is immersed 3 cm.; the area plated is thereafter 6 sq.cm.

When this platinum foil is made the cathode in a nickel bath and the circuit is closed, the pointer at once begins to move toward the right. When the current is broken the pointer ordinarily stands still at once. After each measurement the nickel is dissolved in warm concentrated nitric acid, the insulation is burned off, and the apparatus is ready for a new contractometric measurement. The degree of contraction decreases when the deposit becomes more coarsely crystalline. Hydrogen, when and while electrolytically deposited, causes the nickel to expand. The contraction of the nickel is evidently a function of the size of the crystalline grains, etc., and the consequent amount of internal stress in the deposit. There are a number of factors influencing the structure of the deposit, such as metal-ion concentration, hydrogen-ion concentration, current density, temperature, etc.

In the discussion of Mr. Vuilleumier's paper William Blum agreed that it was more likely to be the crystal size of the deposit than the occluded hydrogen that de-



CONTRACTOMETER

termines the contraction. What we need now is a reliable method and apparatus to determine the degree of adhesion of electrodeposited metals. Professor Bancroft referred to his experience with platinum black used in contact catalysis. If the black is heated high enough to drive out gases, it will contract very appreciably and thereafter present a much smaller surface. However, if the platinum is precipitated on asbestos and heated, the surface exposed does not change very appreciably—the platinum particles not being in direct contact—and it is easy to obtain good reproducible results in catalytic work. The contraction of porous metals is a big problem and very little is known to date. Mr. Alley, of the Westinghouse company, emphasized the importance of absolute cleanliness in electrodeposition. If this is observed, he mentioned that he had plated rods that could be drawn through a die or forged without any apparent tendency for the deposit to peel. The plated rods were put into a pipe and bent at right angles and back again without any loosening of the deposit discernible. Heating the rods after plating the microscope did not reveal any definite line between deposit and base.

Industrial Heating by Electricity

The entire Thursday afternoon session and the Friday morning session were devoted to a discussion of the principles and practice of industrial heating by electricity. Of particular merit were the papers submitted by the General Electric Co. and the Westinghouse company. In introducing the subject E. F. Collins, of Schenectady, discoursed on "Electric Heat, Its Generation, Propagation and Application to Industrial Processes." The paper is one of the very best ever prepared on this so important subject and was received with much applause. (We expect shortly to reproduce the greater part of Mr. Collins' paper in our columns.) The successful application of electric heat to the varied processes met in the manufacturing world involves not only a knowledge of the particular characteristics, both physical and chemical, of the process involved, but the heating device in question should be of such design as to take account of at least the laws governing the following outlined conditions, tempered with good judgment, resulting from experience:

(1) Chemical laws: (*a*) Chemical reactions at low and high temperatures; (*b*) oxidation, decarbonization at high temperature; (*c*) fluxing of refractories. Effect of furnace atmosphere.

(2) Mechanical laws: (*a*) Expansion and contraction with heat; (*b*) physical strength at low and high temperature; (*c*) crystal growth, with temperature; (*d*) abrasion of refractories when heated; (*e*) mechanical methods of construction.

(3) Physical laws: (*a*) Heat generation; (*b*) conservation; (*c*) transmission; (*d*) absorption; (*e*) distribution; (*f*) storage; (*g*) equalization; (*h*) emissivity; (*i*) potential; (*j*) diffusion; (*k*) quantity; (*l*) temperature gradients; (*m*) control of temperatures through control of heat flow.

(4) Laws of environment and psychology: (*a*) Complete knowledge of the heating process involved; (*b*) more or less complete knowledge of shop methods and individuals who will use the device; (*c*) peculiarities associated with the product to be treated or methods of manufacture should be appreciated; (*d*) What is the frame of mind of the operator? Will he support or antagonize a given design? (*e*) Do executives realize the importance of correct furnace design, and how far will they modify methods to take the fullest advantage of new and progressive equipment offered? (*f*) Does equipment afford better working conditions for the operator?

(5) Economic laws: (*a*) Covering first cost of heating equipment; (*b*) covering operation and operating cost of furnace; (*c*) covering reduction of cost of product and retaining the same quality; (*d*) covering increase in uniformity and quality of product and retaining the same cost; (*e*) greater output for same floor space; (*f*) reduction of labor; (*g*) location of equipment in the line of production, etc.

Discussion

Mr. Collins' paper drew forth considerable discussion. Dwight Miller dwelt at length upon the persistent prejudice against electric heating as against gas heating due to a biased idea of cost of operation and quality of product. The user is apt to lay too much stress upon the relatively higher cost of electric power as against gas or other fuel, overlooking entirely the great improvement in quality and the increase in production. Wirt S. Scott laid stress upon the proper design of apparatus. L. E. Saunders described briefly electrical heating employed by the Norton Co.

F. A. Lidbury, of the Oldbury Electrochemical Co., deplored the lack of sufficient detailed information on the part of the manufacturer of apparatus as to the processes to be carried out in the electric heater or oven. The direct energy cost is not sufficient comparison; we must also take into account the first cost of apparatus and the maintenance cost. Too much importance has been laid by apparatus manufacturers on the efficiency of the apparatus. Often simplicity of design is much more important. For example, there are emulsion heaters sold today that are so illiberally designed that a small increase of temperature of resistor causes breakdown of the apparatus. Frederick J. Ryan, of Philadelphia, said that he had been in the business for twelve years and agreed with Mr. Lidbury that altogether too small attention has been paid to the demands and wants of the consumer. About 90 per cent of the electrical heating apparatus has been turned over to the

user for him to determine whether or not it was properly designed and suitable for his process. The consumer, and not the apparatus manufacturer, deserves the greater part of the credit in the development of electrical heating apparatus. Dwight Miller added that consumer's specifications are usually based on fuel heating practice. The consumer does not always appreciate the uniform heating with electricity as against intermittent heating with fuel. Seldom, too, has the consumer any accurate knowledge as to actual manufacturing costs. Mr. Collins agreed that it was very essential to try out the apparatus and get detailed data before approaching the consumer. Unless you can really show an ultimate economy, it is not fair to go to the consumer.

Principles of High-Temperature Furnace Design

"Principles of High-Temperature Furnace Design" was the title of the next paper, by E. L. Smalley, manager of the Electric Heating Apparatus Co. On the basis of Mr. Smalley's experience the best electric furnaces, judged from the viewpoints of highest quality of products, lowest cost of operation and maintenance and greatest safety in operation at high temperatures, must have these attributes: Muffled type where best suited to the process. Exposed element or radiant form only when best adapted to a process. Elements of sufficient number for cheap renewal. Elements readily and easily renewable. Coils fully supported, and yet free for expansion. Refractory parts thoroughly supported, but free for expansion. No internal connections of coils should be tolerated. Terminal sizes should be larger than the element size. Source of heat must be uniformly distributed. Size of furnace must be governed by the charge. Placement of elements should not control the furnace size. Thermal efficiency should be a controlling feature in decision. Transverse section of heating elements should be round. Exposed elements preferably in corrugated grooves. Elements not chosen to suit a voltage. Total weight of heating element should be high in proportion to the weight of the charge. Efficiency of heat insulation must be adapted to the work to be performed. All of these characteristics, when properly combined with one another, will make the furnace most successful.

Advantages of Industrial Electric Heating

Wirt S. Scott, manager of the industrial heating section of the Westinghouse company, contributed a splendid résumé of the "Advantages of Industrial Electric Heating." He pointed out among other things the following specific points of advantage: (1) With electric heating no products of combustion are produced that might impair the quality of the product. (2) Automatic temperature control. (3) An easier and better temperature distribution, possessing a flexibility of installation and operation not obtainable with any other form of heat. (4) Danger of gas explosions is eliminated. (5) Electric heaters respond quickly when the current is turned on and have a sufficient temperature head to force the heat quickly into the work.

In complimenting Mr. Scott upon his paper President Schluederberg referred to the distinct progress made in industrial heating due to the introduction of the electric apparatus. It is necessary only to see once the large enameling ovens in Detroit to appreciate what wonderful possibilities have been opened by electric heating as compared with fuel heating.

Some Electrical Properties of Alloys at High Temperatures

Another paper of distinct merit was that of Prof. Matthew A. Hunter, director of research of the Driver Harris Co., and his associate, Dr. A. Jones, of Rensselaer Polytechnic Institute, on "Some Electrical Properties of Alloys at High Temperatures." The alloys discussed are those most commonly used in electrical ovens and heating appliances. The specific resistance was determined over the range from room temperature to 1,000 deg. C. The resistance of nickel can be readily raised by the addition of metals which form solid solutions with it—e.g., iron or copper. While the specific resistances and temperature coefficients at room temperature of the nickel-chromium and nickel-chromium-iron alloys have been known for a long time, no exact information on their specific resistances and temperature coefficients at high temperatures has been previously published. With the new data supplied by Messrs. Hunter and Jones, it is possible to calculate the specific resistance of the commercially important materials at any operating temperature. We intend to publish this paper at length in an early issue.

Discussion

In discussing the paper Colin G. Fink referred to the present limiting percentages of chromium in the two types of nichrome wires due to the difficulty of rolling and drawing alloys with higher percentages. As our knowledge of the cause of brittleness is gained, it seems safe to predict that sooner or later we may be able to produce resistance wires with as much as 40 or even 60 per cent of chromium present. The influence of other elements, such as carbon, silicon, etc., although investigated from time to time, is not yet fully appreciated. On the other hand, it was pointed out by Professor Hunter and Frank S. Weiser that nichrome brought into contact with asbestos, mica or other silicates at high temperatures will produce brittleness at the point of contact. E. F. Collins discussed the relative merits of nichrome ribbon as against nichrome wire. He considered the ribbon better for most purposes.

Resistivities of Some Granular Resistor Carbons

Clyde E. Williams, of the Bureau of Mines, and Gordon R. Shuck, professor of electrical engineering, University of Washington, Seattle, reported their determinations of the "Resistivities of Some Granular Resistor Carbons." Granular resistor materials are used in the heating elements of some types of electric furnaces. The important requirements of a satisfactory resistor material are: Small change in resistivity with different temperatures in order to avoid too much regulation of current; a low ash content to obviate too frequent renewing of heating element; high resistance to oxidation; sufficient density, physical strength and hardness to withstand mechanical forces tending to break up particles. Williams and Shuck find that at 1,000 to 1,200 deg. C. the difference in resistivities of the various types and sizes of carbon resistors is not very large. The temperature coefficient of resistivity is negative for all the forms of carbon tested up to 1,000 or 1,200 deg. C., at which temperature it approaches zero and then becomes positive as the temperature increases further. This change was more pronounced in graphite than in the other forms of carbon.

The resistivity increases as the size of the particle decreases. High resistivities are caused by the presence of volatile matter in the resistor material, the resistivity and volatile matter bearing a direct relation for the same material. Ash contained within the particle of carbon increases the contact resistivity and the thermal coefficient somewhat, but the effect is not nearly so large as is that of contained volatile matter. Extraneous ash or foreign matter of high resistivity increases the resistivity and the thermal coefficient to a very marked extent.

The paper was briefly discussed by Dwight Miller, who recounted his experiences with the Baily furnace, the heating element of which is of the granular type.

Heat-Insulation Materials for Electric Heating Apparatus

A subject of fundamental importance is the proper selection and application of "Heat-Insulating Materials for Electric Heating Apparatus." J. C. Woodson, of the Westinghouse company, has studied this subject for many years and presented to the meeting a detailed report, including numerous curves and photographs. Although the insulation materials available for low temperatures are more or less numerous, there are few satisfactory products on the market today for high temperatures.

Discussing Mr. Woodson's paper, Carl Hering, of Philadelphia, mentioned his experience of whitewashing the outside of his furnace and thus very perceptibly improving the heat insulation. Upon compressing a porous insulating material, the heat flow through the material at first decreases, but upon further compression the heat insulation value drops off rapidly. Dr. Hering strongly recommended the use of the thermal ohm, as it saves a good deal of calculation. Prof. Alfred Stansfield of McGill University emphasized the importance of avoiding too thick a layer of outside insulating materials, such as Sil-o-cel, especially in high-temperature furnaces. The melting point of Sil-o-cel and similar materials is comparatively low and if all the heat is trapped, it soon accumulates in the inner layers, a temperature approaching that of the bath is attained and the Sil-o-cel melts. Similarly it does not pay to make the roof of the electric steel furnace too thick. Frank W. Brooke, of the Electric Furnace Construction Co., mentioned the case of using 4½-in. Sil-o-cel as outside insulation which started to fuse after ten heats. Replying to Henry Howard of the Graselli company as to the advantages of using air spaces at definite intervals between the layers of brick or asbestos, Mr. Woodson said that above 300 deg. C. air spaces are of no advantage on account of the convection currents. There undoubtedly would be some advantage were these spaces evacuated.

Firing of Ceramics in Electric Furnaces

E. L. Smalley discussed the "Firing of Ceramics in Electric Furnaces." The cleanliness of atmosphere, the uniformity of temperature control and the ease of duplication of temperatures have made the electric furnace very adaptable to the china and glass industries. L. E. Saunders, of the Norton Co., pointed out that a commercial process for the electric firing of grinding wheels has not yet been worked out. Organic binders for these wheels require but 100 to 200 deg. C. and wheels with the sodium silicate binder are not heated above 250 deg. C. Professor Bancroft considered a small high-temperature electric furnace for porcelain firing a very desirable and welcome piece of apparatus. Artists could then fire their own china and thus we would encourage the development of artistic decorative china. The art would no doubt develop to heights never attained before. Frank W. Brooke and F. A. J. FitzGerald agreed that there are wonderful possibilities along this line of porcelain firing, but who is to pay for the development of such a small electric firing furnace especially designed for artists' use?

Other Papers

With the aid of an interesting set of slides Frank W. Brooke described in detail "Methods of Economically Handling Materials in Electric Furnaces." In some instances the work was carried through the furnaces on cars, in others the work was attached to an endless chain, and in all cases provisions were made to conserve as much of the heat as possible.

Wirt S. Scott gave a detailed account of the "Development of Industrial Electric Heating for Low-Temperature Enameling" and described the enameling ovens used in the automotive and typewriter industries.

The concluding paper of the symposium on industrial heating was presented by C. B. Gibson, of Pittsburgh, on the "Electric Annealing of Malleable Iron." Very little has been done along this line and developments are very much in the experimental stage. There are many advantages of electric annealing as against annealing in fuel-fired furnaces. Among others there is the elimination the packing pots, stacks, flues, stokers, etc., and considerable saving in labor.

Simple Electric Crucible Furnace for Melting Aluminum

The final paper of the Friday morning session was a short report on the construction and operation of an electric crucible furnace, by Prof. A. Glynne Lobley, director of the electrochemical laboratories, Victoria University of Manchester. The crucible, which will hold 40 kg. of aluminum, is heated by means of a resistor of nichrome ribbon 6.3 mm. wide and 1 mm. thick. An aluminum alloy containing 8 per cent of copper was melted in the crucible, and in an average week 465 lb. was melted with an energy consumption of 363 kw.-hr. The voltage across terminals was 200. Full details of construction were given.

Electric Steam Generators

P. S. Gregory, of the Shawinigan Water & Power Co., described the improved type of electric steam generator developed by F. T. Kaelin, chief engineer of the company. The water-resistance electric steam generator consists essentially of a closed pressure vessel to which is connected a source of water supply and from which water may be drawn off at the bottom and steam at the top. In this vessel electric energy is made to flow through the water from an electrode in the form of a plate or tube, to the shell of the vessel, or to the metallic inner lining. Alternating current energy is used at a pressure varying from 110 up to 12,000 volts. The generators are constructed for the use of three-phase power, either by employing three electrodes in one vessel or by the use of three vessels with one electrode in each, in which case the outer shells are connected together in star. In this type of generator there is no

heating surface, the generation of steam taking place throughout the water, and as a consequence no portion of the apparatus is at a higher temperature than the temperature of the steam. This is a most important feature from the viewpoint of safety and continuity of operation, as can be readily appreciated.

The chief advantages of the water-resistance type of steam generator over the metallic resistance type are freedom from electrical and mechanical troubles, ease of regulation and cheapness.

There are in operation in Canada and in the United States at the present time installations of electric steam generators totaling about 150,000 kw., which are for the most part installed in paper plants.

DISCUSSION

Mr. Gregory's paper drew forth a long, animated discussion. F. A. Lidbury, of Niagara Falls, who has had considerable experience with the electric steam generators, commented upon the importance of studying the conditions and requirements of each individul mill or plant. The rising coal prices have done much in popularizing electric steam. Dwight Miller referred to successful installations in various paper mills. Eric A. Lof, recently returned from a trip to Sweden, reported that hundreds of electric steam boilers are in daily use in Europe, largely operated on surplus power. Why not do away with many of the coal-fired steam boilers in this country and introduce the electric steam accumulators? In Europe there are forty-two successful installations of that kind. Dr. Carl Hering inquired whether any appreciable decomposition of the water were discernable, due to electrolysis. Philip H. Falter, of the Canadian Electro Products Co., replied that very little is known regarding any electrolytic effects, but it has been observed that electrodes wear out entirely out of proportion to the energy consumed. Furthermore, with twenty-five-cycle current there is greater electrode wear than at sixty cycles. Mr. Lof cited a Swiss case where very low cycle current was used and dissociation of the water took place. Others who participated in the discussion were Duncan MacRae, of the Westinghouse company, Acheson Smith, of the Acheson Graphite Co., and Wilder D. Bancroft, of Cornell University.

A New Induction Furnace

J. Murray Weed, of the General Electric Co., gave a detailed account of a new induction furnace. In this furnace, as in other induction furnaces, the heat is produced by an electric current induced by transformer action in a looped portion of the molten charge, which we will call the secondary. This secondary is distinct from the melting chamber pot, in which the cold charge is received, melted and held for refining and pouring. The success of the furnace depends upon a continuous, automatic circulation of the molten metal between the secondary and the melting pot, to prevent overheating in the former and to deliver the heat to the cold metal in the latter. It is in the form of the secondary, and in the character of the circulation and the method of producing it, that the new fundamental features of this furnace are found.

The circulation in this furnace is effected by the force of electromagnetic repulsion, set up through the medium of the magnetic leakage field, which exists between primary and secondary in any transformer. This force is proportional to the square of the current flowing, and is familiar to all transformer engineers as having caused much trouble in the wrecking of transformers when the windings were not held with sufficient rigidity to withstand the enormous forces of this nature which are set up when short circuits occur.

The induction furnace is, in fact, a special case of a short-circuited transformer, in which the internal impedance is comparable with the total full load impedance of the secondary circuit of the ordinary transformer. The repulsive force in this furnace, therefore, is not excessive, as in ordinary transformers when short-circuited, but only such as exists in ordinary transformers when normally loaded.

DISCUSSION

Oscar Brophy, of the Ajax Metal Co., referring to the circulation of metal in the Weed furnace, said that the method of producing this circulation is not new, because it was described by him in the U. S. Patent 1,296,752 granted March 11, 1919. He felt that the flow of metal in the Weed furnace depended upon two facts: (1) There is an electrodynamic force of repulsion between the primary and secondary as their currents are in opposite directions. (2) This force is given an axial direction, so as to cause the metal to flow up into the bath, by means of the axial displacement of the primary. Dr. Hering likewise felt that there was no new principle involved in the furnace described by Weed. John A. Seede, associated with Mr. Weed, considered the furnace a radical departure. Mr. Weed added that the furnace is still in the experimental stage.

Carbon Bisulphide

George A. Richter, of the research laboratories of the Brown company, has carried out a detailed investigation of the electrical production of carbon bisulphide. We expect to publish this paper shortly in full.

Preparation of Perchlorates by Heating Chlorates

Frank C. Mathers and J. W. H. Aldred carried out experiments seeking to increase the yield of perchlorate by heating chlorates. But no variation in the conditions of heating chlorates and no catalysts were found whereby the yield could be increased. A maximum yield of about 55 per cent perchlorate was obtained by heating 1 to 50 grams potassium chlorate for 30 to 60 minutes at 480 to 540 deg. C. Most substances, when added, decreased the yield. The sodium chlorate gave a smaller yield. There seems no possibility that the chemical preparation of perchlorate from chlorate can equal the electrolytic method.

Electrosmosis and Electrophoresis

Oliver C. Ralston, in his paper, proposed the terms "electrosmosis," "electrophoresis," "cathodophoresis" and "anodophoresis" (1) to replace a large number of other words, some of which are incorrectly used and all of which are awkward; (2) to gain uniformity of nomenclature in conformity with the two words "electrolysis" and "electrostenolysis," and (3) to provide single descriptive nouns, which when properly modified can be used as verbs, adjectives or participles that easily displace present clumsy phrases.

Electrolytic Oxidation of Isoeugenol

Prof. Alexander Lowy, of the University of Pittsburgh, is an ardent enthusiast for the electrolytic preparation of organic chemicals, and at the Montreal

leeting he reported upon one of his latest researches, iat on isoeugenol, which he had carried out jointly ith Miss C. M. Moore. The first part of the investigaion here reported dealt with the method for the prepiration of vanillin as described in the German patent .R.P. 92,007. It was found that the specifications of he patent are not exact, in spite of statements to the ontrary appearing in many textbooks. Repeated tests ave rise to no appreciable amounts of vanillin—a esinous substance being obtained instead. Perhaps erivations of isoeugenol, such as the acetyl or benzoyl, ould be used to produce the desired results. Further nvestigation is desirable.

Insulating Compounds

The two concluding papers of the Friday afternoon ession dealt with insulating compounds. The first of hese was by Dr. H. C. P. Weber, of the Westinghouse ompany, on the "Changes in the Electrical Conducivity of Varnishes During Drying" and the second by Dr. C. J. Rodman on "Arc Action on Some Liquid Insulating Compounds." Both subjects are of great importance. There are many intricate problems presented in the study of insulating compounds and it akes the closest co-operation of chemist and electrical engineer to hasten a solution of these problems.

Social Features

So much had been planned by the local committee in social entertainments that it was difficult to find time to take in even a small fraction of these. Thursday evening was spent at McGill University and the members had the pleasure of listening to a scholarly discourse on "The New Philosophy of Physics" by Dr. A. S. Eve, a physicist of world-wide repute. The experiments were exceptionally well planned and carried out. Golf enthusiasts spent a number of delightful hours at the Kanawaki and Royal Montreal Golf Clubs. All of the outings arranged for the ladies were carried through to perfection under the able and clever guidance of Mrs. C. R. Hazen. There were automobile and coach sightseeing tours; a very sumptuous tea on the lawns of the Royal St. Lawrence Yacht Club; an equally enjoyable gathering at the Engineers' Club; a theatre party; and finally the ladies joined in the excursion to Shawinigan Falls.

Shawinigan Falls

An exceptionally attractive and enjoyable feature in the program was the all-day outing to Shawinigan Falls. Special coaches reserved for the society were attached to the midnight train, arriving at the Falls early Saturday morning. The local members, under the most able leadership of R. A. Witherspoon, gave the visitors a cordial reception. Automobiles were in readiness to take the party to various plants of interest. At the Shawinigan Water & Power Co.'s plant opportunity was afforded to inspect a new horizontal unit in the process of installation. As F. T. Kaelin had pointed out, Shawinigan Falls is an ideal place for water-power development and the manufacture of electrochemical products. Not only is there an available high head and a large quantity of water with fairly constant flow, but the St. Maurice River widens into a lake just above the falls, and after making a sharp bend forms a second lake 145 ft. below. This brings the upper and lower water levels within a short distance of each other, thus

POWER DEVELOPMENT AT SHAWINIGAN FALLS

providing an extremely economical location for the power plant at the bottom of the slope between them. Part of the power used at the Falls for the manufacture of carbide, carborundum, aluminum, electrodes, acetic acid, paper and other products; a large portion of the power is transmitted to Montreal.

Canada Carbide Co.

At the Canada Caribe Co.'s plant the visiting electrochemists saw the large 6,000-kw. carbide furnaces in operation. These furnaces are about 10 ft. high with a base about 10x10. The two electrodes are 48 in. wide, 16 in. thick and about 7 ft. high. They are built up of three electrodes each, 16x16 in. square, the seams being carefully luted. The voltage of the carbide furnaces is kept constant at 125 to 130 volts and the amperage is about 30,000 per phase. The electrodes have a life of about 10 to 12 days, operating 24 hours a day. The feed consists of two parts of limestone to one of coke; the carbide is tapped at intervals, the tapping temperature being about 1,000 deg. C.

Belgo Paper Co.

At the Belgo Paper Co.'s mill one of the novel features was a 25,000-kw. electric steam generator. There are three iron cylindrical units, star-connected and operating at 6,600 volts. An iron cylinder next to the shell forms the one electrode and a cast-iron perforated pot about 18 in. in diameter and 16 in. high is concentrically suspended and forms the second electrode. Kaelin electric steam generators are also installed at the Laurentide Pulp & Paper Co.'s mills. These have a maximum capacity of 70,000 kw., or 7,000 boiler horse-power.

A complimentary buffet luncheon was served on the lawn of the inn. This luncheon was the outstanding social event of the meeting. How much it was enjoyed and appreciated by the members and guests is difficult to realize. A most generous and entertaining host, with a capacity for efficiency seldom equaled saw to it that a delicious and spirited luncheon was served with remarkable dispatch and comfort to all. The good humor and cordiality of hosts and guests alike, made for an abundance of good will and happiness. Robert Turnbull, A. T. Hinckley, Howard C. Parmelee and R. A. Witherspoon took turns as song leaders, introducing new verses and variations in many of the electrothermic ballads and electrocomical ditties so familiar to all members of the society. This closing event of the Montreal convention seemed more like a happy family reunion than a staid convention of learned men. The members returned in a body to Montreal, and soon after all were on their way home.

Electrolytic Iron From Sulphide Ores

Iron of Extraordinary Purity Is Made From Pyrite, Recovering Sulphur as a Byproduct—Costs Will Be Low Enough Not to Handicap Wide Use of the Metal

AN ESTIMATION of the commercial possibilities of electrolytic iron in America was given by F. A. Eustis in a paper read Sept. 27 before the Mining and Metallurgical Society of America. He recounted briefly the various laboratory investigations which have been published during the last 50 years, and described the experiments he and his associate Charles P. Perin have been making.

Commercial Operations in France

Their interest was revived by the use of electrodeposition to build up worn steel parts[1] (a process adopted by the allied armies) and the undoubted commercial success of the Société le Fer at Grenoble and two or three other localities in France.[2] Founders of the latter enterprise took out their first patents in 1910. As is perhaps well known, their product is iron boiler tubing, deposited on a rotating cathode, 4 m. long. Soluble cast-iron cathodes are used, the current density is in the neighborhood of 100 amp. per sq.ft., led in through the rotating mechanism. Their tanks are located somewhat above the floor; electrolyte is distributed through an overhead pipe and rubber hose connections. It overflows to a sump, from which it is pumped to a tank containg iron turnings. This performs a double purpose: it keeps the solution both reduced and filtered. Air is blown into the electrolyte to absorb hydrogen—as deposited the iron is somewhat brittle from hydrogen, but a gentle annealing drives off the gas and renders the metal extremely ductile. A high speed of rotation of the cathode was thought to be very important—it was maintained at a correct rate by observing a pilot electrode consisting of a cone rotating at known speed.

The Grenoble plant produces about 1½ tons of boiler tubes per day, ready for the market after stripping from the cathode, cutting to length and slight annealing. Variation in gage amounts to no more than 0.002 in., plus or minus. The iron is very pure; it is quite soft so that it is easily expanded into its connections. Its superior thermal conductivity increases the efficiency of the boiler, and its resistance to corrosion enables it to resist the pitting action of many waters.

Some Iron Is Made in Illinois

Only one American firm is now making electrolytic iron in commercial quantities: the Western Electric Co. has a plant at Hawthorn, Ill., producing about 2 tons per day.[3] Its tank house looks much like a copper refinery. Brittleness of the deposit is here a virtue; the iron is knocked off the polished steel cathode, ground in a ball mill and tumbled with zinc dust (thus coating each particle). The powder is then compressed and made into cores for loading coils for telephone installations, for which it has been found to be peculiarly advantageous.

In experimenting with some complex Cuban iron ores[4], Perin and the author decided to use SO_2 from pyrite as a reducing agent for their chloride solutions, but it was found that the pyrite residue contained as much iron as was recovered from the process. Consequently it seemed logical to use a sulphide ore not only as a reducer but also as an ore. As a matter of fact, pyrrhotite (the monosulphide of iron) dissolves easily in ferric chloride, giving an astonishingly complete reduction:

$$2FeCl_3 + FeS = 3FeCl_2 + S.$$

This reaction is exothermic, producing about 700 B.t.u. per lb. of iron dissolved—an important advantage, since successful electrolysis appears to demand hot solutions.

Ground pyrite (FeS_2) is not as good a reducer as pyrrhotite, only 60 per cent of the metal going into solution before the residue is insulated by a sulphur deposit. Pyrite may be easily changed to pyrrhotite by a reducing roast; flowers of sulphur or brimstone is a byproduct of more value (at present market prices) than the cost of the operation. In view of the tremendous amount of nearly pure iron sulphide (one Spanish mine alone has 100,000,000 tons developed) to say nothing of the vast tonnages of complex sulphides carrying attractive amounts of gold and silver, it appears to Mr. Eustis that the most of our future electrolytic iron will come from these sources, and this idea forms the basis of his patented processes.

Purification of Electrolyte

The process, as is now in operation in their experimental mill at Milford, Conn., consists of grinding the sulphide and agitating the pulp with spent electrolyte (containing $FeCl_3$ and $FeCl_2$ in equal molecular proportions). Sulphur and other insolubles are filtered.

Any copper in the ore goes into solution, but it is precipitated very cleanly and easily on metallic iron. (In passing it may be remarked that this may prove to be a more economical process for the recovery of copper from lean pyritic ores than the present methods of selective concentration and smelting, wasting all the iron, either in a mill tailing or in a blast-furnace slag.) Zinc and cadmium may be taken out of solution as a sulphide, precipitated either by H_2S or a soluble alkaline sulphide. (After about 9 months' experimentation, the Consolidated Mining & Smelting Co. at Trail, B.C., has been able to make iron sheets of most excellent quality, and containing 0.04 Zn, from a zincy pyrrhotite tailing.) Other impurities are not expected to give much trouble, since we have learned how to make solutions of extraordinary purity in our struggles with electrolytic zinc. Iron solutions do not appear to require such extreme purity. Furthermore, iron sulphide is so widespread that if one ore gives trouble, another could usually be substituted. In large-scale work, the operator would doubtless bleed a moderate amount of solution from the circuit in order to keep certain accumulating impurities within bounds. This would involve a loss of its chlorine,

but it would probably be replaced with gas made on the spot, given cheap power and salt.

Details of Deposition

The diaphragm cell used is much like a caustic soda cell. It contains graphite anodes. As iron is deposited from $FeCl_2$ in the cathode compartment, the chloride migrates through the diaphragm to the anode and oxidizes two molecules of ferrous chloride. The solution in this compartment is circulated so that it never reaches a greater concentration than 70 grams per liter of $FeCl_3$ (and about the same of $FeCl_2$). This prevents free chlorine from giving trouble in the solutions and atmosphere, and from lowering the electrical efficiency.

When conditions are right, iron is deposited at high current efficiency, exceeding 95 per cent. That is to say, 1 gram of iron may be had per ampere-hour. The amount per kilowatt-hour depends of course on the resistance of the cell, which in turn depends upon the composition and temperature of the electrolyte, but most especially on the current density. For instance, other conditions being equal, a current density of 20 amperes per square foot requires 1 volt, 40 amperes 2 volts, and 160 amperes 4 volts. Therefore if a plant can operate 90 per cent of the time, and power costs $20 per kilowatt-year (a figure at which large blocks have been offered), one ton of iron can be produced for $2.40 worth of current at 1 volt, $4.90 at 2 volts and $9.80 at 4 volts. Part of the saving in power when operating at low voltages would be offset by higher overhead charges on account of the more extensive plant needed. Power costs of not more than $5 per ton compare favorably with the cost of coke for blast-furnace iron.

Many difficulties must be met before ferric chloride solutions can be handled in large volume. Most of the equipment at Grenoble was made of wood, it being quite resistant and easy to change. They are now rebuilding permanently in concrete—probably of a special nature. Sulphur resists hot $FeCl_3$ very well indeed, and it will doubtless be used to a great extent, either pure or as a cement for silica sand. Pumps may be located in the reduced portion of the cycle. Stoneware pumps will doubtless give very good results—rubber-lined pumps also have possibilities.

Commercial Possibilities

Physical properties of the deposited iron have been summarized by Bradley Stoughton[5]. Its purity, ductility, rust-resisting properties and high thermal and electrical conductivity fit it for a number of special uses, to which it will be welcomed and which will furnish the early market. Thin boiler tubes, fine iron wire, deep stamping stock, cold-worked parts of precise shape and electrical or magnetic specialties are attractive possibilities. Such uses might easily absorb ¼ million tons of iron a year. A similar or even greater tonnage will undoubtedly be absorbed by the manufacturers of crucible and superfine electric steels for tools and high-strength alloys, if the cost could be kept somewhat below that of Swedish iron, or the price of selected scrap plus the necessary refining costs.

Estimates of Costs

All these possibilities depend upon the cost of the iron. Certainly the ore will not be a limiting factor. As indicated above, there is a great wealth of pyrrhotite available, which can be had, ground, for $5 or $6 per ton. These ores are of such a nature that no costly difficulties from impure solutions need be expected. At present market prices, the sulphur recovered is worth more than the ore will cost, so for the time being the raw iron will be free. Of course a great tonnage of electrolytic iron from this source will glut the sulphur market. (The United States' annual consumption is now not more than 1,500,000 tons of sulphur, which would be produced as a byproduct from 3,000,000 tons of iron. New uses of sulphur may be found, but any important tonnage, such as for concrete, could carry only a very low price.)

Labor and supplies are quite high in plants now operating. This is due in great measure to the small scale of the operations and the semi-experimental nature of the work. As a matter of fact, Mr. Eustis sees no factor which would demand permanently high costs for labor and supplies. The electrolytes must be kept hot, but careful calculations show that this is a problem of insulation, since both the reducing and the deposition reactions generate quite large amounts of heat.

Electric power in this country from water or coal is unlimited, its development only awaiting a market. Certainly the cost for electricity will always compare favorably with the fuel cost in a blast furnace. Operating voltages are very low, and all the electrical details for an electrolytic refinery have long since been worked out.

Capital cost may be balanced against the power cost. An expensive large plant may operate on little power at low voltage, or a smaller plant can get the same output with greater power. Mr. Eustis thinks, however, that capital charges may fall within $8 to $12 per ton of iron produced.

In closing, the speaker gave the opinion that the possibilities of the process are great, although the road ahead is far from easy.

Corrosion of Rifles

A source of great loss, not only to the national defenses but to every owner of a firearm, is the slow corrosion which gradually destroys the accuracy of fire, even when every effort is made to protect the rifling by cleaning the barrel and keeping it well oiled. This "after-corrosion" under an oil film has been studied by the Bureau of Mines. The experiments were performed on the U. S. Infantry rifles and ammunition, using the high-pressure smokeless cartridge primed with typical fulminate, sulphocyanide and sulphur compositions.

Smokeless powder leaves behind no nitrocellulose residue (except when the pressure developed is relatively low, as in firing blank cartridges), nor does it leave a corrosive acid residue. After-corrosion in this instance is due to a water-soluble salt (KCl) from the decomposition of the chlorate in the primer. This salt is retained in pits or minute chatter marks in the bore, from which it cannot be removed by wiping. However, the salts easily dissolve in water, even condensing it from the atmosphere below the dew point, and corrosion proceeds by reaction with atmospheric oxygen. The trouble will disappear when a primer containing no chlorate may be developed.

Meantime, after-corrosion may be suppressed by washing in naphtha and then in hot water, carefully drying, oiling and then keeping both ends of the bore tightly corked. Many non-aqueous compositions recommended for cleaning firearms possess little or no value.

The Air Bleaching of Nitric Acid*

An Experimental Study of the Bleaching of Nitric Acid With Air—Effect of Temperature, Air Velocity, Etc., Discussed and Analyzed—A Formula Is Derived for Calculating the Bleaching Coefficient Which Is Checked by Experiment

By W. G. Whitman† and Laighton Evans
School of Chemical Engineering Practice, Massachusetts Institute of Technology

THE problem of bleaching nitric acid to be used in the manufacture of mixed acid has assumed greater importance as the specifications on lower oxide content have become more rigid. This has stimulated the development of better methods of operating and controlling the bleaching process which is necessary in the older types of plants. This paper presents the results of experimental work on bleaching nitric acid at varying temperatures and air rates, and develops a theory and an equation whereby these results can be applied to industrial practice.

Removal of Lower Oxides. The process of bleaching strong nitric acid with air consists essentially of volatilizing the lower oxides present and removing them by the current of air. There are, therefore, three important factors involved. In the first place, the vapor pressure of the lower oxides, determined by their concentration and the temperature of the solution, is a direct measure of their tendency to volatilize. Next, a source of heat is necessary to supply the heat of vaporization. Finally, the volatilized oxides must be removed from the system—a process which is effected in this case by a current of air. These three factors will be discussed separately.

First Factor: Vapor Pressure of Lower Oxides. Owing to the relatively low concentration, the vapor pressure of the lower oxides at any given temperature may be assumed to be directly proportional to their concentration in the solution (Henry's Law)—i.e., $p = \alpha N$ where p = the partial pressure of lower oxides, N = the concentration of lower oxides in the solution (expressed as per cent N_2O_3) and α = the proportionality constant. It is obvious that α will vary with the temperature of the solution, and, by analogy with other cases, an exponential function may be predicted.

Second Factor: Heat of Volatilization. The major source of heat is the solution itself, which cools during the bleaching process. It is, of course, possible to supply heat externally and prevent cooling, but this does not alter the concept. It is impracticable to supply much heat in the air used for bleaching, since the sensible heat of the air stream is necessarily small compared to the total heat required for evaporation.

Third Factor: Mechanical Removal of Vaporized Oxides. The air used to remove the volatilized products could theoretically become saturated in an ideal bleaching pot. Actually, this condition is nearly realized, so that an approximation that the air reaches the same percentage saturation under different conditions of temperature and velocity is justified. The oxide removal should, therefore, be nearly proportional to the air rate, varying only by slight differences in the saturation of lower oxides at different air velocities.

The bleaching formula derived from these considerations is as follows:

$$-\frac{dN}{d\theta} = \beta N$$

Where N = per cent N_2O_3 in solution
θ = time in minutes
β = the bleaching coefficient, defined as the drop in per cent lower oxides per minute in a 1 per cent solution.

$-\frac{dN}{d\theta}$ = the instantaneous rate of bleaching.

The above equation states that the rate of removal of the lower oxides is a function of the amount of oxides present. This equation integrates to the form

$$\log_e N = -\beta\theta + \text{constant}$$

or, between the limits of an initial concentration N_1 and a final concentration N_2

$$\log_e \frac{N_2}{N_1} = -\beta(\theta_2 - \theta_1)$$

The coefficient β is not a constant, but varies with the temperature of the solution and the air rate, and should be nearly proportional to the latter. All laboratory runs were made with constant temperature and air rate, so that β was itself constant for any one run. It is obvious that the validity of the theory and assumptions given above must be demonstrated by comparing the equation to actual data obtained in bleaching runs.

The absence of data on the vapor pressure of lower oxides has made it impossible previously to calculate the rate of bleaching. In this work it has been considered that the actual vapor pressure obtained from laboratory bleaching runs is the vapor pressure of oxides above the solution. This is not strictly true, since, as noted previously, the air does not become saturated. However, the approximation that the same degree of saturation is reached in all cases permits this assumption and, furthermore, such vapor pressure data are applicable to other bleaching runs in which complete saturation is again unattainable.

Loss of Nitric Acid. During the removal of lower oxides, nitric acid will itself be volatilized, but the problem is somewhat simplified in that the vapor pressure of nitric acid remains constant during a run at any one temperature, since the amount vaporized is so small. Although data on the vapor pressures of HNO_3 in concentrated solutions at higher temperatures are a little uncertain, it is possible to calculate the values from data at lower temperatures using the Clapeyron equation. These values may be compared with observed values.

The experimental work consisted in bleaching nitric acid on a laboratory scale under various conditions of temperature and air rate. Compressed air was passed through a calibrated flow meter and then to a 2-liter bleaching flask, where it was distributed in the acid by

*Paper presented at the meeting of the American Institute of Chemical Engineers, Niagara Falls, N. Y., June 19, 1922.
†Assistant Professor Chemical Engineering Practice, Massachusetts Institute of Technology

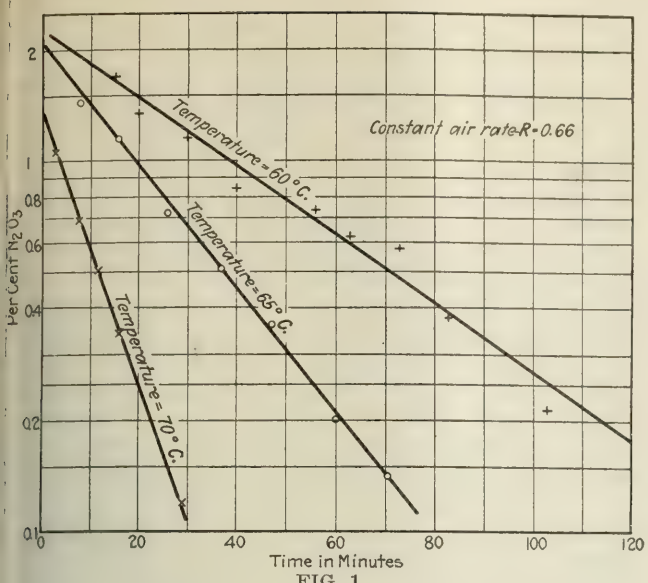

FIG. 1

a perforated glass coil. The flask was equipped with a thermometer, a gas burner for heating and an exhaust tube for the gases, which also acted as an air-cooled condenser. The amount of nitric acid lost during the process by evaporation was measured by collecting the condensate.

Each test consisted of bleaching 1.5 liters of raw acid (93 per cent HNO_3) at a definite temperature and air rate. At intervals during the bleach acid samples were siphoned from the flask and analyzed for dissolved lower oxides of nitrogen by titrating a diluted sample with tenth normal $KMnO_4$; the oxides being expressed as N_2O_3. Approximately 200 c.c. of the acid was removed as samples, giving an average volume of 1.4 liters.

The first set of three runs was made at constant air rate, equal to 0.66 liter air per minute per liter of acid, and temperatures of 60, 65 and 70 deg. C. respectively. Air rate is expressed as the ratio of air volume per minute per unit volume of acid, so that the results would be comparable with plant practice. The second set of three runs was made at constant temperature—namely, 70 deg. C., and air rates of 0.51, 0.66 and 0.75 liter per minute per liter of HNO_3 respectively.

If the original equation $\log_e N = -\beta\theta +$ constant is true, then ploting $\log_e N$ against β should give a straight line whose slope equals $-\beta$.

Fig. 1 shows log of the lower oxide concentration plotted against the time of bleaching for runs at three different temperatures, but at a constant air rate. The points for a given run all fall close to a straight line,

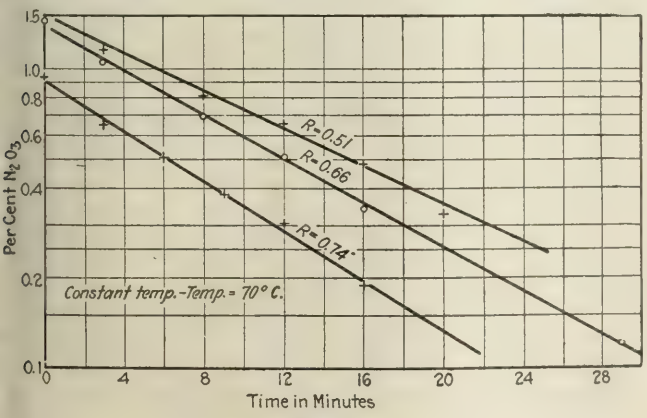

FIG. 2

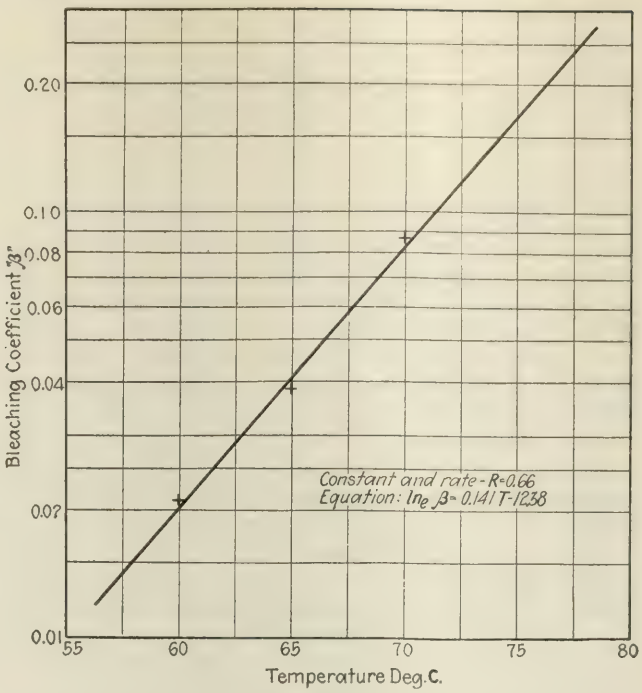

FIG. 3

thus verifying the original law for rate of bleaching. Fig. 2 shows the log of the lower oxide concentration also plotted against time of bleaching for runs at three different air rates, but at a constant temperature. These points for a given run, all falling close to a straight line, again verify the original equation.

The slope of each line on Figs. 1 and 2 equal the bleaching coefficient, $-\beta$, for that specific temperature and air rate, as seen from the equation above.

The variation of β with temperature at constant air rate, Fig. 3, is represented by an exponential function as predicted, since the vapor pressure vs. temperature relation in general is exponential. An inspection of Fig. 3 shows that the log of β when plotted against temperature gives a straight line and that the rate of bleaching doubles every 5 deg. C. The equation showing the value of β with variation in temperatures is $\log_e \beta = 0.141\ T - 12.38$.

The rate of bleaching is nearly proportional to the amount of air used, Fig. 4, the line failing to pass through zero due to incomplete saturation of the air at the velocities in question. The equation showing the variation of β with air rate is $\beta = 0.0122 + 0.112\,R$. Fig. 5, showing the combined effect of temperature and air rate on the rate of bleaching, is self-explanatory.

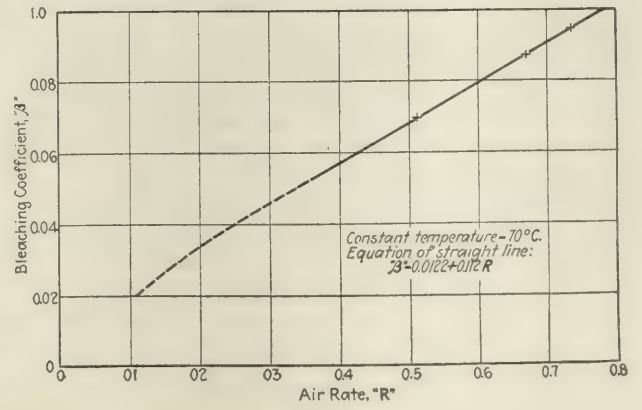

FIG. 4

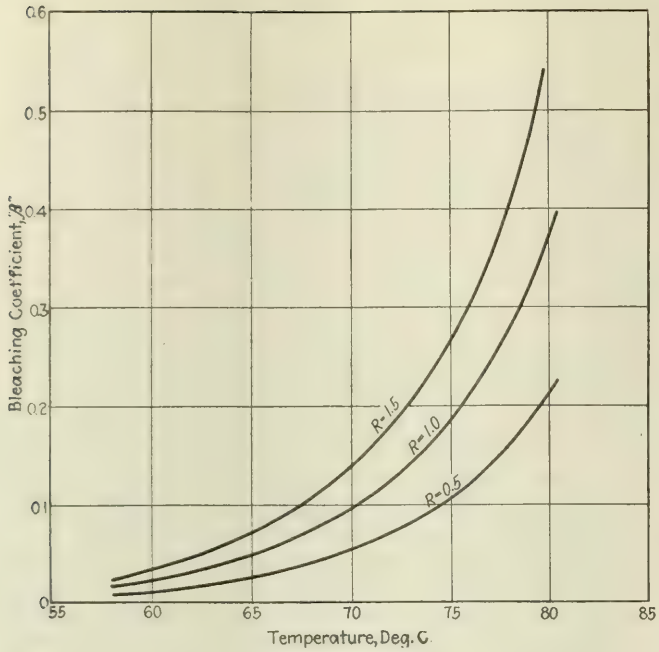

FIG. 5

Fig. 6 shows vapor pressures of nitric acid and lower oxides above 93 per cent nitric where the lower oxide concentration is 1 per cent. The values calculated by extrapolating data[1] by means of the Clapeyron equation and those experimentally determined points are compared with data by Pascal[2] and Creighton and Githens.[3] The lower oxide vapor pressures are admittedly low, due to incomplete saturation of the air, as already noted. This plot shows the lower oxide pressure for a 1 per cent solution, and Henry's law may be used to calculate the pressure above a solution of any other concentration.

These results indicate the advantages to be gained by using a high temperature. An inspection of the integrated equation, $\log_e \frac{N_1}{N_2} = \beta(\theta_2 - \theta_1)$, shows that bleaching between any two concentrations N_1 and N_2 requires a time inversely proportional to β, the bleaching coefficient. Since β doubles with a 5 deg. C. rise in temperature, bleaching time at 40 deg. C. therefore would be sixty-four times as long as at 70 deg. C. The effect of air rate may be simplified to the statement that bleaching time is inversely proportional to the air rate employed.

In plant bleaching, the temperature of the acid drops during the process due to evaporation of lower oxides and nitric acid. This fact must be allowed for in applying the constants obtained from laboratory runs. For example, a laboratory bleaching from 0.26 to 0.06 per cent at 70 deg. C. and 0.66 R would require 18 minutes, while a plant bleach with the same air rate, starting at the same temperature but finishing at 64 deg. C. would take 32 minutes. For accurate calculation of a plant run, it is necessary to obtain temperatures during the bleaching period, look up the corresponding values of β, plot these against the time, and get an average β from the area under the curve. The application of this method gave checks on the lower oxide removal of better than 10 per cent in all cases. The value of β to be used for this plant run was found at 66 deg. C.—i.e., two-thirds of the difference between 70 and 64 deg. C. subtracted from the higher temperature. This latter rule gives a fairly close approximation in all cases, so that it is unnecessary to use the accurate method mentioned above. Thus, in bleaching an acid high in lower oxides dropping from 70 to 55 deg. C., the average value of β would be 60 deg. C.

Bleaching may be effected by merely heating the acid providing the vapors have opportunity to escape from the system. It is possible to raise the acid to such a temperature that the lower oxides boil off, the boiling point rising as the oxide content decreases. Some work has been done along this line with the object of determining the optimum combination of heating and air blowing to give the desired bleaching, having in mind the loss of nitric acid, the heat requirements and the time necessary. The results of this work will be published at a later date.

The loss of nitric acid incurred in bleaching has been calculated from the vapor pressure data shown by the line on Fig. 6. While the results are not strictly quantitative, it can be stated that, in bleaching to a fixed concentration, less nitric acid is lost at the higher temperatures. This statement is corroborated by Fig. 6, where the lower oxide vapor pressure increases with temperature much more rapidly than the nitric acid pressure.

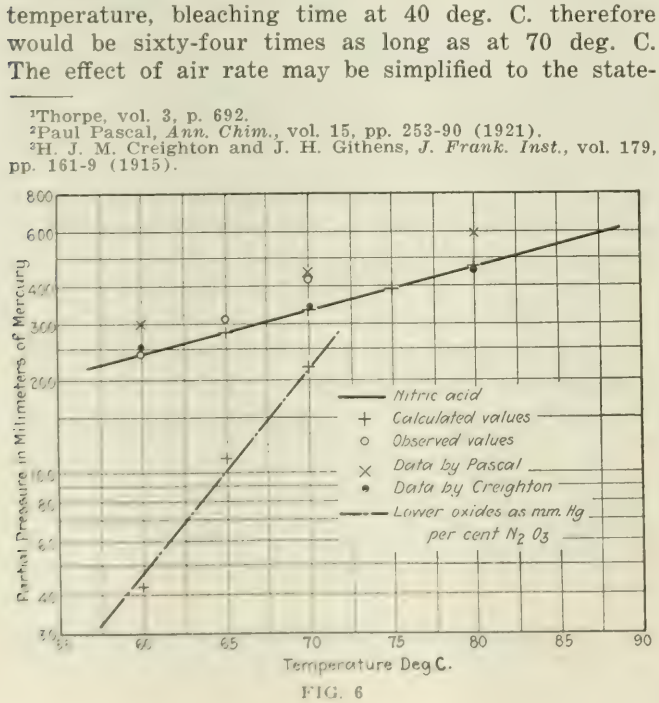

FIG. 6

Summary

(1) From theoretical considerations, the equation for the rate of bleaching of nitric acid by air is shown to be $\log_e \frac{N_2}{N_1} = -\beta(\theta_2 - \theta_1)$

(2) Three runs at constant air rate but varying temperatures and three runs at constant temperature but varying air rates proved this law.

(3) The rate of bleaching was found to be proportional to the rate of air flow and to double with each 5 deg. C. rise in temperature.

(4) The coefficients obtained in the above laboratory runs give calculated rates of bleaching which check observed rates in the plant with an accuracy of better than 10 per cent.

(5) The approximate vapor pressures of the lower oxides of nitrogen in nitric acid solution were determined for a 1 per cent solution.

(6) In bleaching nitric acid to a fixed concentration of lower oxides less nitric acid is lost at the higher temperatures, since the vapor pressure of the lower nitrogen oxides increases more rapidly with an increase in temperature than does the vapor pressure of HNO_3.

War Explosives in France

The Problems That Confronted French Chemists During the World War and a Review of Their Work in Developing New Explosives

By J. Cavalier
President of Toulouse University, France

FRANCE was handicapped in her war manufacturing by the situation in her chemical industry. It has been said that she had no great chemical industries and that she depended on other countries for her chemical products. This statement is not strictly correct, for France was independent in many instances, manufacturing an abundance of dilute sulphuric acid and even exporting a number of important products such as carbonate of soda, chlorides, chlorates, mineral coloring materials, superphosphates, essence of turpentine, tanning extracts, soaps, glycerines, etc.

The fact is that a real division of work between the countries had become established and in this distribution the industries based on organic synthesis were practically monopolized by Germany. Particularly was this true with respect to the aromatic compounds, especially dyes, for which, like most other nations, France was tributary to Germany.

Now it happens that the industry of coloring materials is closely related to that of nitro-explosives. A country which is fitted out to make the first is fitted out to make the second, for it has available the aromatic hydrocarbons, raw materials common to both industries. In France the production of coal was never above the immediate need of the country and consequently relatively few coke ovens were operated and many of these were not of the byproduct type. Therefore the production of benzene and toluene at the beginning of the war was altogether insufficient for the demand.

Regulation Explosives at Outbreak of War

At the time war was declared the regulation high explosives used in France for charging artillery projectiles were TNT, picric acid and trinitrometacresol. As the war went on, new projectiles came into use, such as hand grenades, trench mortar bombs, airplane bombs, etc., so that the demand rose from about 40 tons a day at the beginning to 1,064 tons. The raw materials for such large-scale production were lacking; it was necessary to find, study and use other explosives that could be substituted for these.

Solving the Problem

The situation called for relief either by increasing the development of natural resources, by the utilization of new raw materials or by the development and use of new types of explosives. Following the first two expedients, strenuous efforts were made to increase the national production of essential materials. New coke ovens were constructed in connection with the blast furnaces, which utilized the new iron ore of Normandy; byproduct recovery systems were installed in all the old and new coke plants and benzene was recovered from illuminating gas. In addition, the rectification of the so-called oils of Borneo was developed. These oils are complex mixtures containing hydrocarbons of the aliphatic series, analogous to those of ordinary petroleum and not nitratable, and aromatic hydrocarbons, including benzene, toluene and xylene. Their composition is variable, but it may be approximately expressed as benzene 5 per cent, toluene 13 per cent and xylene 7 per cent. The extraction of these substances in a pure state is not commercially feasible, but by successive rectifications the aromatic hydrocarbons are enriched and fractions are separated, each of which contains a single nitratable hydrocarbon mixed with non-nitratable aliphatic hydrocarbons of about the same volatility. By treating these fractions with nitric acid, a mono-nitro derivative is formed which may be easily separated by distillation. The mononitrotoluene thus separated is used as raw material for making TNT. The mononitrobenzene was used in the production of aniline, dyes and diphenylamine, the well-known stabilizer for smokeless powder. The mononitroxylene can be trinitrated in the same way as toluene to form xylite and although this explosive is less powerful than TNT, its utilization was considered and studied.

Another hydrocarbon which had not been used in France up to this time for war explosives, and of which notable quantities could be obtained, was naphthalene, $C_{10}H_8$. The mono-, di- and tri-nitro derivatives were prepared, each of them, as a matter of fact, being a mixture of isomers rather than a definite chemical compound.

Picric acid, the second-mentioned regulation explosive, is the trinitro derivative of phenol. Some work was done in the early days of the war in preparing the dinitro derivative directly from benzene without the intermediate phenol stage. Benzene is transformed into a mono-chlor substitution derivative by passing a stream of chlorine through it in the presence of iron filings, which act as a catalyst. By nitration, dinitro chlorbenzene is obtained; the chlorine is relatively mobile and the OH group can be easily substituted for it by saponification with caustic soda, which gives the dinitrophenol.

$$C_6H_6 \rightarrow C_6H_5Cl \rightarrow C_6H_3\begin{cases}Cl\\(NO_2)_2\end{cases} \rightarrow C_6H_3\begin{cases}OH\\(NO_2)_2\end{cases}$$

The dinitrophenol obtained was then by a further nitration to be transformed into picric acid. However, as it was possible to procure the necessary phenol elsewhere, the latter part of the operation was abandoned and the dinitrophenol was employed directly in the mixtures.

As for metacresol, which is necessary in making one of the three regulation explosives, it was not possible to increase the stock on hand; even by uniting the resources of the allied countries scarcely more than a few tons a day could be obtained, and this was absolutely insufficient. Trinitrometacresol is used mixed with melinite for the purpose, as will be described later, of lowering the fusion point. The same rôle can be played by other substances, especially dinitrophenol, so the latter was developed to some extent.

Thus, besides the raw materials formerly used—benzene or phenol, metacresol and toluene—it was possible to utilize two new ones, naphthalene and xylene; and to the three usual nitro-explosives—picric acid,

TNT or tolite, and trinitrocresol—were added xylite, mono-, di-, and tri-nitronaphthalene and dinitrophenol. The study of certain derivatives which had been investigated and proposed for certain purposes was also resumed: trinitro-anisol, trinitrophenetol, tetranitromethylaniline and hexanitrodiphenylamine.

All these derivatives involved about the same raw materials and hence did not increase the sum total of the country's resources. Moreover, their explosive properties were not such as to warrant undertaking new and complicated methods of manufacture. Hence they were not extensively developed. Instead, attention was directed to two other types of explosives, the nitrates and the chlorates. Considerable quantities of ammonium nitrate were available from the synthetic plants of Norway, and Chilean nitrate was also being imported. The manufacture of chlorates, especially sodium chlorate and ammonium perchlorate, presented no difficulties.

The third-mentioned expedient for relieving the chemical situation—that of developing and using new types of explosives—therefore followed these lines. A large number of available mixtures can be made by mixing the various substances mentioned above, the nitro derivatives, nitrates and chlorates. The problem would have been relatively simple had there been only the questions of resources and production methods with which to cope. But there were other factors to reckon with. While almost any of the combinations can be applied indiscriminately for explosives used in mining operations, this is not true for those employed in charging shells, where the safety factor is of such great importance. Besides, the effect to be produced must not be overlooked, as a different type of shell is required for use against troops than that used to break up trenches or to destroy barbed wire entanglements. Again, the method of charging and the available apparatus for this operation had to be kept in view.

Fundamental Properties of Explosives

In developing a new explosive the essential properties to be considered are its potential energy, its force, its sensitiveness and the speed of detonation.

The potential is the total amount of heat evolved by the reaction in a closed vessel; it is measured by means of a calorimetric bomb.

The force, or power, is determined by the maximum pressure developed by the explosion in a closed vessel, and is measured by means of a pressure bomb, a strong hollow cylinder of steel closed at one end by an electric firing device and at the other by a "crusher" gage. The pressure developed is transmitted to a copper cylinder and is measured by the amount of compression sustained by the cylinder.

For a given explosive, the pressure evidently increases with the "density of the charge"—that is, the weight of explosive per unit of volume. It is not proportional to this density, for it must become infinite when the volume occupied corresponds to the smallest volume which the products of decomposition (gases and solids, if such are formed) can have, however great the compression to which they may be subjected. This smallest volume per unit of weight is called the "co-volume"; it is the volume below which the decomposition products of 1 kg. of the explosive are not compressible.

Let α be the co-volume.
π the weight of the explosive charge.
V the volume occupied.

The pressure P is related to the charge by the equation:

$$P = \frac{f\pi}{V - \alpha\pi} \qquad (1)$$

or, substituting the density of the charge $\Delta = \frac{\pi}{V}$

$$P = \frac{f\Delta}{1 - \alpha\Delta} \qquad (2)$$

f is a constant for each explosive and characteristic of the force. It is the pressure produced by 1 kg. of explosive decomposing in a closed space equal to 1 cu.dm. plus the co-volume. In fact, if we put $\pi = 1$

and $V = 1 + \alpha$

in formula 1, we find $P = f$

With powerful explosives this force is of the order of 7 to 10,000 kg. per square centimeter. It depends on the quantity of heat and the amount of gas furnished by the decomposition.

Certain nitro- or nitrated explosives contain sufficient oxygen to transform all their carbon into carbon dioxide and all their hydrogen into water. The nitrogen is supposed to remain in the free state. Such explosives are said to be completely combustible. Nitroglycerine, with an excess of oxygen, is an example.

$$2C_3H_5O_3(NO_2)_3 \rightarrow 6CO_2 + 5H_2O + O + 6N$$

Such also is the case with ammonium nitrate explosives, such as schneiderite; the quantity of dinitronaphthalene has been adjusted so as to be completely burned by the oxygen of the nitrate.

$$(NH)_4NO_3 \rightarrow N_2 + 2H_2O + O$$

This does not apply to all explosives, however. Nitrocellulose has approximately the formula $C_{12}H_{14}O_{10}(NO_2)_6$ or $C_{12}H_{14}N_6O_{22}$. To give $12CO_2 + 7H_2O$ it would require 24 + 7, or 31O, whereas we have but 22. Picric acid is $C_6H_3N_3O_7$. The molecule contains 7O, while complete combustion would demand 12 plus 3/2.

Hence, when these compounds decompose, considerable amounts of carbon monoxide are formed which can poison the air in the dugouts. With picric acid there may be a considerable amount of carbon liberated, producing a black smoke. However, the completely combustible compounds are not always the most efficacious. For example, the nitro derivatives of the picric acid class, far as they are from complete combustion, are generally more powerful than the mixtures of the schneiderite type. In the new mixtures studied during the war it was those which by incomplete combustion would yield carbon monoxide that were chiefly sought.

For nitro derivatives of the same type, the power increases as the ratio of the number of nitro groups to the number of carbon atoms in the molecule. Thus, trinitrotoluene, $C_6H_2(CH_3)(NO_2)_3$, is more powerful than the dinitro compound and more powerful than trinitroxylene, $C_6H(CH_3)_2(NO_2)_3$.

Sensitiveness

The greater or less ease with which an explosive substance detonates when subjected to friction or shock is its sensitiveness, a quality of capital importance which merits consideration, not only in regard to use of the explosive but also for handling it during the process of manufacture and in transportation. A very simple experiment will give a clear conception of its nature. A metallic weight is permitted to fall from various heights on a small quantity of the explosive in a capsule. The minimum distance through which the weight may be

dropped and still produce detonation is a measure of the sensitiveness of the explosive. Fulminate of mercury is extremely sensitive, while ammonium nitrate mixtures and picric acid are much more resistant to shock and friction. The salts of picric acid, however, particularly the alkali picrates and lead picrate, are extremely sensitive.

For a given explosive, the sensitiveness depends to a certain degree on its physical condition. It is greater in a mass of crystals which can rub against one another and it is diminished by making the mass more compact, especially by fusing and hindering the formation of larger crystals during subsequent cooling. It is also lessened by imbedding the crystals in a plastic substance which separates them. Thus melinite is imbedded in paraffine to render it less sensitive to rough handling.

Velocity of Detonation

Certain more sensitive substances detonate on being lighted. Such is always the case with lead picrate and mercury fulminate. The latter is used as a primer; the explosion wave produced by the detonation of a very small quantity of fulminate (about 2 grams) is transmitted to the explosive to be detonated. If this should not suffice, as in the case of resistant explosives, a relay is employed which consists of a certain quantity of explosive of medium sensitivity. The detonation must spread throughout the whole mass of the explosive.

The speed with which the detonation spreads through a given explosive is not a constant; it varies with the amount of tamping. A very simple method due to a French engineer, Dautriche, enables us to determine the relative velocity of detonation as compared with a standard velocity, that of a rod or string of melinite. The explosive under investigation is placed in a metallic tube T about 10 cm. long. At two well-defined points B and C are the ends of a strip or cord of picric acid, BCD. Each of these ends is provided with a charge of fulminate. The explosion is initiated by a third fulminate charge at A. The wave travels to B and then to C. The strip of explosive is laid out on a plate of lead; the two explosion waves originating at and traveling from B and C move in opposite directions through the strip and at the point where they meet produce a transverse furrow at E.

If the two fulminate caps B and C were discharged at the same time, the furrow would be made at the midpoint D of the strip, a point which is marked exactly at the beginning of the experiment. A slight lag between the detonation of B and C, however, will cause a displacement of the furrow to E. This displacement, DE, is measured carefully and will be represented by e. The distance between the two caps B and C is also measured and called l.

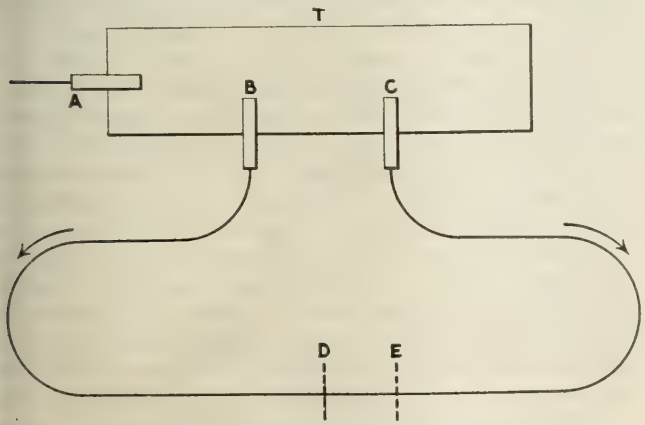

DIAGRAM OF APPARATUS FOR TESTING VELOCITY OF DETONATION

Let L = length of strip BD.
v = the velocity of the detonation to be measured.
V = the velocity of detonation in the strip.

The times of travel of the two explosion waves BDE and DCE are equal. Therefore,

$$\frac{L+e}{V} = \frac{l}{v} + \frac{L-e}{V}$$

or

$$\frac{2e}{V} = \frac{l}{v}$$

Whence

$$\frac{v}{V} = \frac{l}{2e}$$

The velocity V in the cord of melinite as measured by a direct method is about 7,000 meters per second. The maximum velocity of detonation of nitro explosives lies between 6,000 and 7,500 meters per second; that of schneiderite and other nitrate explosives between 5,000 and 6,000 meters; that of chlorate explosives between 3,500 and 5,000 meters.

Density Limit

Let us study a nitrate or chlorate explosive under different degrees of tamping or compression. Untamped, the material has generally but a low velocity of detonation: it increases with tamping and hence with the density up to a certain degree of compression, beyond which it diminishes rapidly and the detonation is no longer transmitted. The density corresponding to the maximum velocity is called the "density limit" under the conditions of the experiment. This point is of great importance, for if, in charging, this limit is overstepped, the explosive could not be detonated.

The density limit has not a fixed value for a definite explosive; it increases with the dimensions of the receptacle and the resistance of the containing walls. Thus, in the open air, schneiderite will not detonate unless its density be somewhat greater than 1; in a tube of copper, 2 cm. in diameter and with a wall-thickness of 1 mm. similar to those used in the method of Dautriche, the density limit is 1.45 to 1.50; it is over 1.50 in a 75-mm. shell and 1.6 in a 155-mm. shell.

Nitro explosives (picric acid, tolite, etc.) have, so to speak, no density limit; the velocity of detonation only becomes irregular as a result of great compression—4,000 kg. per square centimeter (density 1.7).

The properties and determinations described form the basis for the choice of explosives for producing any desired effect. For shells to be used against troops the charge should break the envelope into a large number of fragments which will act as so many separate projectiles. Therefore a very powerful explosive is required and a very sudden detonation. The nitro explosives fill this requirement admirably.

On the other hand, there is no need of great velocity of detonation to destroy trenches, power and potential energy being the qualities desired. Nitrate explosives which are slower, and some of which evolve more heat, will often do more effective work on the ground than nitro explosives.

For mining operations a great variety of formulas may be used. It is quite feasible to control the charging density to give the desired detonation.

The use of explosives in projectiles, especially in projectiles for artillery of high initial speed, presents other important problems. The velocity of such a projectile rises from 0 to 500 meters per second in about 0.01 second. Besides, it generally takes a rotary motion. The effect of inertia on the explosive contained in the shell will have a tendency to produce friction between the particles and consequently ignition and premature explosion followed by rupture of the gun or at least serious damage.

For use in projectiles the charge mass must be stable and free from any tendency to shift or become displaced. To this end it is necessary that the material be compact, without open spaces after the charging, and have no tendency to form them at the firing of the shot. At that instant, the interior charge is pressed against the base of the shell with a force that can readily be conceived. The phenomenon is called the set-back.

If S be the exterior surface of the base of the shell, P the maximum pressure produced by combustion of the powder, the force acting on the shell is PS.

Let M be the mass of the shell, G its acceleration.

Then $PS = MG$.

Let p be the weight of the shell and g the acceleration due to gravity.

Then $p = Mg$

Whence $$PS = p\frac{G}{g}$$

$$G = g \times \frac{PS}{p}$$

Calculation shows that the acceleration G of the projectile is greater the smaller the caliber. For a 75-mm. shell, G equals 17,000 g. That means that the charge, as well as each part of the shell, at the moment of starting, weighs about 17,000 times its ordinary weight. By multiplying the acceleration by the total weight of explosive and dividing by the cross-section of the interior, we obtain approximately the pressure to which the layer of explosive on the base is subjected. This is called the pressure due to the set-back. In the 75-cm. shells its maximum value is about 900 kg. per sq.cm. Under this pressure the explosive material is compressed to a density which we may determine by subjecting a small portion of the explosive to the same pressure in a cylindrical mold and measuring the density of the compressed mass. The preliminary tests must necessarily be verified by density measurements made on charged, but unprimed, projectiles that are actually fired. A surcharge of propellant is employed to give the desired margin of safety. The unexploded shell is recovered, opened and the density of the charge at the base is measured.

This is the density that must be reached in charging. If not, it will be reached in firing the backward displacement of the charge toward the base which, as we have said, might cause a premature explosion. The density thus determined and which must be realized in charging is then compared with the "density limit" of the explosive—that is, the density beyond which the detonation is no longer transmitted. If the "density limit" has been overstepped, the explosive under investigation must be abandoned for the caliber intended.

To realize these necessary conditions—low sensitiveness, compactness, sufficient density—two methods of charging are employed: Compression and fusion.

The shell is filled with the powdered explosive and rammed down by hydraulic pressure. This process produces compact charges, but is too slow for intensive production. Picric acid shells were loaded this way, a mixture of 88:12 picric acid:paraffine being used. The paraffine incloses the crystals reducing the sensitiveness and gives the necessary plasticity for the compression without hindering the detonation, the latter being accompanied by a fulminate primer and a relay of picric acid crystals properly tamped. This combination was used for shells of medium and large caliber.

Ammonium Nitrate Explosives

Since 1888, the Service des Poudres had manufactured an explosive composed of 87.5 per cent of ammonium nitrate and 12.5 per cent of dinitronaphthalene for use in mining operations. This explosive, on complete combustion and sudden decomposition, yields a large volume of gas, the final temperature of which is not very high so it is a safe explosive for use in mines where firedamp prevails. It was not employed by the French artillery, but had been utilized by the Schneider company to charge projectiles which it sold to foreign countries and which were used especially in the Balkan war. Hence the name "schneiderite," by which it is known. Thus it was an explosive that had been studied, had been tested for war purposes and had given satisfaction. One of its drawbacks was the fact that ammonium nitrate is hygroscopic and the explosive must be protected from moisture.

An analogous but more powerful mixture consisting of 77 per cent ammonium nitrate with 23 per cent xylite was also used. Sodium nitrate may be substituted for the ammonium salt, although it produces a smaller volume of gas and forms an explosive with less shattering power than schneiderite; but for large caliber shells and for clearing ground it gives satisfactory results.

TABLE I—COMPOSITION OF PROJECTILE EXPLOSIVES

Constituent	Per Cent									
NH_4NO_3	87.5	77	70	80	85	50	50	50	50	50
$NaNO_3$	....	..	..	..	..	30	30	30	30	30
Dinitronaphthalene	1.25	..	..	..	10	..	..	..	..	..
Trinitronaphthalene	....	..	..	20	..	20	..	..	15	15
Xylite	....	23	..	..	..	..	20	..	5	..
TNT	....	..	30	..	5	..	..	20	..	5

Of the new combinations tried and tested, a number were considered satisfactory and held in reserve. These formulas are summarized in Table I.

Charging in Fused State

Most of the explosives charged in this way are nitro compounds either alone or in mixture. The explosive is melted in a bath of boiling water or glycerine and is poured directly into the shell. These melted explosives, after solidification, usually have a greater density than would be needed to prevent displacement on firing of the shell. Thus one of the essential conditions of proper charging is attained. It is necessary only to avoid free spaces and hollows which may form by contraction when the material solidifies, especially in the upper portions.

As before mentioned, an explosive fused into a compact homogeneous mass is generally less sensitive to shock than when in the powdered condition. That is an advantage, but care must be taken to prevent the formation of crystals during the solidification. To this end the material is stirred with a wooden ladle after solidification begins, so as to interfere with crystal formation. This operation is called "touillage" (stirring). Single compounds used alone, such as picric

id and TNT, have a tendency to form large crystals, ndering the process quite risky. On the contrary the ndency to crystal formation is much less marked in ixtures, especially eutectic mixtures.

Xylite, or TNX, melts at 170 deg. C. and cannot be ed alone for charging in the fused state. Mixing ith other substances not only lowers the boiling point t brings about a particularly fine and homogeneous ructure, favorable to safety. It is not always possible use a eutectic mixture, however, for the melting point ay be brought below that prevailing in munition pots.

Table II gives the proportions of some fused explo- ves which have been studied and pressed into service could have been used if the need had developed.

ABLE II—PROJECTILE EXPLOSIVES CHARGED IN FUSED STATE

	Composition—Per Cent													
cric acid	100		40	80	60	70	55	55	50	80	60		50	60
initrocresol			60				10	10						
initrophenol					40		35				10	90		30
NT		100						35			30	10	40	
ylite										20			10	10
ononitronaphthalene						30			50					
initronaphthalene				20										

Ammonium nitrate melts at 166 deg. C., at which emperature it also starts to decompose. The melting oint is lowered by mixing with sodium nitrate or am- ionium thiocyanate, NH_4SCN, which also aids combus- on. The formula used was:

Ammonium nitrate	71 per cent
Sodium nitrate	5 per cent
Ammonium thiocyanate	11 per cent
Powdered aluminum	13 per cent

The mixture of salts is first fused alone and then the luminum is mixed in by simple stirring. This explo- ive may be poured at temperatures below 130 deg. C. nd is used in shells of large caliber.

Chlorate Explosives

The alkali chlorates and perchlorates are explosive ompounds, but on account of their sensitiveness the anger of handling them is great, and this stood in the ay of large-scale production for a long time. It is nly within the last 20 years that the problem has been olved by incorporating the salts in a combustible mate- ial of plastic nature. This material is melted, the hlorate mixed in by processes involving a minimum mount of friction and the mixture is then cooled. The lastic material may be a solution of nitrated hydro- arbons in castor oil, or simply paraffine or vaseline, ats, or a mixture of such substances. The use of this lass of explosives for war needs had a peculiar interest or France.

The preparation of chlorates and perchlorates is rela- ively simple. It involves none of the materials needed or other explosives; no hydrocarbons or nitrates; no oncentrated nitric or sulphuric acids. The essential aw material is sodium chloride, which France pro- uces in abundance from salt marshes and mines. An- ther requisite is electric energy. France is well sup- lied with water power, which was in great demand for umerous other war products—chlorine, calcium car- ide, aluminum, ferro-alloys, chromium, manganese, pecial steels. It was possible, however, to divert a ufficient amount for chlorate manufacture.

Unfortunately, however, the chlorates are more sensi- ive to shock and friction than the other two classes (nitro-compounds and nitrates) and for this reason could not be employed in projectiles of high initial velocity in which the charge undergoes a sudden and violent compression at the instant of departure from the gun. Hence this class of explosives was reserved for mine opertions and for projectiles of low initial velocity—for instance, in hand grenades, aviation bombs and trench mortar shells.

Conclusion

Such were the problems that confronted the French chemists at the beginning of the war and such were the steps taken to solve them. It has been shown in a general way how much preliminary work is necessary to develop a new explosive. A long series of preliminary investigations is necessary; first of all in the laboratory, to determine the characteristic properties, heat evolved, pressure developed, sensitiveness, velocity of detonation, melting point and other empirical tests approximating the conditions in practice, such as the enlargement produced in a hollow block of lead or in the earth, or the crushing of a lead cylinder. Then the investigation must be carried over to actual use; charging shells, safety test by actual firing, proper charging density by examination of material in re- covered shell, fragmentation, volume of shell holes pro- duced, etc. The results of this work were such that the French army was able to meet all contingencies, as far as ammunition was concerned.

Acetone as a Solvent for Varnish-Gums, Resins and Shellacs

A critical examination of the solvent properties of acetone, produced by the destructive distillation of cal- cium acetate, is being conducted at the Mellon Institute of Industrial Research of the University of Pittsburgh, Pittsburgh, Pa., in order to ascertain its value as a commercial solvent.

In the course of the work on the solvent properties of acetone, a number of gums, shellacs and natural and artificial resins have been investigated. The percentage of acetone-soluble material in water-gums was found to be considerably less than in copal resins. The former contained from 7 to 17 per cent of acetone-soluble material, while the solubility of the latter class of gums varied from 30 to 100 per cent in the same solvent. The solubility of water-gums at room temperature was found to be quite low, while the copal resins tested were either miscible in all proportions or in a concentrated solution with a separation on dilution. The solubility of shellacs and resins varies somewhat with the grade of product. The WW grade resin is entirely soluble and miscible in all proportions, while inferior grades contain different amounts of insoluble material: the part soluble, however, is miscible in all proportions at 25 deg. C.

It was noted that the addition of another solvent, as methanol, to acetone greatly increased its solvent prop- erties. Acetone was found to be miscible in all pro- portions with all the ordinary commercial solvents tested, thus permitting composite solvents to be had, the solvent power of which greatly exceeds that of the individual solvents.

The present grade of acetone obtained from calcium acetate is of excellent homogeneity and uniformity. Its low specific gravity gives it a larger volume per pound and thus lowers its price per gallon when compared with a number of ordinary commercial solvents.

Mechanical Properties Of Commercial Iron

Definitions of Various Terms Used in the Art of Testing Materials, and a Discussion of How Various Circumstances Surrounding the Test Affect the Results on Annealed Bars of Common Structural Metals

By Zay Jeffries and R. S. Archer

BROADLY speaking, the mechanical properties of metals are those properties which describe the behavior of metals in the mechanical arts. The conditions to which metals are subjected, both in service and in the fabricating processes which precede service, are of unending variety, so the engineer is confronted with the problem of determining the suitability of metals for the various conditions of fabrication and of service. It is to meet this problem that the science of mechanical testing has been developed.

The most certain evidence of the behavior of a metal under a given set of working conditions consists in the accumulated results of many trials under those conditions. Actual working conditions are often very complex, however, and the accumulation of such evidence is a long, slow and costly process. It is, therefore, desirable to analyze the complex conditions into a relatively small number of more simple elements. The common tests of metals, such as the tensile test, are designed to determine these more elementary properties.

Complexity of "Simple" Properties

A mechanical test is merely a mechanical operation in which the variables are controlled and the results quantitatively measured. The smaller the number of independent variables the more easily are they controlled and hence the greater the accuracy of the test and the more fundamental the nature of the property disclosed. Considering our "simple" mechanical properties of metals in this light, we find that they are quite complex in comparison with the properties regarded as fundamental physical constants. The melting point, for example, of a metallic element is sufficiently fixed for practical purposes to be regarded as absolute. Pressure and grain size exert a slight but negligible influence. The tensile strength, on the other hand, cannot be stated with satisfactory accuracy even for a pure metal without defining the temperature, structure of the metal, form and size of test piece, and rate of loading.

There is, therefore, a need for still further simplification in testing—that is, for further analysis of the common mechanical properties and the defining of properties of a more fundamental nature. Such an analysis must be made with the assistance of all the knowledge afforded by metallography of the structure of metals, and the effects of deformation and temperature on structure. Attempts have been made and are unfortunately still being made to solve these problems by pure mathematics.

The analytical method is of course limited. Even if it were possible to define all of the fundamental constants upon which the mechanical properties of metals depend, and to determine them, the synthesis of these elements into results of direct utility would undoubtedly present such difficulties that in many cases the empirical method of attack would be more easy and more certain. Such a knowledge of fundamentals would be invaluable, however, in classifying empirical information and in pointing the way to new knowledge.

It is almost needless to say that a fundamental study of the properties of metals and alloys should begin with the pure metals. There has nevertheless been some tendency to give the properties of the pure metals less attention than they deserve, perhaps because of failure to recognize their true complexity. While it is true that metals are most widely used in alloyed form, it is also true that a fundamental understanding of the properties of the alloys requires an understanding of the properties of the pure metals upon which they are based.

Classification of Properties

All of the mechanical tests consist in observing quantitatively the behavior of metals under stress, the various tests being differentiated by the type of specimen and the manner and rate of application of stress. According to the rate of application of load, tests are often divided into two classes, called "static" and "dynamic." The so-called static tests include the ordinary tension, compression, torsion and transverse tests, as well as the Brinell hardness test. The Shore scleroscope test for hardness would also probably be classified as a static test. The dynamic tests include the various types of alternating stress or fatigue tests and the single and repeated blow impact tests. (Another division is sometimes made into static tests, repeated stress tests and impact tests.)

The effects of stress are deformation and rupture. The mechanical properties of metals may be classified in a general way in three groups, describing (1) *resistance* to deformation and rupture; (2) *capacity* for deformation without rupture; and (3) *work* of deformation or rupture.

In the first group, which may be designated by the general term *hardness*, are included the elastic limits, elastic moduli, tensile strength, transverse strength, shearing strength, endurance limit under repeated stresses, Brinell hardness, scleroscope hardness, etc.

The second group may be covered by the term *plasticity*, and includes the elongation and reduction of area in the tensile test, the relative compression without rupture in the compression test, the angle of twist in the torsion test, the deflection at failure in the transverse test, angle of bend in the bend test, as well as the general properties denoted by the terms ductility and malleability.

The work of deformation and rupture is the product of the resistance to deformation by the amount of deformation, and can be calculated from the complete data of any test in which both load and deformation are observed continuously or at close intervals. It is represented by the area under the stress-strain curve. The only common test in which the work is measured directly is the single-blow impact test.

In a test specimen subjected to simple stress, as ten

on or compression, the energy of deformation is applied uniformly to all of the metal under test, as long as the deformation is elastic. The energy is stored as elastic energy, recoverable on removal of the load, and is called *resilience*. The work expended in deforming unit volume of a material to its elastic limit is the modulus of resilience.

When the elastic limit is exceeded, plastic deformation may take place in a fairly uniform manner, as when a tensile specimen draws out evenly without necking. The work of permanent deformation may then be calculated per unit volume of the metal. When the deformation ceases to be uniform, as when necking occurs, it is no longer possible to refer the energy to a definite volume of metal. Supposing the stress-strain diagrams of two tensile test-bars to show the same total work of rupture, the maximum energy absorbed per unit volume of metal will be in the bar having the greater reduction of area.

Cause of Hardness and Strength

Metals owe their resistance to deformation to the forces between the atoms. These forces are both attractive and repulsive, and are directional. The repulsive forces are manifested by the resistance of metals to hydrostatic pressure by which the atoms are forced closer together in all directions. Under ordinary compression loading, the atoms are forced together in the direction of the compression but apart in the direction of the secondary tensile stresses. Under direct tension the distances between atoms are increased in the direction of the load and decreased in the direction—at right angles—of the secondary compressive stresses. There is no condition of loading corresponding to a negative hydrostatic pressure, under which the interatomic distances would be increased in all directions.

Any permanent deformation of a metal involves changes in the relative positions of some of the atoms, and, therefore, the breaking, temporarily at least, of some interatomic "bonds." The rupture of any material, whether with or without permanent deformation, also involves the breaking of interatomic bonds. The greatest possible resistance that a material can offer to deformation or rupture is the summation of all the interatomic bonds on a plane through the specimen normal to the stress, a summation which may for convenience be termed the "absolute cohesion" of the material. Actually such a summation of forces is never realized, because rupture always takes place by degrees, and the breaking of atomic bonds is not simultaneous. The tensile strength of a material merely represents the maximum number of atomic bonds that come into play simultaneously during the test.

Absolute cohesions of metals are far in excess of the values obtained for tensile strength. A qualitative illustration of this fact may be found in a consideration of some properties of pure iron. The tensile strength, after hot-rolling, is about 40,000 lb. per sq.in., a value representing as usual the maximum load divided by original cross-section. If the actual reduced area of the test-piece is measured throughout the progress of the test and the stress computed on this basis, a value will be found for the maximum stress which is much higher than the tensile strength. The maximum stress will then be about 80,000 lb. per sq.in. Severely cold-worked iron may show a tensile strength of 150,000 lb. per sq.in. The maximum actual stress is again somewhat higher (165,000), but not in so large a ratio as in the case of the hot-rolled iron. Even in the cold-worked iron, rupture still takes place by degrees—that is, by a kind of tearing action—so that the highest of these figures still does not represent the inherent absolute cohesion.

Some very interesting tests of glass have been reported by Griffith[1]. In ordinary fibers of 0.040 in. diameter the material had a tensile strength of about 25,000 lb. per sq.in. The tensile strength was found to increase as the diameter of the fibers decreased, and in very fine fibers, carefully prepared, surprisingly high values were obtained. The maximum strength recorded was 498,000 lb. per sq.in. at a diameter of 0.00016 in. Plotting the reciprocal of the tensile strength against the diameter of the fiber and extrapolating to zero diameter, Griffith found a value of 1,600,000 lb. per sq.in., representing the theoretical "absolute cohesion" of the glass.

Calculations based on the energy required to separate the atoms of metals by vaporization give values up to about 5,000,000 lb. per sq.in. for the "intrinsic pressure," a quantity which is theoretically of the same order of magnitude as the absolute cohesion.

The accuracy of Griffith's extrapolation and of values for cohesion derived from the heat of vaporization may be questioned. The actual numerical values reached are of little significance. The important thing is that metals possess very great inherent cohesion, greater probably than is ever realized in tensile tests of the pure metals or their strongest alloys. Looked at from this point of view, the problem of the hardening and strengthening of metals by various means becomes more simple. Instead of inquiring why metals are so strong, we may better ask why metals are so weak.

Nature of Plasticity

Permanent deformation of any material involves displacements within the material, during which the cohesion is overcome between the parts undergoing relative displacement. The property of plasticity depends upon the ability of such displaced parts to re-establish cohesion in their new positions. This ability is a conspicuous characteristic of liquids, and the plasticity of many materials depends on the possession of a structure like that of liquids, or on the presence of some liquid, to preserve continuity during deformation. Glass is a typical example of undercooled liquid which at certain temperatures is distinctly plastic. Even after cooling to temperatures of great rigidity its structure is still that of a liquid, in the random arrangement of molecules. Clay, on the other hand, owes its plasticity to the presence of a continuous matrix of water which holds together the fine particles of non-plastic solid matter.

According to the amorphous metal hypothesis of Beilby, metals preserve their continuity during plastic deformation by the generation of fluid amorphous films on the surfaces of slip. On this basis the plasticity of crystalline materials depends on their ability to generate such amorphous films. It is quite conceivable, however, that crystalline fragments might adhere to each other without the intervention of a layer of undercooled liquid or vitreous amorphous material.

Complexity of structure is opposed to plasticity. The molecules of a liquid establish cohesion bonds with each other easily without the necessity of any particular arrangement. Hence two bodies of a given liquid unite with each other on contact. When contact is brought about between two solids whose rigidity depends upon a highly organized structure, the establishment of cohesion is not so easy. When a piece of wood, for example, is broken in two, it is practically impossible to replace the parts either in their original positions or in any other positions in which cohesion is re-

[1] "The Phenomena of Rupture and Flow in Solids," A. A. Griffith, *Phil. Trans.*, Series A, vol. 221, pp. 163-198.

established. In metals the structure, though crystalline, is relatively very simple. It is easily imagined that the fragments of a metallic crystal broken along a crystallographic plane might be brought into contact on this plane in perfect registry so that the original space lattice, and hence cohesion, might be re-established. Probably plastic deformation of metals involves both this type of junction and junction by more or less disorganized or amorphous metal. The monatomic condition of aggregation of the metals and their simplicity of crystalline structure favor both mechanisms.

Common Properties of Commercial Iron

In Table I are given the common mechanical properties of a very pure grade of iron, in the annealed condition after working. The tests were all made at ordinary temperatures and under usual conditions. Besides giving useful information about this most important metal, these figures will serve to illustrate a brief discussion of some of the mechanical properties.

The elastic and proportional limits are practically identical. Difference in the values given reflects chiefly the difficulty of an accurate determination: the actual results obtained depend on the sensitivity of the measurements of extension. When metals are tested at temperatures well below that of recrystallization, the passing of the elastic limit represents the beginning of plastic deformation by transcrystalline slip. At temperatures near or above the recrystallization temperature, intergranular flow may take place and mark the elastic limit; the stress required varies greatly with the time of application.

The yield point is well marked in iron and mild steel, representing a considerable extension at nearly constant stress. During this stage the formation of slip-bands is general throughout the specimen; the effect is visible on the machined surface of a test-bar, which becomes dull. In non-ferrous metals the yield point is not nearly so well marked and can be defined only as the stress at which some arbitrarily selected extension occurs.

Up to the elastic limit the metal is unaffected by the application of the test load. Beyond this point, however, the deformation incident to the test alters

TABLE I—PROPERTIES OF ANNEALED ARMCO IRON

Property	Value	Remarks
Elastic limit in tension, lb. per sq.in.	14,400	
Proportional limit in tension, lb. per sq.in.	16,100	
Yield tension, lb. per sq.in.	19,000	
Ultimate tensile, lb. per sq.in.	42,400	½ in. diameter specimen

Brinell hardness number*	75	
Shore scleroscope hardness	18	
Energy of rupture on impact, ft.-lb.	19.3	Specimen 0.394 in. square, notched to ¼ depth, bottom of notch 0.04 in. radius.

* With the exception of the properties marked with asterisk, the results given in this table were reported by H. F. Moore, Eng. Exp. Sta., Univ. of Ill.

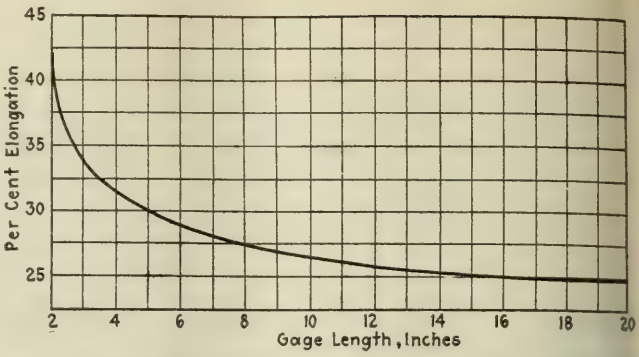

FIG. 1—EFFECT OF GAGE LENGTH ON ELONGATION OF SOFT STEEL
Test piece 0.688 in. diameter

the structure and properties of the metal. Elongation, reduction of area and tensile strength therefore depend not only on the original condition of the metal but also upon the effect of the testing operation itself. The mechanism and effects of plastic deformation must be considered in interpreting the results of tests in which the metal is plastically deformed.

General and Localized Elongation

Most of the ductile metals draw down at the point of fracture so that the relative elongation at this point is greater than the general relative elongation along the bar. Total elongation as measured is, therefore, made up of two parts, one a general elongation approximately uniform along the bar and the other a variable local stretch where the bar necks down. The maximum local stretch can be calculated from the reduction of area on the assumption that the volume of the metal remains constant (which is practically true). When the reduction of area is high the per cent elongation on the constricted portion of the bar may be several times the per cent general elongation. Hence on bars of the same cross-section, the per cent elongation, measured so as to include the fracture, is greater the shorter the gage length. (See Fig. 1.) If the gage length remains constant but the test-bars differ in cross-section, then the per cent elongation is greater on the larger bar, as illustrated by the values given in Table I. The gage length is 2 in. in each case. On the ½-in. test-bar the per cent elongation was 48.3, made up largely of the local stretch at the fracture. Wire of 0.025 in. diameter showed elongation of 23.7 per cent, representing almost solely the general elongation—since the contribution of the small local stretch is in this case negligible.

Reduction of area in tension is characteristic both of the metal and the conditions of test. General elongation is to a similar extent characteristic of the metal; elongation as commonly measured, however, includes a factor which is proportional to reduction of area. Reduction of area and general elongation are not affected in the same way by changes in temperature and other variables. Since the measured elongation includes both factors, it will be found that the effect of temperature and other conditions depends largely on the ratio of gage length to cross-section. The relative elongation found by the tensile test is the most common criterion of ductility, the general elongation being probably a better indication than the total elongation measured over a short gage length.

Ductility and Malleability

Ductility is capacity for being drawn out, or plastically deformed, by direct tensile load without rupture.

is a property which requires both plasticity and tensile strength, and does not, therefore, necessarily reach a maximum value when plasticity is at a maximum—most metals have the greatest plasticity above the recrystallization temperature, but greatest ductility below the recrystallization temperature; they have not sufficient tensile strength above the recrystallization temperature to sustain the loads necessary to draw them out. Malleability is capacity for plastic deformation without rupture by hammering. It does not require as much resistance to tension as does ductility, since the metal is not subjected to the entire deforming load in direct tension. Secondary tensile stresses are developed, however, of greater or less magnitude depending on such factors as the manner of hammering and shape of dies. Some strength is therefore required, in the absence of which the metal is said to be "tender." The process of drawing out by swaging in confined dies is less exacting on the strength of the metal than are most forms of hammering, and can often be carried out when successful working by hammering is not possible.

There are no fixed standards of plasticity, ductility and malleability. In fact, these properties are so loosely defined that they cannot be expressed accurately even in relative terms. While the term plasticity refers chiefly to *capacity* for deformation, it also carries some implication of *ease* of deformation. Consider iron, for example, at the temperatures 1,000 and 1,100 deg. C. At either temperature it can be plastically deformed to an almost unlimited extent. It is softer at the higher temperature, however, and would commonly be considered more plastic. Since it can be deformed more easily by hammering or rolling at the higher temperature, it would also be generally considered more malleable. Ductility refers more definitely to capacity for deformation by drawing, but there are various ways of estimating such capacity. Some of the older tables in which the metals are arranged in the order of ductility are based on the fineness of the wire which can, or rather has, been drawn, just as the tables of malleability are based largely on the thinness of the sheet or foil that can be beaten. Another criterion is the total reduction in section, or extension in length, possible by drawing without intermediate annealing; on this basis copper is much more ductile than iron at room temperatures. Relative ductility is also sometimes measured by the maximum reduction possible in the first die or the first few dies. In this respect iron is more ductile than copper.

It will be noted in Table I that the tensile strength of the iron wire is about 14 per cent higher than that of the ½-in. test-bar. Presumably the two materials are similar as to structure, and the difference in strength is in accordance with the general observation that tensile strength increases as the diameter of the material decreases. This has been recognized in standard specifications for wire.

It is remarkable that this material showed an endurance limit under repeated stress about 60 per cent higher than its elastic limit in tension. Although there is no general law connecting endurance limit with the static properties, the endurance limit is usually less than the elastic limit in tension. It may be remarked in passing that the endurance stress of 26,000 lb. per sq.in. given in the table was calculated from the formula for a transversely loaded beam, which depends upon the assumption of perfect elasticity, yet the calculated stress is well above the known initial elastic limit of the metal.

Rate of Loading

Time plays an important part in the behavior of metals under stress. Thurston[2] divided metals and alloys into two classes according to whether or not they exhibited flow under prolonged application of stress. At ordinary temperatures, iron will sustain indefinitely any load which it will sustain for a short time. Many of the non-ferrous metals, however, especially the softer metals, like lead, tin and zinc, yield gradually under constant load; in the course of years, lead roofing will creep under its own weight.

Variations in the rate of applying load in the ordinary tensile test have a marked effect on both tensile strength and elongation of soft metals, which are as a rule increased by increasing the rate of loading. Ordinary variations in the rate of testing have practically no effect on the tensile properties of iron and steel. Under extremely rapid loading the elongation may be increased. Some tests have been reported by Maitland[3] on a steel which had a tensile strength of 58,000 lb. per sq.in. with an elongation of 27 per cent in 2 in. when broken in the usual manner. A specimen was screwed in blocks arranged so as to fall vertically in a slide for a certain distance, when the top block was arrested by stops and the specimen was broken by the momentum of the lower block. Broken in this manner the elongation was 47 per cent. The rate of loading was still further increased by driving the ends of the test-bar apart by exploding gunpowder or guncotton. Under these circumstances the elongation was up to 62 per cent. Such increases by rapid loading are not always obtained.

Instead of causing failure at a low stress, extremely slow loading of iron causes a considerable increase in tensile strength. Wires broken after a gradual application of load during about 2 months gave a tensile strength about 25 per cent higher than that obtained in a quick test. This behavior, which is peculiar to iron in its magnitude, will be discussed later and correlated with other properties.

Time plays an unimportant role in causing fatigue, especially in iron and steel. Thus the metal can be subjected without failure to a static load much greater than its endurance limit under repeated stresses for a period of time greater than that required in the fatigue test. It is the reversal of deformation rather than the prolonged application of load that does the damage.

There has long been a rather general belief that metals, particularly iron and steel, break more easily under suddenly applied load—i.e., shock or impact—than under slowly applied load. Impact tests have been made on rails and axles as a matter of routine inspection, to determine their susceptibility to easy fracture by shock. Several types of impact testing machine have been developed; the most common one breaks a notched bar by a single blow and measures the energy of rupture. It has been shown that for many kinds of steel the energy absorbed is practically the same whether the bar is broken in the impact machine or by slow bending. In other words, the test is merely a bend test of a notched bar. Some steels, however, appear to break much more easily by rapid than by slow bending.

Leasing of Equipment to Dealers Not Unfair Competition—Court Discusses Competition

In the case of the Sinclair Refining Co. against the Federal Trade Commission, the Circuit Court of Appeals set aside the order made by the commission against the Refining company and an appeal by certiorari was made to the United States Supreme Court. (42 Sup. Ct., 183.)

Complaint by Federal Trade Commission

The substance of the complaint against the Refining company was that it leased for a nominal consideration its oil pumps, storage tanks and containers and their equipment to persons who purchased oil from it with the understanding that same should not be used by the lessees to hold or pump the oil of any competitor. It was also charged that the leases were made on consideration that lessees should not purchase or deal in the products of a competitor.

The question presented was whether, under the terms of the contract between the Refining company and its customer, the leasing of containers and pumps is an "unfair method of competition" as these words are used in section 5 of the Federal Trade Commission act of Sept. 26, 1914, or whether the effect of such leasing be substantially to lessen competition and tend to create for the company a monopoly in the business of selling its products in violation of section 3 of the Clayton act.

The Court of Appeals says that neither of these sections gives the Federal Trade Commission power to regulate trade generally. And jurisdiction under section 5 exists only where there are practices that amount to a fraud in regard to some public or private right, otherwise they do not amount to an unfair method of competition. This court was of the further opinion that the company had the undoubted right to furnish any and every purchaser of its products such containers and conveniences to aid him in delivering such products into the possession of the consumer as it might see fit, and at such charges as it might see fit. The right to fix prices is not given to the Federal Trade Commission, it says, and the only cases where the question of prices has come into consideration have been those wherein the making of a price—in some cases high, in others low—has been used as an element in some fraudulent scheme of oppression. The price which one may put upon that which he has to sell or lease is a matter wholly his own.

Legitimate Weapons of Competition

Turning its discussion to competition, the court says this is not an unmixed good. "It is a battle for something that only one can get; one competitor must necessarily lose. The weapons in competition are various. Superior energy, more extensive advertising, better articles, better terms as to time of delivery, place of delivery, time of credit, interest or no interest, freights, methods of packing, lower prices, more attractive and more convenient packages, superior service and many others are and always have been considered proper weapons. Expense attending the use of any weapon, the foolishness of it, the fact that a method is uneconomical or that the competitor cannot meet any method or scheme of competition because it will be ruinous to him to do so have not, nor has either of them, ever been held unfair. Such things are a part of the strife inherent in competition."

The fact that the company loaned an expensive pump and container, more than its competitors did for the customer, does not make the transaction unfair, says the court further. If it does, then the law must mean that the Trade Commission is set as a watch on competitors, with the duty and the power to judge what is too fast a pace for some and to compel others to slow up; in other words, to destroy all competition except that which is easy.

Right of Customers to Handle Competitors' Products Not Limited

Further, this court was of opinion the company had not violated section 3 of the Clayton act. The complaint under this section against monopolizing the business is that the company made leases for the container and pump and fixed the price therefor "on the condition, understanding and agreement that the lessees thereof shall not purchase or deal in the products of a competitor or competitors of the company." But the contract showed a limitation only that the equipment should be used for the sole purpose of storing and hauling the lessor's products. There was no further agreement attempting to limit the right of customers to handle the products of competitors. Still the finding of the commission indicated the real trouble which it desired to reach to be that of leasing out costly equipment at a nominal rental far below the cost of purchasing and leasing, the effect of leasing in this manner, which smaller competitors could not meet, and by contract restricting the use of the equipment to the company's products tending to lessen competition.

Trade Commission Not Empowered to Fix Rentals

The necessary conclusion from the findings and order of the Trade Commission is, as put by the court: "First, that the commission deemed it lawful and proper for it to condemn certain rentals and also to fix and regulate the rentals on the equipment because the furnishing of such equipment required a large capital investment and because many competitors were financially unable to do that sort of thing." But the court points out that Congress did not bestow upon the commission such power.

Now section 3 does make it unlawful to make sales or leases on the condition, agreement or understanding that the lessee or purchaser thereof shall not use or deal in goods, etc., of a competitor where the effect of such lease, condition, agreement or understanding may be substantially to lessen competition, etc. But the company's contract with its customer does not prevent him from also dealing in products of its competitors; only its leased equipment shall be used exclusively in handling its own products. The court was of opinion that section 3 could not be construed as preventing the company, under the facts of this case, from putting such a limitation upon the use of the thing leased.

If anything further need be considered, the court points out that the effect of the orders of the Federal Trade Commission in this case would seem to be to terminate and destroy the contractual rights of persons (the customers) not parties to the proceeding.

The Oxidation of Ammonia—The Work of the Sheffield Experiment Station

A Study of the Fundamental Conditions Involved in the Catalytic Oxidation of Ammonia and a Résumé of the Important Unsolved Problems

By Harry A. Curtis

DURING the war the Nitrate Division of Ordnance maintained a number of experiment stations at which research on various phases of the fixed nitrogen problem was conducted. While the building of the nitrate plants absorbed the attention of most of the Nitrate Division staff, the experiment stations accumulated a considerable amount of experimental data, and but little of this has been published.

The Sheffield Experiment Station, Sheffield, Ala., of which the writer was director, was given over, for the most part, to work on the catalytic oxidation of ammonia and the production of nitric acid from the resulting oxides. During the early part of 1918 an experimental ammonia oxidation plant, having a capacity of about 500 lb. of nitric acid per day, was constructed at this station. This small plant was put in operation in May, 1918, and was run on a 24-hour basis until January, 1919. During these several months of experimenting a great deal of data was obtained. While it is not profitable to publish much of this, the results obtained in certain cases are of sufficient interest to merit permanent record.

Since, with but few exceptions, names of the men connected with the Sheffield Experiment Station are not mentioned, the writer would have it understood that the results recorded here were obtained with the hearty co-operation of all the men assigned to this work.

The Experimental Plant

The experimental ammonia oxidation plant included the following:

(*a*) A 10,000-gal. storage tank for aqua ammonia. This was set alongside a railroad spur and served from a tank car. The aqua ammonia was drawn from this tank as needed into a small blow-tank and forced by air pressure to a constant head tank at the top of the ammonia still.

(*b*) An ammonia stripping still for obtaining an air-ammonia mixture of any desired ammonia concentration. This was built of standard cast-iron flanged pipe, 12 in. diameter by 18 ft. high. Aqua ammonia was fed in at the top through a flow meter, and air from a blower was passed up through the column, the pipe being packed with coke. A little steam was blown in at the bottom to insure complete removal of the ammonia.

(*c*) A catalyst chamber about 20 in. high and 1 sq.ft. cross-section. This was built of cast iron and lined with enameled terra cotta blocks. The air-ammonia mixture entered at the top through aluminum piping, and a platinum gauze was stretched across the bottom. The platinum gauze was clamped in a nickel frame and could be removed fairly readily. This catalyst chamber or "oxidizer" was designed by Captain Perley of the Nitrate Division. It gave good service, but was rather big and heavy for its capacity. One interesting item was that this oxidizer never "howled" during operation, as many other types of oxidizers did. The oxidizer was originally designed without electrical connections, but these were later added to the apparatus and means provided for supplying electrical current up to 350 amperes.

(*d*) Coolers. The hot nitrous gases from the oxidizer were first cooled in cast-iron pipe and finally in Duriron, entering the absorbing towers at practically room temperature.

(*e*) Six stoneware towers 30 in. in diameter by 18 ft. high for absorbing the nitrogen oxides. The acid circulating system included six air-lifts made of aluminum piping and Duriron fittings.

(*f*) A chemical laboratory, office and library.

Loss of Fixed Nitrogen at the Gauze

The catalytic oxidation of ammonia on anything approaching a commercial scale was a comparatively new art in the United States when we entered the war. Two or three experimental plants had been in operation for a short time.[1] Judging from the results obtained at these small plants, it was apparent that in commercial plants, under favorable operating conditions, an oxidation efficiency in the neighborhood of 90 per cent might be expected. It was explained to the writer at that time that the remaining 10 per cent of fixed nitrogen passed through the gauze as unoxidized ammonia, and that this ammonia would eventually form ammonium nitrate, and would, therefore, be recovered in a plant where the final product was ammonium nitrate. It is now known that but little ammonium nitrate or nitrate is formed beyond the gauze, even when the oxidation efficiency is low. Further, it has been found that even if ammonium nitrate were so formed it would be decomposed in the absorption towers. These facts make several United States and foreign patents valueless.

In Table I the oxidation efficiencies obtained with several different rates of air flow are compared with the amounts of ammonium salts formed beyond the gauze. The gauze used was 12x12 in., woven 80 mesh per inch, with wire 0.003 in. diameter.

Published by permission of Chief of Ordnance, War Department.

If the average values for the ammonia oxidation efficiencies and for the percentages of ammonia converted to ammonium salts be plotted against the rates of air flow, the graphs of Fig. 1 are obtained. It will be seen that even when only 71.4 per cent of the ammonia was oxidized to nitric oxide at the gauze, but 4.4 per cent appears below the gauze as ammonium salts.

Effect of Small Percentages of Iridium in the Platinum Gauze

It was thought at one time that the platinum used in making up a platinum gauze catalyst had to be free from iridium. This was rather an important point because of the fact that it is difficult to draw fine wire of pure platinum, whereas the addition of a little iridium, even a fraction of a per cent, gives a metal much more easily handled and from which a finer wire can be drawn if desired.

A study of the oxidation efficiency of a gauze woven from an alloy of 99 per cent platinum and 1 per cent iridium at the Sheffield Experiment Station showed that the iridium had no measurable effect. The alloy for this gauze was made by the U. S. Assay Office of New York and the gauze by the Newark Wire Cloth Co. The wire was 0.0026 diameter and the mesh 80 per inch.

In Table II the average results for various rates of gas flow for a pure platinum gauze are compared with those obtained under parallel conditions with the platinum-iridium gauze, and the data are plotted in Fig. 2.

Electrical Heating of Platinum Gauze

During the construction of the nitrate plants there was considerable discussion as to whether it were possible to avoid electrical heating of the platinum gauze catalyst. The oxidation of ammonia is an exothermic reaction, and it may be calculated that the heat of the reaction, when 10 per cent of ammonia is present in the air-ammonia mix, is sufficient to raise the temperature of the gaseous products of reaction to about 800 deg. C. It was thought at one time that the optimum gauze temperature was in the neighborhood of 600 deg. C. and it was argued that but little if any additional heat was required in the gauze.

In order to study the effect of changing the temperature of the gauze when the various percentages of ammonia were being used, the following procedure was adopted: The experimental plant was operated under given conditions until it became stabilized. Samples above and below the gauze were then taken and immediately after this the electric current to the gauze was cut down so as to give a marked lowering of the gauze temperature. After a few minutes, samples were again taken. Since the plant was operating steadily the analytical results obtained from the samples represent only the temperature effect at the gauze. This procedure was repeated for several different concentrations of ammonia. The results are given in Table III and expressed graphically in Fig. 3. They show beyond question that the gauze was in every case operating below its optimum temperature, even with the high electric current consumption (about 3.3 kva.).

The temperatures which are recorded in Table III were taken with an optical pyrometer and are approximately 100 deg. lower than the actual temperatures which obtained.

When using a single flat gauze in any such apparatus as the one employed, there is little preheating of the gas mixture and the addition of heat to the gauze by electrical means is advantageous. It must also be remembered that the electric current has a very valuable stabilizing effect, for the electrical conductivity of platinum increases as the temperature is lowered, and if, for any reason, the heat supplied by the reaction itself falls off, the electric current automatically increases and keeps the gauze hot until normal conditions are again established.

TABLE III—EFFECT OF TEMPERATURE CHANGE IN A SINGLE FLAT GAUZE CATALYST

Since, however, the reaction involved is highly exothermic, it appears that a system of heat interchangers might well be employed to heat the gas mixture ahead of the gauze and so eliminate the electric heating. In 1917 the Bureau of Mines, in co-operation with the Semet-Solvay Co., designed and constructed a cylindrical gauze oxidizer[2] in which a slight degree of preheating is secured. This cylindrical gauze oxidizer was modified by Captain Perley of the Nitrate Division and installed at U. S. Nitrate Plant No. 1. Using byproduct coke-oven ammonia, the modified apparatus did not give a satisfactory efficiency. It also failed in trial runs with ammonia from cyanamide. Later, however, by installation of a heat interchanger for the air ahead of the gauze, the oxidizers at Plant No. 1 gave good results[3] on short runs. It is unfortunate that these experiments could not be continued and the new apparatus tried on cyanamide ammonia.

Ammonia Oxidation With Double Gauzes

It had been shown that the oxidation efficiency of a single flat gauze is increased by use of electrical heat in the gauze. It was also known that where no electrical heat is added, a double layer flat gauze gives a little higher efficiency per unit weight of gauze. This increase in efficiency may result both from the somewhat higher temperature at which the double layer gauze operates and to the reduction in effective gauze mesh. The idea naturally occurs to use two gauzes electrically insulated from each other, applying electrical heat only to the up-stream gauze. This idea was put into effect at the Sheffield Experiment Station in December, 1918. It was later learned that the same scheme was tried in England.

The results obtained at Sheffield were excellent, as will be seen in the data tabulated in Table IV. The two gauzes were clamped in the same nickel holder, but electrically insulated from each other by asbestos board around the edges and by some very pure asbestos fiber packed loosely between the gauzes where exposed to the gas stream. The gauzes were separated by a distance varying between $\frac{3}{8}$ in. and $\frac{1}{2}$ in. In the particular

experiment referring to the data given in Table IV, the upper gauze was of pure platinum and the lower one of an alloy of 90 per cent platinum and 10 per cent palladium, but the use of the alloy had no bearing on the experiment. Both gauzes had been activated in earlier runs.

It was then decided to try the same arrangement of gauzes, but with a base metal gauze replacing the lower down-stream platinum gauze. The purpose of this experiment was to test the idea that possibly the lower gauze, and the asbestos fiber between the gauzes, served only as a heat insulator with possibly the added effect of diminishing eddy currents in the neighborhood of the gauze. If such were the case, a base metal gauze on the down-stream side would serve as well as a platinum gauze. The results, given in Table V, are perhaps not quite conclusive, but so far as they go indicate that the beneficial results of a double gauze are due partly, but not entirely, to heat conservation and effects other than gauze activity.

Use of Ammonium Nitrate Solution in Absorption Towers

Since the use of air as an oxidizing agent for ammonia automatically sets rather a low limit to the concentration of nitric acid which can be obtained in the absorption towers, it is obvious that it would be very advantageous to circulate a fairly strong solution of ammonium nitrate in the towers, so that on subsequent neutralization of the nitric acid the excess ammonium nitrate would crystallize out. It was first demonstrated

that an ammonium nitrate solution was practically as good an absorbent for nitrogen oxides as is water. Unfortunately, however, the ammonium nitrate solution is rapidly decomposed in the towers and the whole scheme thereby rendered valueless.

Catalysis of the Reaction Between Nitric Oxide and Oxygen by Activated Carbon

One of the factors which make it necessary to provide a very large absorption system for the nitrogen oxides resulting from ammonia oxidation (or from arc process) is that the reaction between nitric oxide and oxygen to form nitrogen peroxide is relatively slow. Dr. C. L. Burdick had studied the catalytic effect of activated carbon on this reaction, working with small samples of carbon in the laboratories at Massachusetts Institute of Technology, and had obtained very promising results. In June, 1918, Dr. Burdick was assigned to the Sheffield Experiment Station, where facilities were available for trying the reaction on a semi-commercial scale.

An apparatus was set up using about 125 lb. of carbon catalyst for handling the gases from a square foot of platinum gauze oxidizer and a considerable number of tests carried out. Possibly Dr. Burdick will at some time report the details of these tests. In the present article there is space available for mention only of the general results obtained.

The first difficulty encountered with the large-scale apparatus was the discovery that with a gas containing as much as 10 per cent of nitric oxide initially, the catalyst would promptly burn up. This factor had not been disclosed by the laboratory tests. A variety of experiments were then carried out in attempting to eliminate this difficulty, but it was finally decided to put the first catalyst chamber after the first or second absorption tower, where the nitric oxide content of the gas would be lower. This proved satisfactory, but another difficulty arose in that the bed of catalyst removed so much of the fog from the gas stream that it soon became soaked with weak nitric acid solution and, of course, became inactive. This difficulty was eventually overcome by keeping the gas in the catalyst chamber well above the dew point (about 75 deg. C.) and fairly satisfactory results were finally obtained. It was found that with a total nitrogen oxide content in the gas from 1.5 to 2 per cent, under the conditions of the test, the rate of oxidation with the catalyst was, on the average, about fourteen times as great as when no catalyst was present. There is no doubt that the scheme has commercial possibilities, but there are some engineering features to be worked out in its practical application.

A Few of the Unsolved Problems Connected With the Catalytic Oxidation of Ammonia

1. *More Economical Use of Platinum Catalyst.* While platinum gauzes have been the most successful form in which platinum has been utilized as an ammonia catalyst, at least in this country, it is very likely that the present practice is not the most economical way in which platinum can be used as ammonia oxidation catalyst. The matter of wire diameter and gauze mesh has not been placed on a scientific foundation. It has been largely a case of one plant copying what has been successfully used elsewhere. At the present time, commercial practice is settled on a wire diameter somewhere in the neighborhood of 0.003 in. and a mesh of about 80. There are ample reasons for believing that this does not represent the best wire diameter and mesh. The matter of wire diameter has been somewhat fixed by the fact that it is not easy to draw pure platinum into wire finer than 0.003 in. diameter. At one time the erroneous idea prevailed that the platinum must be iridium free. This idea has been dispelled, and with the use of a little iridium in the wire it is possible to draw the platinum considerably finer. There is considerable leeway possible in the matter of gauze mesh.

Aside from the use of platinum in the form of a gauze, European investigators and possibly a few in America have tried perforated platinum foil, corrugated platinum and various other forms. None of these, so far as is known, has any advantage over the platinum gauze. It must be remembered, however, that in a gauze woven of platinum wires a considerable amount of the platinum in the interior of the wires is not active. The formation of a mossy surface on the wires very greatly increases the effective surface of the platinum, but a microscopic examination of the wires, even after they have been in use for several months, revealed a solid core of platinum in each wire which is obviously not effective in the ammonia oxidation. Numerous attempts have been made, both in this country and in Europe, to use platinum deposited on either base metal wire or on refractories such as aluminum, quartz, etc. So far as is known, none of these catalysts has been used commercially, but there is no reason to believe that success will not ultimately attend these efforts, and certainly the use of a very thin layer of platinum deposited on the surface of some refractory material which does not decompose ammonia would appear to be a better way of utilizing platinum than the ordinary gauze.

2. *Non-Platinum Catalyst.* It is well known that platinum is not the only material which will bring about the catalytic oxidation of ammonia to nitric oxide, and numerous attempts have been made to substitute cheaper materials for the costly platinum. A number of the base metals will oxidize ammonia to nitric oxide with an efficiency of, say, 70 per cent. There are also a number of oxides such as nickel, cobalt, chromium, etc., which are fairly effective in the catalytic oxidation of ammonia. The General Chemical Co. claims to have a non-platinum catalyst which operates at an efficiency of 92 per cent in an experimental plant. However, the fact remains that none of these non-platinum catalysts has been operated successfully on a commercial scale, and it is to be said of most of the experimental work that the oxidation efficiencies obtained have been hopelessly low. It must be remembered, however, that when platinum itself was first used as an ammonia oxidation catalyst, the efficiencies obtained were rather low. Even at the time the United States entered the war the oxidation efficiency actually obtained by platinum gauzes in daily use was not above 80 per cent, and there is no reason for believing that the efficiency of non-platinum catalysts could not also be increased by a further study of such catalysts.

3. *Use of Multiple Gauzes.* During the course of the experimental work carried out at this station it was shown that if two platinum gauzes be mounted in the converter at a distance of about ¼ in. from each other, but insulated from each other by a loose layer of pure asbestos fiber, there was thus obtained an ammonia oxidation apparatus which was much more efficient than

the ordinary flat gauze type. With this arrangement it was necessary to heat only the upper, or up-stream, gauze. The capacity per square foot of platinum was more than 50 per cent greater than for the platinum used in the ordinary flat gauze and, moreover, the oxidation efficiency was also raised. It was found further that if a base metal gauze were substituted for the lower platinum gauze the apparatus still had considerably greater capacity and higher oxidation efficiency than the single platinum gauze ordinarily used. The success of these experiments certainly warrants further research in the matter of using combinations of gauzes with electrical heat only on the up-stream gauze, the assumption being that the heat of the reaction is sufficient to maintain the other layers of gauze at operating temperature. It should be mentioued, of course, that with a double gauze combination, electrically heated on only one gauze, the electrical power consumption is only half as great as would ordinarily be used for the same area of platinum. There is a further possibility that a combination of platinum gauze with a non-platinum catalyst could be successfully used. For example, if the lower gauze in the above combination should be replaced by a non-platinum catalyst, it is quite possible that the non-platinum catalyst would be efficient enough to clean up any ammonia passing through the platinum gauze.

4. *Relation of the Factors: Ammonia Content of Gas, Gauze Temperature, Rate of Gas Flow Through Gauze, and Ammonia Oxidation Efficiency.* The Sheffield Experiment Station contemplated a complete study of the relation which exists between the factors listed above. However, the press of other experiments did not give sufficient time to complete the investigation. It was shown that regardless of the ammonia content of the gas, the heat developed by a single flat gauze, operated without electrical heat, is not sufficient to maintain the gauze at the optimum operating temperature. In spite of all the experimental work which has been done on ammonia oxidation by means of platinum gauze, it is the belief of the writer that the relation between the above factors has not been established on anything like a scientific basis. It is rather difficult to maintain a sufficient number of factors constant in studying the problem, and this difficulty increases somewhat in proportion to the area of the gauze used. It is thought that the problem should be attacked on a laboratory scale with a gauze measuring, say, 3x6 in. and with sufficient provision for heating the gauze electrically up to its melting point, with means for providing a very steady flow of gas and for controlling the ammonia content accurately. It is thought that the result of such experiments would throw considerable light on the actual behavior of platinum as an ammonia catalyst.

5. *Increasing the Oxygen Content of the Gas Mixture Ahead of the Gauze.* It has been frequently suggested that in place of using air and ammonia, it would be an improvement to use an air-ammonia mixture enriched with oxygen. This point is particularly well taken in view of the fact that ammonia oxidation may very likely be carried out in connection with plants where waste oxygen is available as, for example, in a cyanamide plant. There is, of course, a limit to the amount of oxygen which can be introduced because of the fact that ultimately the mixture becomes explosive. Attempts have been made to pass beyond this lower limit of explosibility by adding steam to the mixture. The obvious step would be to eliminate the nitrogen entirely and use an ammonia-oxygen mixture in the exact proportions to form either nitric oxide or nitrogen dioxide, preferably the former. The explosion which would ordinarily occur could then be damped out by means of steam, the steam being condensed beyond the gauze, leaving the pure nitric oxide, which could then be enriched with enough oxygen to form ultimately only nitric acid in the absorption towers. This would entirely avoid the dilution of the nitrogen oxides by the nitrogen and the tower losses would certainly be reduced, since this dilution by nitrogen is one of the factors which renders the absorption of the nitrous gases in the towers difficult. This scheme of using oxygen, ammonia and steam has, it is understood, been suggested in Europe and some experiments along this line have been made. Complete data are lacking.

6. *Apparatus for Continuous Analysis of Gas Mixtures.* Instruments for continuously recording the ammonia content of the air-ammonia mix passing to the catalyst and the nitric oxide content of the gas leaving the catalyst chamber would be very desirable in a plant. The ammonia analysis instrument should be fairly easy to devise.

7. *Catalysis of the Oxidation of Nitric Oxide to Nitrogen Peroxide.* The principal reason for the difficulty encountered in the absorption of nitrous gases by water is the fact that the oxidation of nitric oxide to nitrogen peroxide is a rather slow process. The absorption of nitrogen dioxide by water results eventually in the liberation of more nitric oxide. This fact results in the liberation of nitric oxide all the way through the tower system, so that obviously 100 per cent absorption is theoretically impossible, although it may be approached sufficiently near by making the absorption train large. This nitric oxide which is liberated must be oxidized again to nitrogen dioxide before it can react further with water, and obviously the slow rate of oxidation of nitric oxide to dioxide, while the gas is meanwhile being swept through the tower system, necessitates the building of a very large absorption system in order to get a reasonable recovery of the fixed nitrogen.

The use of activated carbon for catalyzing this reaction has already been described. On account of the inherent disadvantages of this carbon, however, it would be well to develop other catalysts.

Iron Ore Production in France

During the year 1921 14,106,068 metric tons of iron ore was mined in France, as compared with 13,846,122 metric tons in 1920, an increase of 259,946 metric tons, or 1.8 per cent. In 1913 French iron ore production amounted to 21,917,870 metric tons, to which amount should be added 21,136,265 metric tons produced in the Metz-Thionville basin, which was German at the time. The 1921 output represents only about one-third of the production realized in 1913 within the present boundaries of France.

Statistics of production show a noticeable decrease in the monthly tonnage per man. Previous to the war the monthly production of a French miner was 71.6 metric tons in 1920, an increase of 259,946 metric tons. In 1913 the German miner in the Metz-Thionville basin was credited with a monthly average of 109.7 tons.

Metallic Tantalum Now Commercially Available

AS A RESULT of research extending over a period of 6 years, the Fansteel Products Co. of North Chicago, Ill., has developed a process for the production of metallic tantalum. It was felt that certain characteristic properties of this element—particularly the combination of its softness and workability with its extreme resistance to wet corrosion—would make it a valuable material in American technology. The following information regarding this interesting new commercial metal will supplement the brief reference made in *Chem. & Met.* for June 14, 1922, p. 1141.

No tonnage uses of the material can ever be expected, as it must be manufactured in an atmosphere free from oxygen, hydrogen, nitrogen and other common gases. It is, as a matter of fact, made *in vacuo*, which, of course, will make its price excessive for use as an ordinary metal.

Resistance to Wet Corrosion

Its resistance to wet corrosion is its most obvious characteristic. It is unattacked by any acid or alkali solution even at boiling temperatures, excepting hydrofluoric acid and its mixtures with other acids. It is unattacked by aqua regia.

Electrically also it has some interesting properties, the most novel of which is its valve action in electrolytic cells, a property which it holds in common with aluminum. A dielectric oxide is readily formed on its surface, which makes it useless as an anode in electrolysis, as no direct current will pass. This property, however, permits its use in electrolytic rectifiers for alternating current, where it has the apparent advantage over aluminum of its extreme chemical resistivity, which permits a wide choice of electrolytes.

Combines With Gases at High Temperatures

Its high melting point, about 2,850 deg. C., is of no commercial advantage, except where the atmosphere may be made to exclude the gases which will combine readily with it. In its combination with gases at elevated temperatures it forms stable compounds which are not readily dissociated into the gas and pure metal below the melting point. No very close study of its action in gases has been made and it is impossible to say at the present time if it is selective in its action or whether it continues to take up gas at all temperatures to its melting point, or whether it will release certain gases at high temperatures *in vacuo*.

Tantalum has not been available in the United States since 1914, when the German source was cut off. The possibilities of its utility will now be very much greater than they were in 1914, as the various electrical arts, particularly those requiring high melting point materials and use *in vacuo*, have been very largely developed since that date.

Properties to Be Studied Fully

No very reliable list of all of the properties of tantalum has been compiled to the present writing, but steps are being taken to make a complete scientific investigation of the properties of the pure material.

All of the work in the development of a commercial process for the manufacture of pure American tantalum has been done for the Fansteel company by Dr. Clarence W. Balke, the company's research director. Dr. Balke has always been interested in tantalum and its sister metal columbium, since he determined the atomic weights of these materials, working under Dr. Edgar F. Smith at the University of Pennsylvania. These determinations, made about 10 years ago, are still accepted in the international table of atomic weights.

Work on Columbium Under Way

Further research work is being conducted by the Fansteel company on columbium with a view to determining what commercial advantages this material may have.

The sources of raw material occur in the United States chiefly in the form of columbite, although a certain amount of tantalite is available. Hitherto stocks of the material have come from Australia, where excellent grades of ore are still obtainable.

Volatilization of Copper at Low Temperatures

In a recent research on decarbonization of steels[1] a piece of medium-carbon steel was fixed to a copper support by a pure iron wire and heated for 4 days in a stream of dry hydrogen at about 800 deg. C. When the furnace was opened, the steel was tightly welded to the copper, and everything was covered with a bright copper plate. A microscopic view showing the wire binding is shown in Fig. 1. Evidently the iron wire

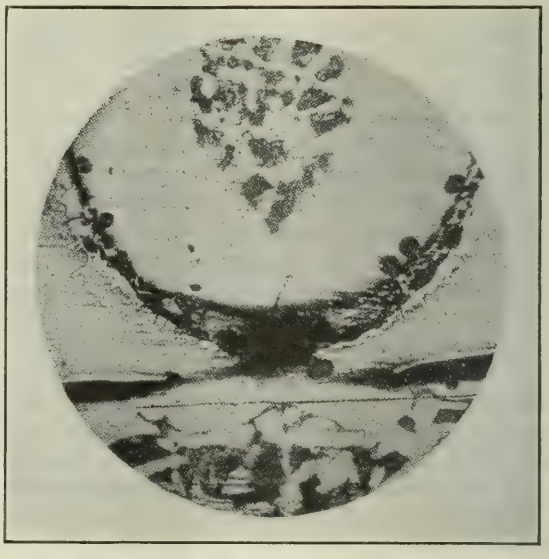

FIG. 1—MIGRATION OF CARBON AND COPPER IN HYDROGEN AT 800 DEG. C. (× 100)

had first been carbonized throughout to approximately the carbon content of the steel sample, whereupon the decarbonization of both steel and its fixture ensued. Meanwhile a thin film of copper had deposited (vaporized from the copper support) and alloyed, the alloy later being covered by a layer of substantially pure copper.

Small Cottrell Precipitator

The Research Corporation has designed a new so-called "BL" unit type of precipitator, applicable to dust recovery. It is lighter, smaller, more compact and simpler to install than the old type, and is available in capacities up to 25,000 cu.ft. per minute. It is shipped ready to set up.

Synopsis of Recent Chemical & Metallurgical Literature

Surface-Coated, Photographic, Cigarette and Miscellaneous Papers

The United States Tariff Commission has just issued a report entitled "Surface-Coated, Photographic, Cigarette and Miscellaneous Papers." This report is one of a series to be published by the commission dealing with different kinds of paper. In structure it follows the general outline of all the tariff information surveys prepared by the commission, the aim of which is to present to Congress in detail sifted data that may serve as a guide in framing scientific tariff legislation. These data relate to description of the different varieties of paper, raw materials used, processes of manufacture, volume and value of production, imports, exports, prices, tariff history, nature of competition with foreign countries, customs decisions, etc. The papers considered are surface-coated, waxed, gummed, decalcomania and decorated paper; cloth-lined or reinforced paper; photographic and blueprint paper; cigarette paper; papier-mâché; paper not specially provided for in the tariff law; miscellaneous manufactures of paper, such as bags and boxes; and paper stock.

Electrodeposition of Iron

A 50-page bulletin has been written for the British Department of Scientific and Industrial Research on "Electrodeposition of Iron," by W. E. Hughes[1]. In it he describes eight different types of deposits—viz., normal, columnar, mosaic, poplar-tree, fibrous, fan, cauliflower and fountain. Most of these names are self-descriptive and applicable to various electrodeposited metals. Normal deposit is most frequent; in it many prominent grains have a V shape, pointed inward toward the cathode.

Using a current density of 120 amp. per sq.ft., a 2½-gal. bath of neutral ferrous chloride[2], depositing for 2 hours on a cleaned copper rod, the effect of varying temperature from 70 to 116 deg. C. is as follows: As temperature increases the surface becomes rougher and the grain becomes coarser, the deposit softer and less brittle. (It is a quite general rule that the more coarsely crystalline the surface is the larger the grain size of the metallic deposit.)

Maintaining the temperature at 110 deg. C. and varying the current density from 60 to 240 amp. per sq.ft. gave results indicating that a maximum grain size is reached at about 120 amp. per sq.ft. and a minimum exists at about 200. Heavier densities again coarsen the grain. As before, coarse grain is associated with softness and lack of brittleness; the metal can be safely hammered while cold.

A great and striking difference exists between two deposits made under like conditions except that one contains a rotating cathode. The latter surface is extremely smooth and the metal is very much finer in grain, often approaching a fibrous structure when sectioned and examined under the microscope. It is also characteristically hard and brittle.

Adhesion of the deposit depends upon absolute cleanliness of the cathode. This involves boiling in an alkaline cleanser, treatment by an electro-cleaner, and dipping in 10 per cent HCl, with appropriate scrubbing and rinsing between.

A small quantity of free acid will generally cause an iron deposit to be fine grained to fibrous, even if made at low current density. Furthermore, the solutions must not become materially depleted in iron content if thick, uniform deposits are desired.

[2] Concentration not noted; possibly Merck's solution (100 kg. $FeCl_2$ to 100 liters water.)

Use of Rubber in Paper Making

Engineering, London, for Sept. 8, 1922, comments editorially on the interest which is being taken in the research work of S. Kaye on the addition of rubber latex to paper stock during the beating operation for the purpose of improving the strength and quality of the paper. Representatives both of the rubber industry and the paper manufacturers were present at a recent meeting of the Rubber Institution, when Mr. Kaye read a paper entitled "Rubber Latex in Paper Making." The amount of rubber which actually enters into the constitution of the paper is very small indeed, but in some unexplained way the addition of the latex appears to assist the hydration of the cellulose fibers, with a consequent reduction in the time required for beating and the power consumed.

The article emphasizes a point brought out during the discussion by a speaker who suggested that since the beneficial effect of the rubber is not due to its rubbery nature but to the colloidal properties of the latex, further investigation might disclose some more easily procurable colloid which would have the same effect. This, of course, is merely speculation, as the mechanism of the acceleration of the hydration of the fiber by the latex is not understood. Several possible developments of the process were indicated at the meeting, such as the production of waterproof containers for packing liquid and semi-liquid substances. The dyeing of rubber-treated paper has not been found difficult, even when the rubber content amounted to as much as 30 per cent. Rubber-treated paper bears up well under rigid tests for durability. It was also suggested that where a rubber content of 5 per cent or more was used, it might be found advantageous to vulcanize it, as the paper would be rendered stiffer and stronger.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Cellulose Ester Solvent — Carbon tetrachloride as a solvent for cellulose ethers for film base is covered by a patent assigned to the Eastman Kodak Co. by William R. Wibb, of Rochester, N. Y. It is claimed that a solution of the proper viscosity for casting may be obtained by using a mixture of tetrachloride and ethyl alcohol. The specification covers solvent mixtures ranging from 5 to 95 parts of carbon tetrachloride and 95 to 5 parts by weight of ethyl alcohol, although the ratio 60:40 tetrachloride:alcohol is mentioned specifically. (1,418,413. June 6, 1922.)

Greaseproof Paper—The use of sugar as a coating for paper containers to render them greaseproof is covered by a patent taken out by Wilbur L. Wright, of Fulton, N. Y., and assigned to the Sealright Co. The idea is based on the fact that various compounds included under the general term sugar are harmless commercial products, cheap and not appreciably soluble in oils and other greases, particularly food products, and that hence if paper can be coated with an unbroken or impervious coating of sugar, or if the fibers and body of the paper can be completely filled or impregnated with sugar, this treatment will constitute a barrier against the passage of grease. Gelatine is used as a medium for the sugar, and a hygroscopic ingredient such as glycerine and a hardener, such as alum, are also added to the treating solution. It is claimed that paper covered with this material dries quickly, producing a bright smooth surface that is hard and not sticky, that is flexible and more or less elastic, is tasteless, odorless, colorless, and does not cause harmful action in food products put up in such packages. (1,417,708. May 30, 1922.)

Naval Stores—An apparatus for the extraction of turpentine and rosin from pine stumps is covered by a patent taken out by Jerry M. Jordan, of Crestview, Fla. The apparatus is merely a closed retort surrounded by a water jacket. A firebox is provided which boils the water in the jacket and keeps the retort surrounded by steam. The inventor claims that it is possible by the use of this apparatus to obtain turpentine from waste pieces of wood, slashings, dead wood, etc., and that a large amount of turpentine can be obtained cheaply from tracts of timber where the turpentine has been extracted in the usual fashion and which would otherwise be worthless. (1,424,248. Aug. 1, 1922.)

The Vulcanization of Rubber—Paranitroso-di-methyl-aniline is a poison

and because of this fact its properties of accelerating the vulcanization of rubber are not extensively used. Bedford and Sibley, of Akron, Ohio, have discovered that this compound will react in an organic solvent with hydrogen sulphide to produce a substance with strong basic properties. This substance has the same accelerator effect on rubber that paranitroso-di-methylaniline has. It is quite odorless and can be stored for a long period of time without danger of poisoning those in the vicinity. (U. S. Pat. 1,418,771.)

Available Potash From Leucitic Rock—Dr. Blanc and N. Felix Gourdan, of Rome and Paris respectively, have taken out a patent to render the potash in leucitic rock available at considerably less cost than the present process. At present, it is necessary to grind the rocks and treat them with strong mineral acids such as hydrochloric acid, but when large quantities of material are employed, the process becomes extremely expensive. The potash in leucitic rock is combined in such a way as to be rather readily separated from its silicic acid component. By grinding the rock to an impalpable powder, the authors declare that not only strong acid but weak mineral acid and even organic acid will attack the potash and make it soluble. It is actually accomplished by means of carbonic acid (CO_2). The potassium carbonate thus formed can be readily washed from the insoluble material, or the leucitic rock can even be used as a fertilizer ingredient directly without lixiviation. In order to accomplish more easily the breaking up of the leucite, the rock is first calcined in the presence of steam or with quicklime magnesia, etc. The calcined material is then introduced after grinding into the treating apparatus. It is extremely interesting that fine grinding has made weak acid effective in breaking down the leucitic rock. (U. S. Pat. 1,418,356.)

Method of Purifying Carbon—Victor Lenher, of Madison, Wis., and Frank M. Dorsey, of Cleveland, Ohio, are the coauthors of this extremely interesting patent. A much more porous and much purer charcoal is obtained by this process than is possible by a simple activation. The activation process, of course, consists in heating charcoal in the presence of superheated steam to from 700 to 1,100 deg. C. This produces a porous structure, but is not nearly as desirable an article as the product which is prepared by this new method.

The carbon first is heated with selenium oxychloride. Selenium oxychloride at room temperature or as high as 50 to 100 deg. C. is first used and this dissolves many of the impurities and forms a very porous structure of very pure carbon. The selenium oxychloride must be removed, however, and this is accomplished with either carbon tetrachloride or chloroform. (In fact, it is found desirable to dilute the selenium oxychloride in the first place with about 25 per cent of carbon tetrachloride.) The residue of carbon tetrachloride is then distilled out of the carbon and recovered. (1,423,231; assigned to the General Electric Co., New York. July 18, 1922.)

Rubber Accelerator — Benjamin D. Porritt, of Edinburgh, has taken out a patent for the use of monohydroxy nuclear substances, such as phenol or its analogs. In other words, he takes about 2 per cent sodium phenate with ninety parts of rubber and ten parts of sulphur. This addition reduces the vulcanization time more than 75 per cent. (U. S. Pat. 1,418,166.)

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Tanning—Hides and skins are tanned by means of soluble magnesium salts and soluble carbonic acid salts of other bases in the presence of water. A mixture of the dry salts may be introduced into a drum containing the wet hides, the moisture being sufficient to dissolve the salts and render them active, or the hides or skins may be drummed successively in separate solutions of the salts. The process may be applied to partly tanned hides, or may be combined with other processes such as tanning or treatment by cellulose sulphite liquors, formaldehyde, chrome, iron or other mineral tanning agents, or vegetable tanning agents, used in admixture or separately. In an example, 100 kg. of unhaired hides is drummed for 4 to 6 hours or longer in a concentrated solution containing 21 to 22 kg. of magnesium sulphate and 7 kg. of sodium bicarbonate or 9 kg. of sodium carbonate, or the hides may be first drummed in a solution of one of the salts, the other salt being added subsequently. This treatment may be followed by rinsing and oiling or by treatment with fat, grease, etc., to which formaldehyde has been added, or the hides may be pressed out or exposed to the air, then coated or brushed over with cellulose sulphite liquor and afterwards rolled and greased. Alternatively the cellulose extract may be aded to the tanning mixture. Formaldehyde, chrome alum or salts of iron, zinc or barium or small quantities of vegetable tanning materials such as oak extract may be added to the tanning mixture described in the example or may be employed in separate solutions for subsequent treatment. In a further example the hides, after treatment with the mixed salts and formaldehyde, are steeped in milk of lime and then further treated as in the first example. The various processes are stated to produce heat-resisting qualities, durable graining or embossing, etc., firm or soft texture as required. (Br. Pat. 180,758; J. Hell, Wurttemberg. July 26, 1922.)

Lead Chromate Pigment—Lead chromate for use as a pigment is obtained by treating lead sulphate, preferably freshly precipitated, with an equivalent quantity of a soluble normal chromate such as sodium or ammonium chromate. Paler yellow pigments are obtained by using smaller quantities of the soluble chromate, products of the composition $PbCrO_4.PbSO_4$ and $PbCrO_4.2PbSO_4$ being mentioned. (Br. Pat. 182,693. H. Hetherington and W. A. Allsebrook, Matlock Bath, Derbyshire. Aug. 30, 1922.)

Bleaching—Loose cotton and cotton yarns or fabrics, etc., are bleached by first treating the goods with a soda lye containing soluble hydrosulphites, preferably in a vacuum at temperatures below 100 deg. C., and then bleaching by means of other bleaching agents, such as hypochlorites, hydrogen peroxide, perborates, percarbonates, persulphates, etc. Sodium or ammonium hydrosulphites may be used, and the goods may be scoured and washed during the bleaching process. (Br. Pat. 182,776; not yet accepted. C. Bochter, Günzburg. Aug. 30, 1922.)

Ethers and Esters—Ethers and esters of ethylideneglycol and vinyl alcohol are produced by passing acetylene together with the vapor of compounds containing hydroxyl or carboxyl groups over heated catalysts, especially metals, their oxides and salts. Examples of suitable catalysts are cadmium, zinc, mercury, magnesium, barium, copper, silver, cerium, nickel and iron, or their compounds, preferably mounted on a support such as charcoal, pumice or infusorial earth. The reaction may be carried out under increased or reduced pressure; and is preferably conducted as a cyclic process, the unchanged hydroxyl or carboxyl compound being continuously separated from the product and returned with fresh acetylene into the reaction chamber. According to the example, equal volumes of acetylene and acetic acid are passed at a temperature of 200 deg. C. over charcoal inpregnated with cadmium acetate; ethylidene diacetate is isolated from the condensed product. (Br. Pat. 182,112; not yet accepted. Consortium für Elektrochemische Industrie Ges., Munich. Aug. 23, 1922.)

Cyanamide Residues — The residues resulting from the decomposition of calcium cyanide by acids to obtain assimilable nitrogen compounds are converted into industrial products such as nitrogenous manures, lime and carbon dioxide. If carbon dioxide or sulphur dioxide is employed as the acid, the residues contain calcium carbonate or sulphite carbon and impurities. According to one process they are air-dried and mixed with solutions of urea, urea salts or any assimilable nitrogenous compounds obtained from calcium cyanamide. In an example the residue from the carbon dioxide process is air-dried and mixed with a solution of urea sulphate and the whole evaporated to obtain a manure. The residue from the carbon dioxide process may also be employed instead of a mixture of limestone and coke to obtain quicklime and carbon dioxide. In this case the air-dried residue is either calcined directly or briquetted and calcined. Additional oxygen may be introduced into the furnace. (Br. Pat. 182,134; not yet accepted. Soc. d'Etudes Chimiques pour l'Industrie, Geneva. Aug. 23, 1922.)

Titanium Catalyst for Hydrocarbons—Aromatic hydrocarbons are oxidized by passing their vapor admixed with air or oxygen over a catalyst consisting of or containing titanium compounds—for example, titanium oxide or brick rich in titanium. The presence of nitrogen oxides assists the oxidation; steam or other inert gas may also be added. The catalyst may be supported on a carrier, such as brick, asbestos or pumice. Examples are given of the oxidation of anthracene to anthraquinone and of naphthalene to phthalic acid and phthalic anhydride. (Br. Pat. 182,843, F. W. Atack, of British Alizarine Co. Ltd., Manchester. Sept. 6, 1922.)

Book Reviews

RAYS OF POSITIVE ELECTRICITY AND THEIR APPLICATION TO CHEMICAL ANALYSES. Second Edition. By *Sir J. J. Thomson, O.M., F.R.S.*, 237 pp. New York: Longmans, Green & Co. Price $5.25 net.

The appearance of the second edition of this well-known monograph in the series of monographs on physics, of which the author is the editor together with Prof. Frank Horton, will be welcomed by a wide circle of readers. The second edition contains much new material, the size of the first edition having been doubled. Besides the value it possesses for physicists and those especially engaged in the problem of the conduction of electricity through gases, it presents a particular interest for chemists through its direct bearing on the constitution of atoms, molecules and gaseous ions.

The author states in the preface to the new edition: "I have paid special attention to those properties of the positive rays which seem to throw light on the problem of the structure of molecules and atoms and the question of chemical combination. The hope expressed in the first edition that the method of positive rays would be of service in connection with important chemical problems has been fulfilled to a remarkable extent by the researches of Mr. Aston and others on the determination of atomic weights and the detection of isotopes. I am convinced that as yet we are only at the beginning of a harvest of results which will elucidate the process of chemical combination, and thus bridge over the most serious gap which at present exists between physics and chemistry."

Besides a full discussion of theory and descriptions of experimental details, including Aston's focus method and Dempster's method, the text is replete with a judicious weighing of evidence for and against the assumption of the existence of isotopes. The author makes it very clear that he has maintained an open mind on this subject and that he does not accept as final the proofs hitherto adduced which have appeared conclusive under a less searching analysis. The possibility that the isotopes of neighboring atomic weights may prove to be hydrides of the ordinary atoms is given the most careful consideration. While there is strong evidence against this assumption, the author does not dismiss it without a thorough examination.

The concluding pages are devoted to the opportunities of future application of positive rays in studying molecules and the mechanism of their structure, and strong recommendation is made for the method as a means of spectroscopic analysis much simpler and more definite than ordinary spectroscopy. The field is one which should not be neglected in experimental chemistry, and, as the author points out, involves, in its simpler applications, neither a complicated apparatus nor a difficult technique.

S. C. LIND.

ORGANIC CHEMISTRY, OR CHEMISTRY OF THE CARBON COMPOUNDS. By *Victor von Richter.* Vol. II, Chemistry of the Carbocyclic Compounds, edited by Prof. R. Anschütz and Dr. H. Meerwein. Translated from the eleventh German edition by E. E. Fournier D'Albe, D.Sc., A.R.C.Sc. xvi + 760 pp. Philadelphia: P. Blakiston's Son & Co. Price $8.

Richter's Organic Chemistry needs no introduction to organic chemists. To others mention of the fact that it has passed through eleven German and three American editions is sufficient introduction. Richter's text has been enlarged so much in order to make it complete that it is now a compendium—a sort of abridged Beilstein—rather than a class text. This fact does not, however, detract from its usefulness in advanced classes, especially for certain topics—for example, the terpenes—and as a handy reference book.

The eleventh German edition was published 10 years ago and therefore some of the very recent developments are not included in the volume under review. Yet the book contains an abundance of material which is well classified, well described and well illustrated with examples. This second volume is a good translation of the major portion of the German second volume. It treats of the following subjects: cyclo-paraffins, cyclo-olefines, general aromatic chemistry—benzene, its homologs and their numerous derivatives, hydro-aromatic compounds, terpenes, naphthalenes, anthracenes, etc., glucosides, bitter principles, and natural dyes, the last three only very briefly. The part covering the heterocycles is omitted and probably will appear as a third volume. Some idea of the number of compounds discussed in the present volume may be obtained when it is mentioned that the index covers thirty-one full pages, two columns to the page and seventy-five lines to the column.

The translation is clear and generally accurate, and the arrangement of the work is admirable. The typography is excellent, better than in the first volume. The name of each compound when first described is emphasized by being printed in bold-faced type.

A somewhat careful reading of a goodly portion of the text brings out a few errors and raises some questions which require comment. In the spelling of names and radicals the translator is not always consistent or correct according to the best usage. "Benzene" and "benzol" sometimes alternate in the same sentence or paragraph, and the homologs of benzene, except mesitylene, are given the suffix "ol" instead of "ene." The obsolete term "amido" is found here and there in place of "amino" (pp. 382, 406), and "amine" as a name and the names of amines such as toluidine in a few instances have no final "e." This spelling shows a direct transcription of the name rather than a tendency to shorten the ending. Similarly with naphthalene and some of its derivatives, which are frequently given the less used ending "in." The translation of "Benzolkohlenwasserstoffe" in the heading (p. 49) as "Benzene Carbohydrates" instead of "Benzene Hydrocarbons" is unfortunate. It oftens seems that the translator is endeavoring to vary the names or their spelling in order to avoid monotony but, commendable as this practice is, clearness and accuracy may be sacrificed by so doing. He naturally uses the English spelling in such words as "oxidised," "colour," etc., although the book is printed in Philadelphia. "Nitrogenation" (62), "nitrogenated" (67), "nitrifying" (107, 170, 416) and "nitrified" (445) are neither correct nor advantageous terms for nitration, nitrated, etc., which are properly used in many other places. The reviewer believes that if another word is to be substituted for nitration where the introduction of a nitro group is meant, "nitronation" would be more satisfactory, since it is definite and corresponds to the term sulphonation in the type of reaction as well as the name. The terms "rejection" (95, 106, 108, 116, 208) and "discarding" (448) used in connection with water, carbon dioxide, etc., do not carry the meaning conveyed by "elimination" or "separation," and certainly are not in good usage, nor is "acetyling" (166) for acetylation, and "water vapor" for steam. Translation of the German plurals as "phenolene" (61) for "phenols," and "alkylene" (116) for "alkyls" is very puzzling at first. A number of structural formulas have a dot or line missing. The formula for heptachloro-resorcin (460) is incorrect in both original and translation, several formulas mentioned in the text on p. 514 have been left out, and there is a mix-up in the translation referring to 1,4-anthraquinone (705). The typographical errors are really few in such a difficult piece of work.

The comments given above are not meant in the least to detract from the real service which the translator and publishers have rendered in giving English-speaking chemists this standard and important work in their own language.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Fine Chemical Manufacturers Will Appeal for Tariff Rate Changes

Will File Applications Under Flexible Tariff Provisions—No Difficulties in Administering New Rates

PRESSURE already is being brought by those interested in the synthetic organic chemicals not of coal-tar origin to have early hearings before the Tariff Commission with a view toward securing an increased rate on many of the chemicals embraced in paragraph 5 of the tariff act. The manufacturers of these chemicals believe the rate provided in the new law is entirely inadequate, particularly for the fine chemicals of high value. This also applies to the medicinals.

Regulations under which applications for changes in tariff rates may be filed under the flexible tariff section of the new act are expected to be issued by the Tariff Commission about Oct. 11. A committee of the commission is conferring with its legal department regarding the rules and the methods of procedure. Precedents established by the Federal Trade Commission and the Interstate Commerce Commission for complaints and hearings are being studied in this connection.

Provisions for Rate Changes

Under the Fordney-McCumber tariff act, applications for a change in rates may be filed either with the President or with the Tariff Commission. If filed with the former, they will be referred to the commission for investigation and report. The commission shall report its findings to the President, who thereupon may increase or decrease a rate within a range of 50 per cent. If an increase of 50 per cent be insufficient to equalize the cost of product here and its cost abroad, an ad valorem duty may be transferred to the basis of American valuation, but in this event the figure cannot be changed. A specific rate may not be changed to an ad valorem, nor an ad valorem to a specific. The duty on coal-tar products, placed on American valuation in the act, cannot be increased under this clause.

The Tariff Commission probably will open an office in New York City to conduct some of the hearings and gather the samples and data required of it under the new law, according to announcement of Chairman T. O. Marvin.

Although hard pressed by work, owing to an inadequate force, the customs division of the Treasury Department has encountered no serious difficulty in administering the new tariff, and, according to Ernest W. Camp, chief of the division, none is expected of an extraordinary nature.

In administering the rates on imports of coal-tar products, which were placed on American valuation in the new tariff, the customs service has taken over the files and records of the Dye and Chemical Control Board, which automatically went out of existance with the effective date of the new tariff which ended the licensing system or so-called embargo. The board had many samples and data which were necessary under the licensing system and which have proved useful in handling the tariff.

No Difficulty Expected

"We do not expect any great difficulty in administering these coal-tar products rates," said Mr. Camp. "If there is a doubt, we will assess the highest rate that might apply in the case, as provided by the tariff act and as was the law under the old tariff, and an appeal may be had.

"The appeals board may be kept busy, and final liquidations may get congested, but it may be expected that very rapidly there will be established sufficient precedents to remove further difficulties."

Customs Personnel Insufficient

The customs division officials expect to work out new regulations as rapidly as cases are called to their attention. Meanwhile, collectors who appeal to headquarters for rulings are being given instructions to admit imports under bonds which will fully protect the revenues pending final liquidation. Thus there will be no delay in getting goods to consignees who are willing to supply bond and await adjudication of their cases.

The most serious handicap in administering the customs is said to be insufficient personnel. This is not a new complaint, but it has been aggravated by change in tariff duties. When the war came and imports decreased heavily, the customs force was reduced from 8,200 to about 6,700. No increase was made when the emergency tariff was imposed in 1921, affecting many imports, and none has been provided for the new tariff. Heavy foreign travel has been delaying ordinary work at some ports because of the necessity of switching inspectors from cargo work and appraisers' warehouses to the inspection of personal baggage.

Representatives of the manufacturing chemical industry have assured Secretary of Commerce Hoover that their flag has been nailed to the mast and that they will continue to do an export business.

Salesmen's Association Discusses Exposition Plans

To Investigate Claims of Rival Enterprises and Support Management Offering Best Service

A meeting of the executive committee of the Salesmen's Association of the American Chemical Industry was held at the Chemists' Club, New York City, Monday evening, Sept. 25. Those present were: President, John W. Boyer, Williams Haynes, Fred J. Signer, Ray P. Dunning, R. E. Dorland, Walter Goff, J. D. Lowery, F. P. Summers, David Stewart and George T. Short, secretary.

Reply to invitation from Adriaan Nagelvoort, manager of the new co-operative chemical show, was the appointment of a committee to investigate claims of the rival show managements and to report back to the association with recommendations. The sentiment of the meeting was that one show was essential to success and that the exhibits, being in charge of the sales departments of the chemical manufacturers, the Salesmen's Association could render constructive service to the whole industry by sifting the rival claims and throwing weight of their support with the management offering best service to American chemical makers.

F. P. Summers, of the Noil Chemical Co., was named chairman of the membership committee.

Salesmen's Study Course

F. E. Breithut, of the College of the City of New York, outlined a plan for a short night course for chemical salesmen and offered college co-operation in giving such a series of lectures under the auspices of Salesmen's Association. His invitation to hold the next meeting up in the tower of the college was accepted and the date set for Friday Oct. 13. This will be the annual meeting of the New York chapter, at which new local officers will be elected.

Doubt Report That German Dyes Will Pay Bill of Army on Rhine

State Department Did Not Authorize Statement That 5 Per Cent of German Output Will Be Accepted Without Cash Payment

PUBLICATION in the daily press of an article to the effect that the Secretary of State has worked out a plan whereby the cost of maintaining the American army of occupation on the Rhine would be met in part by turning over to the United States its proportion of the reparation dyes without money payment has caused great uneasiness within the dye industry, as is attested by the large number of telegrams which have been received by officials concerned. At the State Department it was asserted positively that no such information had been given out, but Secretary Hughes declined to confirm or deny the statements made in the article.

Dye specialists in Washington are inclined to doubt that any such plan is in contemplation.

The story, which was given some prominence in the daily press last week, stated that Secretary Hughes, after consultation with allied governments, had agreed to permit the United States to receive its share of German dyes without money payment, as has been the practice heretofore, the cost of these dyes to be credited on the American bill against Germany for the army of occupation.

History of Reparation Dyes

During the peace conference in Paris there were subsidiary negotiations between the United States and the Allies on the one hand and Germany on the other relative to the exceedingly complicated question of German dyes. These negotiations, extending over a considerable period, were held at Spa and it was agreed that 25 per cent of the total German dye output should be delivered to the Allies on account of reparations. The United States was to receive one-fifth of this, or 5 per cent of the total German output, but since the United States sought no reparations from Germany it was stipulated that this government should pay cash for any dyes received at market prices.

Later, when the question of payment of the United States for the maintenance of its army of occupation on the Rhine arose, Secretary Hughes made it plain that the United States did not propose to be left out in the cold by any arrangement by the Reparation Commission that would interfere with payment by Germany of the cost of the maintenance of the American forces on the Rhine. The justice of the American contention could not be denied and the Reparation Commission finally announced that the matter had been referred to the allied governments for consideration, note being taken by the commission of the American objection to payment of general reparations in advance of a settlement of the costs of maintaining the American army of occupation.

Method of Distribution

Before the ratification of the treaty of peace between the United States and Germany the understanding regarding German dyes had not received a clear legal status. The Textile Alliance had been organized for the distribution of German dyes in the United States. The American treaty with Germany, however, specifically guarantees the rights of the United States with respect to the reception of German dyes, and the same treaty further makes it possible for Congress to create a mechanism for handling such dyes whenever received in the United States.

Customs officials state that, unless Congress specifically directs otherwise, dyes imported under such a plan would pay duties charged under the new tariff bill.

Pottery Firms Indicted for Price Fixing

Twenty-Three Companies Charged With Conspiracy to Fix Prices and Stifle Competition

Conspiring in price fixing and unlawful restriction of sales are the two counts charged in an indictment against twenty-three companies, representing 85 per cent of the pottery industry of the United States, and twenty-four men, officers of the same companies.

This indictment is the last of the series resulting from the housing investigation of the Lockwood committee, authorized by the New York State Legislature. It was returned by the July Federal Grand Jury, but on motion of Colonel Hayward, United States Attorney for the Southern District of New York, was held under seal pending further investigation.

Charges Price Fixing

The indictment charges specifically that the defendants engaged in a price-fixing combination whereby they refrained from competing with one another on a price basis, thus exacting "uniform, arbitrary and non-competitive prices."

The second charge, as explained by Colonel Hayward, involves a practice whereby the defendants were barred, by common consent, from selling their products directly to builders, architects or contractors. All sales, it is alleged, had to be made through so-called "legitimate jobbers." In this manner, according to the District Attorney, prices to the consumer were increased "beyond all reasonable proportions."

Stifled Competition

After adding a profit, the charge continues, the jobber would confine his sales to a so-called legitimate plumber, who would add his profit. After that it would go to the contractor. Each group by this plan, according to charges, was placed in a position to dictate prices and profits without fear of competition.

It is understood that the defendants will be called for pleading within 2 weeks and will be brought to trial soon. The individuals indicted and the companies they represent are as follows:

James E. Slater, president and manager of the Abingdon Sanitary Manufacturing Co., Abingdon, Ill.

James A. Dorety, Jr., secretary of the Acme Sanitary Pottery Co., Trenton, N. J.

Bart O. Tilden, president of the B. O. T. Manufacturing Co., Trenton, N. J.

John W. Bowers, president of the Bowers Pottery Co., Nannington, W. Va.

T. Munro Dobbins, president and treasurer of the Camden Pottery Co., Camden, N. J.

Theodore H. Sharker, secretary and treasurer of the Chicago Pottery Co., Chicago, Ill.

Walter F. Drugan, vice-president of Cochran-Drugan & Co., Trenton, N. J.

Raymond E. Crane, vice-president of the Eljer Co., Cameron, W. Va., and Ford City, Pa.

Edward V. Brigham, vice-president and general manager of the Kalamazoo Sanitary Manufacturing Co., Kalamazoo, Mich.

G. E. Rhodes, general manager of the Kokomo Sanitary Pottery Co., Kokomo, Ind.

Harry J. Lyons, president and treasurer of the Keystone Pottery Co., Trenton, N. J.

Philip J. Faherty, treasurer of the Lambertville Pottery Co., Lambertville, N. J.

William B. Maddock, secretary of John Maddock & Sons, Trenton, N. J.

Archibald M. Maddock, president of Thomas Maddock Sons Co., Trenton, N. J.

Harry F. Weaver, secretary and general manager of the National-Helfrich Potteries Co., Evansville, Ind.

Newton W. Stern, president of the Pacific Sanitary Manufacturing Co., Richmond, Calif.

John F. Smith, treasurer of the Resolute Pottery Co., Trenton, N. J.

(*Continued on page* 713)

Stansfield to Address Cleveland Iron and Steel Engineers

Prof. Alfred Stansfield, well-known authority on the electric furnace, will be the speaker at the Oct. 9 meeting of the Cleveland District Section of the Association of Iron and Steel Electrical Engineers. Dr. Stansfield has taken as his subject "Electric Smelting of Iron Ores" and will illustrate his remarks with lantern slides. The meeting will be preceded by a dinner at the Cleveland Engineering Society's club rooms at the Hotel Winton.

Muscle Shoals Disposal Will Be Revived

Scheduled for Consideration After Recess—Big Power Demand in District

Advocates of acceptance of the Henry Ford offer for the Muscle Shoals project caucused before Congress adjourned and laid tentative plans to renew their effort when the two houses reconvene. Conferences were held with Majority Leader Mondell and others prominent on the Republican side of the House with a view to learning the prospects of having the McKenzie and Wright bills set on the calendar for early consideration. The McKenzie bill provides for acceptance of the Ford bid with the Gorgas steam plant excluded from the property, and the Wright bill would accept the Ford offer with Gorgas included.

Leader Mondell is quoted as having assured the Ford advocates that he saw no objection to having the Ford offer brought on the floor of the House early in the next session, although he pointed out that there is much other important legislation which has been pending for a longer period.

In the last week of the recent session of Congress, the Ford advocates abandoned their tactics of obstructing other legislation in an effort to have the Muscle Shoals bills called up, because it was realized that nothing could be accomplished in the short time remaining. Leaders of the movement declared for an aggressive fight when Congress meets unless the measures are given early consideration.

Hearings also will be asked immediately by Representative Hull on his resolution to refer the whole question of disposition of the Muscle Shoals properties to the Secretary of War with power to act.

Sheffield Steam Plant Loaded

Electrical energy being generated at the government steam plant at Sheffield, Ala.—one of the Muscle Shoals plants—is now being sent to the rescue of industry in various communities of southeastern United States, being relayed by intervening systems to aid industry as far as 600 miles away, according to a statement made public in Washington by Thomas W. Martin, president of the Alabama Power Co.

Several thousand miles of high voltage transmission lines are being used, Mr. Martin states, and with the various interconnections in Alabama, Tennessee, Georgia, North Carolina and South Carolina, the system now in use is shown to be the largest in operation in the whole country.

Demand for Power

"There is an unusual industrial demand for power in this section," Mr. Martin says. "This, coupled with the coal shortage, the inability to obtain prompt deliveries of coal and the drought, has brought about a serious situation. The water-power plants and reserve steam plants in some parts of North and South Carolina and Georgia have been unable to take care of the power requirements of cotton mills and other industries in various communities in those states. Therefore, the Sheffield steam plant is now being operated by the power companies for the benefit of the public in the entire Southeast through interconnection of the lines of the companies in the states of Alabama, Tennessee, Georgia and North and South Carolina. The Sheffield plant is nearer the coal mines than other plants and the wheels of industry are being turned again, by that plant, in many far away communities."

The proximity of the steam plants in Alabama to the coal fields of that state makes it feasible to operate them when other plants remote from those fields have difficulty in obtaining fuel. Owing to the fact that this superpower zone is in actual operation at this critical period, several of the largest cotton mills in that section are able to continue at work.

German Sale of Alsace Petroleum Fields Set Aside

The petroleum fields of Pechelbronn (Alsace) were owned, previous to 1914, by two German societies, the Allgemeine Birgemeinegesellschaft and the Deutsch Erdol Aktiengesellschaft. After the armistice the fields were sold by the German societies to a Swiss society, Laterra, which was subsequently consolidated with another Swiss concern, L'Union Internationale des Petroles. The French Government placed the fields under sequestration, their administration being given to the Société Alsacienne d'Etudes Minieres. The Swiss societies recently requested the civil court to validate certain attachments of the property of the Société Alsacienne d'Etudes Minieres and, on the other hand, the Office des Biens et Interets Privés requested the lifting of the attachments. The court, according to information recently received by the Department of Commerce, has rejected the demand of the Swiss societies, stating that under the terms of the treaty of peace all enemy property was to be under the administration of France, and that the Pechelbronn fields had been unduly sold by the German owners.

Germany Rapidly Restoring Nitrogen Fixation Plants

At the meeting of the British Association held at Hull on Sept. 12, J. A. Harker, in the course of a paper on "Post-War Progress in the Fixation of Nitrogen," said Germany was finding vast sums for the restoration and development of her plant for the fixation of nitrogen. The figures Dr. Harker gave show that in 1913 Germany used 200,000 tons of fixed nitrogen, and by May of this year she was already producing and using at the rate of 290,000 tons per annum. She had by no means reached the limit of her capacity, and by the end of the year he estimates that the output will be at least 500,000 tons.

Time Extension for Chemical Foundation

Month More Allowed for Filing Answer —Situation Complicated by Trademark Clause

The Department of Justice has instructed the District Attorney in Delaware to consent to a 30-day extension of time in which the Chemical Foundation may file its answer to the bill in equity demanding the return of the 4,700 former German patents. The consent was granted on the condition that both parties, the Department of Justice and the Chemical Foundation, cooperate to obtain a speedy settlement of the controversy, which is reaching serious proportions due to the trademark clause in the new tariff bill.

Sept. 28 was the date originally set for the filing of the Foundation's answer. The extension plea was made on the ground that the bill was of such length that more time was necessary properly to prepare its answer. Attorney-General Daugherty, in a statement last week, said that the department realized that more time was essential and that it had no disposition to force the Foundation into trial until it had been given time in which to prepare its defense. If the Delaware court grants the extension, and confidence is expressed that it will, the Chemical Foundation must file its answering plea on Oct. 27.

Trademark Clause Tangles Situation

The government is anxious that the question of title to the patents be settled as speedily as possible. A clause inserted in the Fordney-McCumber tariff bill makes it illegal to import into the United States "any merchandise if any such merchandise or the label, sign, print, package, wrapper or receptacle bears a trademark owned by a citizen of, or by a corporation or association created or organized in the United States."

Many of the trademarks included in the purchase by the Chemical Foundation are internationally known, and the trademark or trade name could not be changed without losing practically all the old trade. It is generally predicted that the German manufacturers, rather than injure their own markets by changing the trademarks on these products, mostly pharmaceuticals and dyes —will abandon the American market if the Chemical Foundation is victor in the suit.

Officials freely admit that it is a complicated situation and are unwilling to predict the final solution, even if the government is able to set aside the sale.

No More American Caustic for Germany

The demand for American caustic soda in Germany has ceased suddenly according to recent advices to government officials. No report has been received as yet explaining definitely why it became necessary for German interests to purchase such large amounts of caustic soda in this country.

English Develop New Fertilizer From Straw

Valuable Farmyard Manure Produced by Action of Bacteria on Cellulose

A process of leading importance in agriculture has been developed by H. B. Hutchinson and E. H. Richards at the Rothamsted Experiment Station at Harpenden in Hertfordshire, England. It consists in producing farmyard manure from straw in the form of humus with its full complement of nitrogen, or about 2 per cent, within 3 months and under easily controlled conditions. The process is patented and experiments are under way in several stations in England to work out the simplest and most available technique. The manure is a well-disintegrated, plastic material in which the tubular character of the straw has been to a great extent destroyed.

Home Made Fertilizer

The maximum results are obtained by subjecting the straw to the action of a culture of aërobic cellulose-destroying organisms with the requisite moisture and the addition of nitrogen as ammonia, diluted urine, urea, ammonium carbonate, ammonium sulphate or cyanamide, to start the reaction. Unless the water is very hard, lime in some form is needed also—that is, soluble nitrogen is supplied at the rate of 0.72 part nitrogen to 100 parts of dry straw. Then little or no loss of nitrogen ensues and the final product contains, as stated above, about 2 per cent. This is also about the same proportion that is contained in the feces of cattle.

An alternative method in which inclosed containers are used and the air supply regulated provides gas (methane) for lighting and driving machinery on the estate of Lord Liveden, but it seems questionable whether the cost of installation to produce this convenience would not be too great for ordinary farm practice.

Superior Properties

The extraordinary value of farmyard manure as compared with nitrogen in any other form and the invigorating effect of the added humus to the soil make the discovery of leading importance. Straw of itself is not a useful fertilizer; indeed in many cases it depresses the crop. But once it is decomposed in this manner its value is immediately developed and many pot and field cultures show it to be a true farmyard manure. The straw and the organisms working on it must have abundance of air and just enough but not too much nitrogen. Ordinary urine is too concentrated and destroys the bacteria. Straw immersed in water or in urine will not undergo change. Therefore control of these factors is necessary, although it is believed that processes will shortly be worked out to make any intelligent farmer able to transfer all of his straw into about half its weight of this precious nitrogen-bearing humus. What the invention may mean to the farmers of the West, for instance, in improving their wheat crop with the aid of a proper manure spreader needs no comment. The same may be said of the wheat farmers of Canada and of the ranchers who burn their flax straw in the Dakotas.

Heat Standard for Gas Is Established in New York

For 15 years there has been a distinct tendency toward adoption of heating value standards for gas quality to replace candle-power requirements. New York City has been the outstanding example where candle-power standards remained until very recently. By order entered on Aug. 30, the New York State Public Service Commission adopted for all gas companies in greater New York a heating value requirement of 537 B.t.u. per cubic foot monthly average, specifying that no daily average should be less than 525 B.t.u. Thus practically the last candle-power requirement of consequence in the country is superseded.

There are two other rather interesting requirements as to gas quality in the commission order. The first specifies that the gas must not contain more than 15 per cent inert constituents. It is doubtless the expectation that this rule will prevent the practice, which has seemed to be particularly prevalent abroad, of making unnecessarily low-heating value gases through excessive vacuum on retorts or slovenly operation with water-gas equipment. The requirement is one of the first where such limit on the total of oxygen, nitrogen and carbon dioxide in a gas has been fixed.

The second novel requirement in this order provides that the heating value shall not have a variation greater than 5 per cent during any 3 consecutive days. This specification is intended to prevent the practice, which has occasionally been found in smaller plants, of running very close to the average requirement until near the end of the month and then bringing up the average by excessively high heating values during the last few days. The result of such practice is, of course, very bad service, because uniformity of quality is of first importance.

The new requirements took effect on Oct. 1.

American Interests Get Oil Concessions in Czechoslovakia

Czechoslovakian official sources announce the formation of a petroleum company having a capital of 100,000,000 crowns. Half of the capital will belong to the government, in exchange for which the Franco-American Standard Oil Co. is granted a monopoly for the exploitation of the oil lands which have not yet been bored. A small part of the capital, about 4,000,000 crowns, will be underwritten by the Credit Bank of Prague, while the remainder will be held by the Franco-American Standard Oil Co.

Power Exposition of Interest to Industries

Show in New York Will Cover All Phases of Development and Utilization of Power

Engineers well known in industrial circles make up the advisory committee which is guiding the National Exposition of Power and Mechanical Engineering. This exposition will open at the Grand Central Palace, New York City, on Dec. 7 at noon and will extend through to Dec. 13, except the intervening Sunday. It will immediately follow the annual meetings of the American Society of Mechanical Engineers and the American Society of Refrigerating Engineers. Irving E. Moultrop, of the Edison Electric Illuminating Co., of Boston, heads the advisory committee, and his colleagues are: Dexter S. Kimball, president of the American Society of Mechanical Engineers; Alexander G. Christie, chairman of the power division A.S.M.E.; Fred Felderman, president of the National Association of Stationary Engineers; Milan R. Bump, president National Electric Light Association; N. A. Carle, vice-president, Public Service Production Company of New Jersey; E. B. Katte, chief engineer, electric traction, N.Y.C.R.R. Co.; Fred R. Low, editor *Power;* David Moffat Myers, consulting engineer; Calvin W. Rice, secretary American Society of Mechanical Engineers.

Stress Engineering Features

This advisory committee is keenly alive to the importance of an exposition that will stress the engineering phases of the problems involved in the economical uses of fuel and the more effectual generation and utilization of power. The effect of such an exposition must be far reaching and the plan outlined by the committee insures a show that will benefit the manufacturer who uses only a small boiler for process steam as well as the engineers of the cement, ceramics, metallurgical and power generation industries, whose fuel and power problems are extensive and severe.

The list of firms which have already reserved space shows that all apparatus and materials used in harnessing the energy released from fuels will be represented. The general appreciation of the importance of the exposition further insures the showing of the newest devices and best methods.

Program of Meetings

The program for the week has been arranged so that those interested especially in fuels and power can attend the technical sessions on these subjects at the annual meeting of the American Society of Mechanical Engineers. Sessions on ash-handling machinery, stokers and steam utilization have already been announced; others are to come later and it is probable that the papers on these subjects will be amplified by the exhibits at the exposition.

Tax Returns Show Volume of Chemical Business

Over 3,000 Companies in Chemical and Allied Fields Paid Nearly $100,000,000 in 1920

The net income of the 3,047 corporations engaged in the manufacture of chemicals and allied substances for the calendar year 1920 was $441,369,660. This total is taken from a compilation just made by the Bureau of Internal Revenue. The total number of manufacturing chemical concerns which made returns to the Bureau of Internal Revenue was 5,826. Of that number 2,779 reported no net income. The total deficit reported by those concerns was $96,439,756.

The 3,047 concerns reporting net income paid taxes to the extent of $98,163,376.

The concerns engaged in manufacturing chemicals proper which made returns in 1920 numbered 908. Of these, 516 reported net incomes aggregating $42,034,248. They paid taxes to the extent of $9,823,369. The remaining 392 concerns reported no net income, with deficits of $7,919,341.

Paints and Oils

The Revenue Bureau figures show that 648 concerns engaged in the manufacture of paints and varnishes made returns. Of that number 438 reported net incomes aggregating $17,371,134. The tax paid by these concerns totaled $3,688,282. The remaining 210 concerns reported no net income, with deficits totaling $3,154,247.

There were 457 concerns engaged in the preparation of vegetable and animal oils. Of that number 156 reported net incomes aggregating $1,272,359. They paid taxes to the amount of $3,820,496. The remaining 301 concerns reported no net income, with deficits totaling $12,455,527.

Petroleum and Refining

Petroleum and mineral oil refining is included under the chemical activities. Those concerns numbered 390. Of that number 203 reported net incomes aggregating $245,599,730. The tax collected from those companies totaled $54,554,347. The remaining 187 concerns reported no net income, with deficits totaling $4,570,838.

Soap

Soap-manufacturing concerns making returns numbered 157. Of that number 63 reported net incomes totaling $3,657,175. They paid taxes amounting to $632,501. The remaining 94 concerns reported no net income, with deficits totaling $14,798,185.

Fertilizers

Two hundred and thirty concerns engaged in the manufacturer of fertilizers made returns in 1920. Of that number 107 reported net incomes totaling $5,480,826. Their total tax bill was $885,771. The remaining 123 concerns reported no net income, with deficits totaling $25,788,478.

The bureau classifies returns from 3,036 as manufacturers of "all other chemicals and allied substances." Of that number 1,564 reported net incomes totaling $111.768,470. They paid taxes to the extent of $24,758,610. The remaining 1,472 concerns reported no net income, with $27,753,740 deficits.

Bureau of Mines Completes Fluorspar Investigation

Accurate information on methods of mining, milling and utilization and on costs of production of fluorspar is so lacking that it has been considered advisable by the Bureau of Mines to investigate all phases of the fluorspar industry in the United States. At the request of and in company with several Eastern fluorspar producers, examination has been made of the principal fluorspar deposits of the Western states. This examination was followed by an intensive study of the producing mines in Illinois and Kentucky. It was found that most of the deposits in the Far Western states were small and could not be relied on to produce much surplus over the needs of the Western states. Costs of production in the Illinois-Kentucky field have increased greatly, owing to the increasing depth of the principal mines, the large amount of water that must be pumped and the increased costs of labor and supplies. A report on all phases of the fluorspar industry is in preparation.

Pacific Coast Steel Plants Consolidate, Planning Expansion

The Pacific Steel Corporation, San Francisco, Calif., recently organized to take over and consolidate the Pacific Coast Steel Co., the Southern California Iron & Steel Co. and the Milner Corp., is perfecting plans for immediate enlargement in the different plants of the affiliated interests, estimated to cost in excess of $7,000,000. The Pacific Coast company has plants at San Francisco, Portland and Seattle. All of these will be extended with new buildings and equipment, including practically a doubling of the present capacity at the San Francisco works. The Southern California company has going plants at Los Angeles and San Diego, both of which will be enlarged in the near future.

Prospective plans provide for the early erection of a new blast furnace on site to be selected in Utah, estimated to cost approximately $5,000,000. It will be devoted to the production of pig iron, which will be utilized at the different steel mills of the company. The new corporation proposes to arrange facilities for the complete manufacture of fabricated steel shapes and other steel products from raw materials on the Pacific coast. It is capitalized at $20,000,000, with 200,000 shares of common stock, no par value. Organization plans and the election of officers and directors are now being consummated. The company is represented by T. T. C. Gregory, attorney, Insurance Exchange Building, San Francisco.

Agricultural Chemists to Meet in Washington

Variety of Food and Drug Products to Be Discussed at Annual Convention

The thirty-eighth annual convention of the Association of Official Agricultural Chemists will be held in Washington, D. C., at the Raleigh Hotel, beginning Nov. 15.

The morning session, the first day of the meeting, will include discussions on the general subjects of water, tanning, insecticides, soils and food products. That afternoon symposiums will be held on fertilizers, dairy products, baking powder, fats and oils and inorganic plant constituents. The drug section will meet at the same time and twenty-one papers on the preparation, analysis and properties of various drugs are scheduled.

The Thursday sessions will be devoted to papers on foods, food preservatives and the testing of food products. Vinegars, flavoring extracts, gelatine, tea, coffee, spices, cereal foods and beverages will come in for a share of the discussion.

Harvey W. Wiley, honorary president of the association, will address the meeting Thursday morning at 11 o'clock. F. P. Veitch, president of the association, will also speak at this time and will introduce Senator E. F. Ladd, who is tentatively scheduled for a talk. Secretary of Agriculture Wallace is on the Thursday afternoon program.

Friday will be devoted to committee reports, fourteen reports being expected.

Electric Welding by Alternating Current

A system of electric arc welding using an alternating current, the invention of A. Tornblom, a Swedish engineer, has been placed on the market by Carlson-Hedborg-deVerdier, Stockholm, under the trade name "Wex system." Use of the alternating current in electric welding is an important feature in view of the fact that most shops use this current. The rheostat is designed to keep the current continuously at even strength. An economic advantage is that welding may be made with a comparatively weak current. Thus it requires only 3.6 kw.-hr. to melt 1 kg. of iron.

Fertilizers Given Transportation Priority by I.C.C.

By including fertilizers among the commodities given priority in transportation in its service order 25, the Interstate Commerce Commission has given official recognition for the first time to the essential character of the fertilizer industry. The effect of service order 25 has been to relieve very greatly the situation which for a time made it impossible to move fertilizers in anything like the volume necessary to meet the country's requirements. The situation was aggravated by the seasonal character of this movement.

Safety Institute of America Plans Accident Prevention Week

More than 6,000 industrial plants in New York City employing nearly one million men and women will participate in the campaign for the prevention of accidents which will be launched during the week of Oct. 8 to 14 by the Safety Institute of America through the Public Safety Committee, of which Elbert H. Gary is chairman. This announcement was made by Laurence Vail Coleman, director of the Safety Institute of America, following the appointment of Henry D. Sayer, Commissioner of the New York State Department of Labor, as chairman of the industrial committee for the safety week campaign.

In urging the industries to conduct a safety campaign within their own plants, the Institute believes that it is reaching effectively not only workmen but fathers and citizens, thus making a direct contribution to the campaign.

Commissioner Sayer is asking each of the 3,000 plants under the jurisdiction of his department to conduct a safety drive within its own gates throughout safety week, to hold mass meetings of employees which will be addressed by safety speakers and at which in many cases safety motion pictures will be shown. Each plant has been requested to post at each entrance and on bulletin boards throughout the plant the "Don't Get Hurt" posters issued by the Safety Institute.

Big Australian Power Project Progressing Rapidly

Electrification of the State of Victoria, Australia, by the utilization of the Morwell brown coal is being rapidly carried forward by the State Electricity Commission, according to reports to the Department of Commerce.

The main power house, which is to be situated at the new township of Yallourn, about 5 miles from Morwell, and which is expected to be in operation in about 2 years' time, will have an initial capacity of 50,000 kw. and will contain five 12,500 turbo-generators. All the principal contracts for the plant and machinery for the main power station at Yallourn are being placed, and the reports indicate that the progress with the manufacture of the machinery is good. A considerable portion of the equipment has already been delivered, while the manufacture of the five turbo-alternators and of the condensing plant is well advanced.

The greater part of the preparatory work of the site has been completed; contractors for the steel work for the power station are at work on the ground and steel is arriving. Gangs have been organized for the erection of the transmission line (over a distance of 112 miles) for which much of the material is now at hand.

The erection of the auxiliary station at Newport is proceeding satisfactorily and justifies the expectation that the station will be in operation by May, 1923, as originally intended.

Pottery Firms Indicted

(Continued from page 709)

Arthur Plantier, Sr., president and general manager of the Sanitary Earthenware Specialty Co., Trenton, N. J.

George C. Kalbfleisch, factory manager of the Standard Sanitary Manufacturing Co., Kokomo, Ind.

Sigmund B. Kling, factory manager of the Standard Sanitary Manufacturing Co., Tiffin, Ohio.

Willard C. Chamberlain, sales manager of the Standard Sanitary Manufacturing Co.

Elzey S. Aitkin, general manager of the Trenton Potteries Co., Trenton, N. J.

J. E. Wright, president and general manager of the Wheeling Sanitary Manufacturing Co.

Chris Horton, president and treasurer of the Horton Pottery Co., Chillicothe, Ohio.

Surplus Picric Acid in Demand for State Roads

Over 4,000,000 lb. of the War Department's surplus picric acid has been distributed to date through the Bureau of Public Roads. All orders received from states have been filled as follows: California, 72,400 lb.; Connecticut, 20,400; Georgia, 37,800; Idaho, 135,100; Indiana, 24,000; Iowa, 57,300; Kansas, 16,100; Louisiana, 37,300; Michigan, 804,800; Minnesota, 1,133,300; Mississippi, 23,000; Missouri, 65,000; Montana, 35,200; New York, 100; North Carolina, 117,200; Ohio, 42,000; South Carolina, 17,100; Tennessee, 81,100; Washington, 72,600; Wisconsin, 1,456,800, and Vermont, 3,200.

Personal

Dr. JAMES C. ANDREWS has severed his connection with E. I. du Pont de Nemours & Co. in order to teach physiological chemistry in the medical school of the University of Pennsylvania, Philadelphia, Pa.

GEORGE A. BOLE has been appointed superintendent of the ceramic experiment station of the Bureau of Mines at Columbus, Ohio. For the past 5 months Mr. Bole has been acting superintendent of the station. Mr. Bole joined the Bureau of Mines staff on Aug. 6, 1921, as an associate chemist. For 9 years prior to that time he had been professor of ceramic chemistry at Alfred University. He was graduated from Geneva College in 1906 and from Columbia University in 1911.

RICHARD H. EURICH, formerly with the Westinghouse Electric & Manufacturing Co., Trafford, Pa., is now vice-president and works manager of the Morristown Electric Steel Foundry, Morristown, N. J.

LEON W. PARSONS has tendered his official resignation as assistant director of the Research Laboratory of Applied Chemistry and assistant professor of applied chemical research of the Massachusetts Institute of Technology, to take effect Nov. 1, in order to accept the position of chief chemist with the Tide Water Oil Co. His headquarters will be at Bayonne, N. J.

Dr. ROBERT E. SWAIN, head of the department of chemistry at Stanford University, spoke before the Southern California Section of the American Chemical Society, Sept. 28, on "Some Aspects of the Smoke Problem."

ROBERT C. WEED, formerly metallurgist for Fairbanks, Morse & Co., is now with the Minnesota Steel Co., Duluth, Minn.

W. B. WIEGLAND has recently been appointed general manager of the reorganized Ames-Holden McCready, Ltd., a wholesale rubber goods concern of Montreal. Mr. Wiegland has been an executive of the company during the past 3 years.

The following have joined the staff of the research laboratory of the Eastman Kodak Co., Rochester, N. Y.: Dr. Helge Schibsted, formerly with the Atmospheric Nitrogen Co.; Clyde Brockett, Massachusetts Institute of Technology, 1922; Alasco Burgess, Bates College, 1922; D. Henry Harris, Massachusetts Institute of Technology, 1922; Roger P. Loveland, Grinnell College, 1919.

The Massachusetts Institute of Technology, Cambridge, Mass., in preparation for the opening of its new academic year on Oct. 2, announces a number of additions to its faculty and instructing staff. Chief among these are the appointments of W. Spencer Hutchinson to the professorship of mining, Dr. G. B. Waterhouse to the professorship of metallurgy and Dr. Frederick G. Keyes to be acting head of the department of chemistry. Professor Hutchinson was graduated from the Institute in 1892 after having studied in the civil engineering and mining departments. Professor Waterhouse was born in England 40 years ago and was educated at Sheffield, where he received the degree of Bachelor of Metallurgy. He came to the United States in 1900 and later studied at Columbia University, where he obtained the degree of Doctor of Philosophy in 1906. Professor Keyes, the present acting head of the department of chemistry, is a graduate of Rhode Island State College and of Brown University. At the latter institution he received the degree of Doctor of Philosophy in 1909. In 1920 he first joined the staff of the Institute. From 1913 to 1916 he was chief engineer of the Cooper-Hewitt Co., and in 1916 he returned to the Institute as associate professor of physicochemical research.

Obituary

FRANK M. HAWKINS, who had been actively connected with the Crouse-Hinds Co. for more than 25 years, died recently.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Clearing the Way for Business Progress

Settlement of Labor, Tariff and Bonus Issues Removes Obstacles That Have Retarded Improvement—Unemployment Now Non-Existent—Rising Wages and Prices

NOT AT ANY TIME in recent months have fundamental business conditions appeared in a more favorable light. The wreckage of industrial strife has been almost entirely cleared away, the uncertainties of the tariff are definitely ended, the threat of the bonus has been effectively defeated and, finally, the summer lull in production and demand is gradually giving way to the seasonal activity that usually accompanies the fall and winter months. Thus one by one the serious obstacles in the path of the present business revival have been removed, leaving the way clear for the operation of those factors making for progress and improvement.

Tariff and Bonus Legislation

From a national viewpoint the President's veto of the bonus bill and the enactment of the new tariff are of most significance to business. The former action though not entirely unexpected, has had a cheering influence on those who have been appalled by the prospects of a four-billion-dollar drain on the public treasury. The effects of the new tariff are problematical. It will probably yield an annual revenue in the neighborhood of $400,000,000, but its opponents contend that it will cost more than that in more expensive living conditions and unfavorable reaction on our export trade.

That the industrial situation has improved with the settlement of the strikes goes without saying. Over 600,000 coal miners and 400,000 railway shopmen are back at their jobs and the textile workers' strike in New England has finally ended after 8 months of struggle. There are, however, certain cumulative effects that must still be accounted for by industry. The tremendous economic losses arising from interruption and disturbance in these basic industries must be paid for in the long run, even though their full effect may not be felt immediately.

Coal and Transportation

Two closely related factors which may yet have a retarding effect on further business expansion are fuel and transportation. Both at present, however, are most encouraging. Normal production at the anthracite mines during the week ended Sept. 23 brought the total output of coal, anthracite and bituminous, up to 11,650,000 net tons. Soft coal production of 9,661,000 tons compares with 8,187,000 tons in the corresponding week of 1921 and 10,685,000 tons in 1920. Car loadings, both of coal and other revenue freight, are setting new high records. More cars were loaded during the week which ended Sept. 16 than during any week since Oct. 29, 1921. Coal loadings alone amounted to 172,241 cars, the largest number during any single week since the beginning of the miners' strike. This was an increase of 32,671 cars over the preceding week and 6,730 over the same week of last year.

Unemployment is no longer a factor in the industrial situation. In comparison with 5,500,000 workers out of employment at this time last year, the *Guaranty Survey* estimates that at present only 1,500,000 are seeking work. The Bureau of Labor Statistics has recently reported the volume of employment in 2,595 representative establishments covering 1,249,144 employees in forty-two manufacturing industries. Of this number thirty industries reported increases in the number of persons employed in August as compared with July. The largest increase, 30.6 per cent, was in stamping metal products. Fertilizers showed an increase of 16 per cent and chemicals an increase of 3.2 per cent. The results reported for a few of the more important industries are shown in Table I.

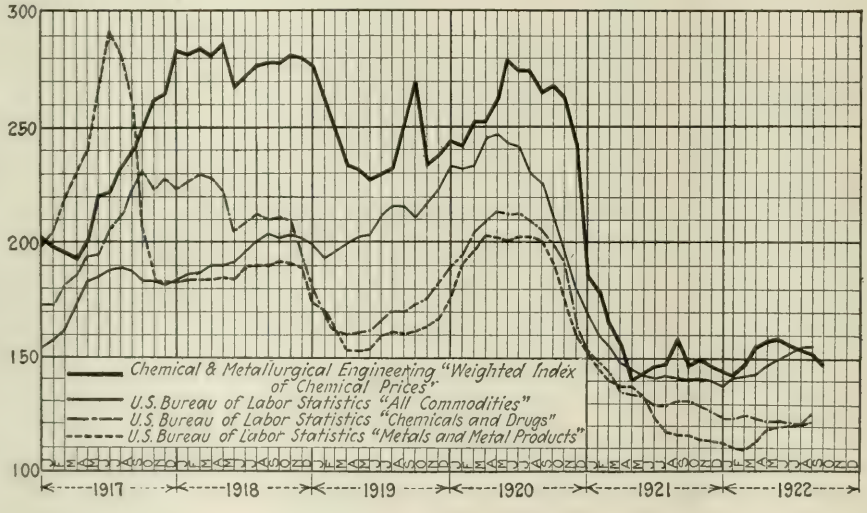

FIG. 1—THE TREND OF CHEMICAL AND METAL PRICES, 1917-1922

Wage Increases and Inflation

The advance of 20 per cent in wages made effective by the U. S. Steel Corporation appears to have been the cue for all other industries to follow suit. It is a very serious question, however, as to whether or not the rising tendency of both prices and wages is to be regarded as a favorable development. There is abundant evidence to indicate that widespread inflation always has its beginnings in just such general move-

October, 1921	151
October, 1920	263
April, 1918 (high)	286
April, 1921 (low)	140

Seven of the twenty-five commodities included in this index advanced in price during the past week. There were no declines. Higher prices were reported for acetic and citric acids, barium chloride, formaldehyde, glycerine, methanol and crude potassium carbonate.

BLE I—COMPARISON OF EMPLOYMENT IN JULY AND AUGUST, 1922

Industry	Establishments	Period of Payroll	Number on Payroll in July, 1922	Number on Payroll in Aug., 1922	Per Cent Increase or Decrease
tomobiles..	97	1 wk.	152,147	152,827	+ .4
tomobile ires.....	34	1 wk.	30,343	30,786	+ 1.5

* Increase less than one tenth of one per cent.

ents as this. Already we hear talk of econdary inflation," so called, per-aps, for the purpose of mitigating its ost undesirable effects. A recur-nce of conditions existing in 1919 d 1920 can be viewed only with ap-rehension by those interested in fun-amental business conditions.

Thirty-three of the forty-two indus-ies included in the survey of the De-artment of Labor show increases in he total amount of payroll for August, 922, as compared with July. The per apita increase in earnings reported by me of these industries are as fol-ws: Iron and steel, 15.1 per cent; utomobiles, 8.6 per cent; fertilizers, 3 per cent; tires, 5.2 per cent; pot-ry, 5.1 per cent; glass, 4.8 per cent; emicals, 3.6 per cent; pulp and aper, 3.6 per cent, and leather, 2.2 er cent. Among the industries show-g a decrease in individual earnings as petroleum, with 3.6 per cent.

The Trend of the Chemical Market

A Review of the Principal Price Changes and Tendencies During the Third Quarter of 1922

The factors which have had most effect on the chemical market during the past 3 months are no longer of real significance. The uncertainties connected with the framing of the new tariff came to an end with its enactment on Sept. 21, 1922. The difficulties caused by the railroad shopmen's and the coal miners' strikes were largely relieved by their resumption of work. Except for the spasmodic activities resulting from threats of fuel shortage or transportation tie-up, the chemical market has been without any significant development.

Those who are in closest touch with the chemical market, however, are of the opinion that the fourth quarter of 1922 will witness a marked revival and a healthier condition of trading.

Market Features

The outstanding feature of the market has been the sharp advances on all commodities of an imported nature. *Barium carbonate*, quoted at $60 per ton during July, was advanced to $80 per ton since the passage of the tariff. *Barium chloride* showed a complete recovery from its temporary slump during August, and prices are again at the high level of $105 per ton, with all indications toward higher figures. The prussiates were another feature of marked interest. *Yellow prussiate of potash* was quoted during July at 31½c. per lb. and has steadily advanced to 37c. per lb. for the beginning of the last quarter. *Yellow prussiate of soda* has also shown signs of much livelier trading, and quotations were advanced from 21c. per lb. during July to 24c. per lb. for October. The price for this commodity in January, 1922, was 17¼c. per lb. *Caustic soda* for export has been a complete disappointment to producers. Their only consolation was the very active domestic demand from leading consumers. Contract prices remained at the same levels, with export figures somewhat lower at $3.55 per 100 lb. *Oxalic acid* increased in price from 14½c. per lb. in July to 17c. per lb. at the close of the quarter. *Calcium acetate* manufacturers increased quotations from $2.35 per 100 lb. to $2.75. Increased cost of production has been directly responsible for the several advances in this item. *Caustic potash*, 88-92 per cent, has shown considerable activity since the passage of the tariff and prices were advanced from 5½c. per lb. to 6½c. Late trading was of much larger volume than at any other time this year. *Bleaching powder* has also been one of the features of the market. Stressed lots have entirely disappeared during the interval and factors have experienced difficulty in filling old contracts. Quotations were advanced from $1.60 per 100 lb. in July to $2 per 100 lb. for October. *Formaldehyde* prices jumped from 8c. per lb. during July to 10½c. per lb. for October. Increased prices for *methanol* were directly responsible for the advance. Trading in this item has also shown additional activity. *Ammonium sulphate* prices were materially advanced from $3.50 per 100 lb. to $3.75.

A monthly comparison of the average prices of forty-five important chemicals in the New York market is to be found in the accompanying table.

COMPARISON OF THE AVERAGE MONTHLY PRICES IN THE NEW YORK MARKET FOR 45 IMPORTANT CHEMICALS

Article	Unit	Average Price for Month of Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Price on Oct. 1
cetic acid, glacial	Lb.	$0.10	$0.09	$0.09	$0.09	$0.09	$0.08½	$0.09½	$0.12	$0.11½	$0.11

The New York Market

NEW YORK, Oct. 1, 1922.

The new tariff has already shown its effect among imported chemicals and in many instances important advances were recorded. Consumers have changed their conservative methods of trading and it looks as though buyers are gaining confidence in the offerings of leading sellers. Throughout business circles a pronounced spirit of optimism is noted for the last quarter of the year. The tariff has caused a marked increase in citric acid, barium carbonate and chloride, tartaric acid, cream of tartar, prussiate of soda, fluoride of soda, barium nitrate, carbonate of potash, permanganate of potash and various other items. Formaldehyde was advanced 1c. per lb. due to the recent increase in methanol. The recent advance in acetate of lime has been reflected on all grades of acetic acid and acetone. The domestic demand for caustic soda and soda ash has continued very strong at recent levels. Export inquiry is somewhat dormant. Producers of alcohol have increased their prices of the denatured alcohol and methanol. The demand has shown noticeable improvement of late. Glycerine has also shown new advances to 18c. per gal. for the chemically pure in drums. No declines of any importance were recorded during the interval.

GENERAL AND SPECIAL CHEMICALS

Acetic Acid—Prices on all grades have been advanced by producers, due to the higher market on calcium acetate. Commercial 28 per cent is quoted at $2.80@$3.50 per 100 lb. The 56 per cent is held at $5.60@$6.30 per 100 lb. The demand is moderately active.

Acetone—Leading factors have advanced the market on quantity lots to 16½c. per lb. and smaller proportions at 17½c. per pound.

Barium Carbonate—Importers have advanced spot quotations to $80 per ton. Goods afloat were quoted in several quarters at $72 per ton in bond. The inquiry is fairly active, although actual transactions were very scarce.

Barium Chloride—Spot prices have been advanced to $105 per ton. The general tone of this market is very firm with holders not inclined to force any business. Buyers appear eager to purchase at the new levels.

Barium Nitrate—Importers are quoting much higher prices and name 9c. per lb. as the lowest figure on spot. Trading is rather quiet.

Bichromate of Soda—The condition of this market is quite steady, with prominent sellers asking 7½@7⅝c. per lb. The consuming inquiry is mostly for small lots.

Carbonate of Potash—Importers are asking much higher prices for this commodity. Spot quotations ranged around 6c. per lb. for the calcined 80-85 per cent. Demand is generally active.

Caustic Soda—Export prices remain quotably unchanged at $3.55 per 100 lb. for standard brand goods. The domestic demand, however, continues exceedingly active and quite a volume of business is being transacted. Spot goods is quoted at $3.75@$4 per 100 lb. Contract prices remain unchanged.

Chlorate of Potash—Imported material is quoted around 7½@7⅝c. per lb. Domestic factors quote 8½c. per lb. f.o.b. works. Demand is moderate.

Cream of Tartar—Leading importers are asking around 26½c. per lb. for spot goods. Buyers were not inclined to purchase at this high level and actual sales were very few.

Formaldehyde—Producers of this material were forced to advance prices due to the sharp advance of methanol. Factors quote 10½c. per lb. for available material in barrels.

Oxalic Acid—Manufacturers quote the market at 16¾c. per lb. f.o.b. works. Odd lots of spot goods have been offered as low as 16¾c. per lb. The general tone has been fairly active, but most sales were for small-lot requirements.

Permanganate of Potash—Spot quotations were advanced considerably and the lowest figure heard was 18c. per lb. U.S.P. crystals.

Prussiate of Soda—Spot goods are being held at higher prices, with sellers naming 24@25c. per lb. Few holders were willing to sell any round lots at the inside figure, as the general feeling among sellers is very bullish. Goods afloat were quoted around 24@24½c. per lb., duty paid. Demand is quite active.

VEGETABLE OILS

Linseed Oil—The market during the past week was rather easy and without any outstanding features. Crushers seemed quite anxious for new business at 88c. per gal., carload lots, on spot. October oil sold down to 85c. per gal. London reported a much higher market for oil, due to the covering of several short sellers. There was no special interest noted among buyers for imported material and the market was merely nominal at 52c. per gal., in bond. Foreign oil on spot held around 85@87c. per gallon.

Coconut Oil—A much better tone was to be noted throughout the past few weeks for all grades. Ceylon grade oil for October shipment from the coast reached 6⅞c. per lb., sellers' tanks. Ceylon type for immediate shipment from New York was quoted at 7⅞c. per lb., sellers' tanks. Spot goods in barrels ranged around 8¼c. per lb. Cochin type oil in barrels held around 8¾@9c. per pound.

Peanut Oil—Crude domestic material was somewhat limited to small lots. Recent sales were recorded around 8c. per lb., tank cars, f.o.b. mills. There were no offerings of Oriental peanut oil, due to the new tariff rates. Refined oil on spot was in fair demand at 12@12½c. per lb., in barrels.

Rapeseed Oil—The spot market for refined oil was quite irregular at 78@80c. per gal. Refined oil for shipment was quoted at 74@76c. per gal. The inquiry during the interval was dull.

The Chicago Market

CHICAGO, ILL., Sept. 28, 1922.

The industrial chemical market was very irregular during the past week. Price advances were numerous and holders were very reluctant to dispose of their supplies on quite a few items. Most of the price advances were due to higher duties imposed by the new tariff. Business in general was good, although no large orders from consumers were reported. Speculators were active in securing supplies of several items that were well protected by the new tariff, but their activities had little or no effect on the general condition of the market.

GENERAL CHEMICALS

Caustic soda was apparently in a firm position and supplies were reported to be moving in a good volume to the consuming trade. Prices were firm with the 76 per cent solid quoted in ton lots at $3.75@$3.85 per 100 lb. and the ground or flake at $4.25. *Caustic potash* was sharply advanced to 7½c. per lb. for the 88-92 per cent material and moved in a good volume. *Soda ash* was unchanged in price at $2.25 per 100 lb. for the 58 per cent in cooperage and the demand was good. *Sal soda* moved very well at $1.90 per 100 lb. for moderate lots in barrels.

Potash alum was quoted slightly higher, with a fair demand reported. The iron-free lump was available at 5½@6c. per lb. and the powder at 6¼@7c. *Sal ammonic* was in a firm position and the prime white 98-100 per cent material was quoted at 7¾c. per lb. *Barium chloride* was sharply advanced and only small lots were offered at $125 per ton. *Bleach* was in good demand and was quoted higher at $2.60 per 100 lb. for spot material. *Copper sulphate* was easy, with supplies plentiful at 6@6½c. per lb. *Carbon bisulphide* continued firm with only moderate supplies offered at 7½c. per lb. *Carbon tetrachloride* was slightly firmer, but the general quotation remained 9c. per lb. for the large drums. *Formaldehyde* was advanced to 10½c. following the advance in methanol and supplies were reported to be light in some quarters. *Furfural* was quoted at 35c. per lb. in 1000-lb. lots. Another advance occurred on *glycerine*, the c.p. material being quoted at 18@18½c. per lb. *Lead acetate* was advanced due to the higher price of acetic acid to 12@13c. per lb. for the white crystals. *Magnesium metal* was quoted higher due to the greater replacement cost. The powdered material was held at $1.35 per lb. by the principal dealer.

Bichromates were quoted slightly higher, with the potash at 12@13c. per lb. and the soda at 9@9½c. *Potassium permanganate* was in good demand, with only very small supplies available on spot. The U.S.P. crystals was quoted at 19@20c. per lb. *Soda bicarbonate* moved in a fair way to the consuming trade and was unchanged at $2.25 per 100 lb. *Sodium cyanide* was in fair demand and imported material was quoted at 25c. per lb.

The Iron and Steel Market

PITTSBURGH, Sept. 29, 1922.

Apart from the heavy buying of rails, which is a seasonal movement, the finished steel market is distinctly quiet. In a particular sense the rail buying is the exception that tests the rule, the rail buying having been brought about by the rail mills, apparently, for the purpose of supplying needed reinforcement to order books. The mills announced that, effective at the beginning of October, the rail price would advance from $40 to $43 a gross ton, giving the railroads meanwhile an opportunity to buy at the old price, with the stipulation that delivery should be completed by July 1. The railroads have taken hold freely, to profit by the saving, and the total of rails ordered will lie between 1,000,000 and 1,300,000 tons.

CORPORATION AND INDEPENDENT PRICES

Various isolated incidents, viewed together, represent a merging of prices of the Steel Corporation and the independents. Until very lately the two parties were apart on nearly all commodities, the corporation being unable to enter orders for early delivery, while most of the independents could make rather early delivery and obtained what amounted to a delivery premium. In wire products the independents were $3 a ton above the corporation, while the corporation has now advanced $2 and the independents are reducing their prices by the extra dollar. In bars, as indicated above, purchases from some independents can now be made at 2c., while on the other hand the corporation has withdrawn its 1.90c. price on bars, leaving its price at 2c. In shapes there is also a common price of 2c. As to plates, it is doubtful whether at the present time any independent is willing to go as low as 2c., which seems to be the corporation price. Small lots of bars and shapes for very early shipment are bringing above 2c. In the case of pipe there has been no difference between the corporation and the independents except that one independent, able to make relatively early delivery, is asking prices $2 to $3 a ton above the regular figures.

In sheets no direct comparison can be made, because the corporation, with a price schedule based on 3.35c. for common black, is sold out until it opens its order books for the first quarter. Independents are getting 3.50c. on most of the tonnage, but mills able to make particularly early deliveries are obtaining up to a 3.75c. basis on small lots. In automobile sheets the disparity is great, much independent tonnage going at 5.25c., against 4.70c. represented in the last sales of the corporation.

Steel production is now at about two-thirds of capacity, having been at close to three-fourths of capacity in June and having dropped to one-half capacity at the end of August.

While the steel interests have sharply increased their blast-furnace operations in the past 30 days, the merchant furnaces have been unable to do likewise, there being the great difference in position that the steel interests have by-product coke ovens and coal mines, while the merchant furnaces depend chiefly upon purchased Connellsville coke, supplies of which continue very light. Only two or three merchant furnaces in this general territory have resumed.

The pig iron market has been stagnant for several weeks, consumers being apparently unable to pay prices asked, while at best very little tonnage could be obtained by paying one price or another. The Cambria Steel Co., Johnstown, now operating six blast furnaces, has been offering merchant pig iron at prices below the valley basis at points where there is no great freight disparity. It has sold 2,000 tons of basic to a West Virginia sheet interest at $30 Johnstown, and 1,000 tons of bessemer (silicon 2 to 2.50 per cent) to a Pittsburgh consumer at $33.50 Johnstown. It is now quoting $30.50 Johnstown on basic iron, $32 on malleable and $32.50 on foundry. Freight Johnstown to Pittsburgh is $1.77, the same as the valley rate to Pittsburgh.

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.95 — $1.00
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.15 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.53 — .55
Beta-naphthol, tech	lb.	.23 — .25
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.32 — .34
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.72 — .75
Dipnenylamine	lb.	.54 — .56
H-acid	lb.	.72 — .75
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.10 — .11
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.07½ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35
Nitro-toluene	lb.	$0.15 — $0.10
N-W acid	lb.	1.15 — 1.30
Ortho-amidophenol	lb.	2.10 — 2.15
Ortho-dichlor-benzene	lb.	.17 — .20
Ortho-nitro-phenol	lb.	.80 — .85
Ortho-nitro-toluene	lb.	.10 — .13
Ortho-toluidine	lb.	.12 — .14
Para-amidophenol, base	lb.	1.20 — 1.25
Para-amidophenol, HCl	lb.	1.25 — 1.30
Para-dichlorbenzene	lb.	.17 — .20
Paranitroaniline	lb.	.72 — .80
Para-nitrotoluene	lb.	.55 — .65
Para-phenylenediamine	lb.	1.55 — 1.60
Para-toluidine	lb.	.85 — .90
Phthalic anhydride	lb.	.35 — .38
Phenol, U. S. P., drums	lb.	.21 — .22
Pyridine	gal.	1.75 — 2.75
Resorcinol, technical	lb.	1.50 — 1.55
Resorcinol, pure	lb.	2.00 — 2.10
R-salt	lb.	.55 — .60
Salicylic acid, tech., in bbls.	lb.	.25 — .27
Salicylic acid, U. S. P.	lb.	.29 — .30
Solvent naphtha, water-white, in drums, 100 gal.	gal.	.27 — .32
Solvent naphtha, crude, heavy, in drums, 100 gal.	gal.	.12 — .14
Sulphanilic acid, crude	lb.	.24 — .26
Tolidine	lb.	1.20 — 1.30
Toluidine, mixed	lb.	.30 — .35
Toluene, in tank cars	gal.	.25 — .28
Toluene, in drums	gal.	.30 — .35
Xylidines, drums, 100 gal.	lb.	.40 — .45
Xylene, pure, in drums	gal.	.40 — .45
Xylene, pure, in tank cars	gal.	.45 — .....
Xylene, commercial, in drums, 100 gal.	gal.	.33 — .35
Xylene, commercial, in tank cars	gal.	.30 — .....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

AJO—The New Cornelia Mining Co. has awarded a contract to the Wisconsin Bridge Co. for the erection of the building for its proposed concentrating and flotation plant, and will arrange a list of equipment for installation at an early date, to include ore crushers, conveyors, electric equipment and other operating machinery in addition to primary concentrating machinery. The plant is estimated to cost in excess of $2,500,000.

California

LONG BEACH—The Pacific Petroleum Products Co., Los Angeles, is selecting a local site for the construction of a new refinery, to be used primarily for the production of gasoline. L. C. Monks heads the company.

LOS ANGELES—The Mathews Paint Co. has plans under way for the construction of a new 1-story plant, 50x170 ft., on the San Fernando Road, near Ave. 26, to cost about $17,000. The Moran Co., 206 Kerckhoff Bldg., is architect.

VISALIA—The Kaweah Lime Products Co. has plans under way for the construction of an addition to its plant at Terminus, near Visalia, to cost about $25,000. A. C. Root is general manager.

LOS ANGELES—The Downing Process Laboratories, Inc., 6363 Santa Monica Blvd., is having plans prepared for the construction of two 2-story additions, 40x60 ft. and 32x50 ft. respectively. Edward T. Flaherty, 435 I. W. Hellman Bldg., is engineer.

Connecticut

ROCKY HILL—The Connecticut Foundry, Inc., has awarded a contract to C. P. Waterman, Inc., 43 Framingham Ave., Hartford, for the construction of a 1-story foundry addition, about 20x42 ft.

Delaware

WILMINGTON—A 2-story foundry, 98x240 ft., will be constructed at once at the plant of the Hilles & Jones Division of the Consolidated Machine Tool Corp., 9th and Church Sts., estimated to cost about $40,000.

District of Columbia

LANGDON—The Fleischmann Co., 701 Washington St., New York, N. Y., has awarded a contract to the Schneider-Spleidt Co., Washington, D. C., for extensions and improvements in its local 3-story yeast-manufacturing plant, to cost about $50,000.

Illinois

EAST ALTON—The Western Cartridge Co. is completing plans for the construction of a 1-story addition to its brass mill, 86x240 ft., estimated to cost approximately $50,000.

Louisiana

MONROE—The Monroe Glass Co., recently organized with a capital of $25,000, has plans under way for the establishment of a new local plant for the manufacture of lamp chimneys and other blown glass products. John Hartman, Alexandria, La., is vice-president.

Maine

MONTAGUE—The International Paper Co., 30 Broad St., New York, N. Y., is reported to be planning for the rebuilding of the portion of its local pulp mill, destroyed by fire Sept. 5, with loss estimated in excess of $50,000.

Maryland

BALTIMORE—The Solarine Co., Emerson Bldg., manufacturer of metal polishes, will take bids at once for the construction of its proposed new 1-story plant, 100x150 ft., on Eagle St., estimated to cost about $75,000, including equipment. E. H. Glidden, American Bldg., is architect.

BALTIMORE — The Baltimore Steel Co., Eastern Ave., has plans under way for the construction of an addition to its plant, on property adjoining the present works, recently acquired, estimated to cost approximately $250,000, including equipment.

BALTIMORE — The Toledo Bottle Cap Co., Toledo, O., manufacturer of paper bottle caps and kindred specialties, has leased space in the Chandler Bldg., comprising about 6,000 sq.ft., and will soon commence the installation of machinery for a new branch plant.

Massachusetts

FITCHBURG—The Crocker Burbank Co., Westminster St., manufacturer of paper products, will commence the immediate construction of a 2-story mill addition, 45x90 ft. The general building contract has been let to Wiley & Foss, Central St.

MALDEN—Wadsworth, Howland & Co., Inc., 139 Federal St., Boston, has awarded a contract to William Daniels, 161 Exchange St., Worcester, Mass., for the construction of a new 5-story building, 52x190 ft., at Malden, to be used in connection with its general line of paint and varnish manufacture.

SALEM—Baker & Kimball, 28 South St., Boston, have acquired property at 5 Fort Ave., Salem, 70x175 ft., and have plans in preparation for the construction of a 2-story plant on the site, to be used for the manufacture of leather products.

Michigan

KALAMAZOO—The Bryant Paper Co. has plans under way for the construction of two new plant buildings, and enlargement of a number of plant departments for considerable increase in production. The work will include a 1-story machine shop, and new power plant. A bond issue of $5,000,000 is being arranged, a portion of the fund to be used for the expansion.

New Jersey

OLD BRIDGE—The Ceramics Products Corp., recently organized with a capital of $200,000, has acquired the local plant of the Brookfield Glass Co., comprising a number of buildings on a tract of 150 acres of land, with considerable equipment previously used by the former owner, for glass and pottery manufacture. Plans are under way for a number of improvements in the plant, and operations will be commenced at an early date, giving employment to about 200 persons. The new company is headed by Gerald M. McLaughlin and T. Bryant Smith.

LAMBERTVILLE—The Lambertville Rubber Co. is planning for enlargements in its plant, to include the establishment of a new department for the manufacture of different rubber specialties. It is purposed to increase the working force by about 50 operatives.

TRENTON—The Economy Pottery Co., Bunting Ave., manufacturer of sanitary earthenware, has filed plans for the construction of a 1-story addition.

BAYONNE — The Standard Oil Co., 26 Broadway, New York, N. Y., has commenced excavations for the construction of a new 3-story building, 80x100 ft., at its local oil works, estimated to cost about $75,000.

TRENTON—The Murray Rubber Co. is being organized to take over and operate the plant of the Empire Tire & Rubber Corp., North Clinton and Mulberry Sts., recently acquired at a receiver's sale by William M. Pepper and associates for a consideration of $1,675,000. The new company plans for the immediate resumption of operations at the plant, and will soon commence the installation of machinery for enlargements in a number of departments. C. Edward Murray, Jr., is president and general manager. Mr. Pepper is vice-president and treasurer.

TRENTON—Fire, Sept. 19, damaged a portion of the plant of the Mercer Pottery Co., Muirhead Ave., manufacturer of chinaware products. The loss, including power plant and damage to the main 4-story pottery, has not been officially estimated.

New York

NORTH HOOSICK—The Stevens & Thompson Paper Co., operating a local mill, with branch plants at Walloomsac and Greenwich, N. Y., will make enlargements at the two last noted mills to increase the capacity from 85 to 100 tons per day. The company is also arranging for extensive operations at the plant of a subsidiary organization at Bloomfield, N. J. To provide for the expansion, a bond issue of $1,000,000 has been arranged. Frank L. Stevens is president.

ROCHESTER—The Don-o-Lac Co., manufacturer of paints, varnishes, etc., is considering the rebuilding of the portion of its local plant, destroyed by fire, Sept. 18 with loss estimated at about $60,000.

NEW YORK—The Braden Copper Co., 120 Broadway, is arranging an appropriation of $1,500,000 for the construction of an addition to its copper mill, to increase the capacity from 10,000 to 15,000 tons of ore per day. The company is a subsidiary of the Kennecott Copper Corp., same address.

North Carolina

GREENSBORO—City Manager P. C. Painter is taking bids until Oct. 10 for the construction of a new filtration plant with capacity of 6,000,000 gal. The Ludlow Engineers, Inc., Winston-Salem, N. C., is engineer.

HILTON—Fire, Sept 18, destroyed a portion of the acid works of the American Cotton Oil Co., with loss estimated at about $25,000. It is planned to rebuild.

Ohio

LANCASTER—The Fairfield Glass Co., manufacturer of window glass, has plans nearing completion for the construction of a new plant, to consist of a number of buildings, estimated to cost close to $2,500,000, including machinery. The De Vore Co., 908 Nicholas Bldg., Toledo, O., is architect and engineer. Leopold Mambourg is vice-president and general manager.

MINERVA—The Owen China Co. has awarded a general contract to W. A. Rabold, 804 Columbus Ave., N. W., Canton, O., for the construction of a new 1-story pottery, on local site, 165x190 ft., estimated to cost approximately $175,000, including equipment. C. W. Foreman is president.

Oklahoma

OKLAHOMA CITY—The North American Oil Co., recently organized under Delaware laws with capital of $35,000,000, has tentative plans under consideration for extensions and improvements in the oil refineries of a number of companies lately consolidated. The properties of the new company include the Noco Petroleum Co., the Noco Mexican Oil Co. and the Noco Pipe Line Co., all of Oklahoma City; the Black Petroleum Corp., Okmulgee, Okla.; the Puritan Petroleum Co., Lesh Refining Corp., Lesh Oil Products Co. and the Petroleum Transit Co. all of New York. C. F. Colhord heads the new organization.

OKLAHOMA CITY—The Golthorpe Oil Refining Co., including refinery and equipment, has been acquired by George Smith and associates. The new owners plan for enlargements and improvements in the plant, to include the installation of additional equipment.

Pennsylvania

BOYERTOWN—The Eastern Foundry Co. will soon take bids for the construction of a new 1- and 2-story foundry addition, 100x150 ft. A. S. Keptner, 121 Hanover St., Pottstown, Pa., is architect. E. M. Rhoads is president of the company.

KUTZTOWN—The Reading Rubber Co., Reading, Pa., has acquired the local plant of Jacob K. Boyer, heretofore devoted to box manufacturing, and will remodel and improve the works for the establishment of a new plant for the manufacture of rubber tubes for automobile service. Machinery to cost close to $25,000, will be installed.

PHILADELPHIA—The West Philadelphia Cut Glass Co., 5920 Baltimore St., has taken bids and will soon commence the construction of a new plant at Redfield and Baltimore Sts. Emile G. Perrot, Boyertown Bldg., is architect.

PITTSBURGH—The Hanlon-Gregory Galvanizing Co., 24th St. and the Alleghany Valley Railroad, is completing plans for the construction of a new 1-story plant at 56th and Butler Sts., 100x400 ft., to be used for the manufacture of galvanized metal products. It will cost about $100,000. J. R. Dwyer, Forbes-Murray Bldg., is architect.

HARRISBURG—The Rocbond Co., VanWert, O., manufacturer of cement-stucco products, has work under way on a new plant at

ucknow, near Harrisburg. It will be 1-ory, 50x300 ft. H. S. Webster and O. E. hompson, formerly located at the VanWert lant, will be in charge at the new local orks.

PITTSBURGH—The Ball Chemical Co., Ful-on Bldg., has awarded a contract to the Villiams & Haas Co., Empire Bldg., for the onstruction of a new building at Whitmar tation, to cost about $25,000.

Texas

PORT ARTHUR—The Gulf Refining Co. has reliminary negotiations under way for the urchase of a tract of about 100 acres of and, to be used as a site for the construc-ion of an addition to its local refinery. The ew plant will operate under an aluminum hloride process of gasoline separation from rude oil, and is estimated to cost close to 500,000. George H. Tabor is vice-presi-lent.

DAMON—The Union Sulphur Co., Sulphur, a., has acquired a tract of local land, com-rising about 215 acres, to be used as a site or the construction of a new plant. The works will consist of a number of buildings, ncluding machine shop, power house, etc., nd will be supplemented with a housing levelopment for employees. It is expected o require close to 24 months for the com-letion, with estimated cost close to $5,000,-000.

DALLAS—The Southwestern Paper Co. is ompleting plans and will soon commence he construction of a new building on Lacy St. near Young St. George L. Thompkins s general manager.

GALVESTON—The Galveston Gas Co. will uild an addition to its artificial gas plant at 32nd St. and Ave. D, estimated to cost close to $100,000. It will have a capacity of 100,000 cu.ft. per hour. Paul E. Nichol is general manager.

DALLAS—The Garvey Vinegar Co. has plans in preparation for the establishment of a new local plant for the manufacture of vinegar products, with initial capacity of about 25,000 gal. per month. Thomas Gar-vey is head.

West Virginia

WHEELING—The Wheeling Mantle & Tile Co., 829 Market St., has awarded a gen-eral contract to George A. Reed, Wheeling, for the construction of a new 1-story plant, estimated to cost about $15,000.

WHEELING—A 1-story foundry, 100x320 ft., estimated to cost about $40,000, will be constructed on Warwood Ave., by the Centre Foundry & Machine Co., 2011 Main St., estimated to cost about $40,000. It will be used for the production of steel castings. The general contract has been let to the Riverside Bridge Co., Martins Ferry, O. J. H. Young is general manager.

Industrial Developments

GLASS—The Ruth-Hastings Glass Co., Conshohocken, Pa., manufacturer of bottles, vials and other hollow ware, is arranging for the immediate resumption of operations at its plant, after an idleness of more than 2 years.

The Twin City Glass Co., Texarkana, Tex., manufacturer of blown glass ware, has resumed operations at is local plant, following a curtailment for some time past. Employment will be given to about 300 men. A wage increase of 5 per cent has recently been granted.

The Elk Run Window Glass Co., Punxsutawney, Pa., has resumed operatons at its local plant, after a shut-down for several months past.

The F. L. Freas Glass Works, Conshohocken, Pa., specializing in the production of chemists' glassware and kindred glass products, is running full at its local plant, giving employment to the regular working force. The company is said to have orders on hand for considerable advanced production.

T. C. Weaton & Co., Millville, N. J., have resumed operations at one of their bottle plants, following a shut-down of about 6 weeks.

The Whitall-Tatum Co. has commenced production at two glass plants at its South Millville, N. J. works, following a suspension of several weeks past.

The Noble Glass Co., Conshohocken, Pa., manufacturer of small bottles, vials, etc., is operating at regular capacity with normal working force, and is said to have orders on hand to insure this basis of production for some time to come.

The Millville Bottle Works, Inc., Millville, N. J., has resumed operations at one of its furnaces, following a suspension for more than a month past.

LEATHER—The Pearse Leather Corp., Peabody, Mass., has adopted a full-capacity working schedule at its local tannery, with an overtime shift in a number of departments.

The General Leather Co., Newark, N. J., is operating at full capacity for the production of leather for automobile service, and is said to have orders on hand to insure this basis of production for an indefinite period.

V. & F. W. Filoon & Co., Brockton, Mass., has inaugurated an overtime working schedule at its local tanneries, averaging about 4 hours a day.

The DeFord Co., Baltimore, Md., is operating at full capacity at its leather tanneary at Luray, Va. The Covington, Va., plant of the company is said to be running on a curtailed basis, with plans to advance production at an early date.

The Empire Tanning Co., Big Run, near DuBois, Pa., is arranging to close its local plant early in October for an indefinite period. It has been operating on a half-time working basis for a number of months past, and orders on hand will be transferred to other plants of the company. The tannery has been giving employment to about 80 men.

The Fred Rueping Leather Co., Fond du Lac, Wis., is operating at full capacity, giving employment to a regular working force.

J. S. Barnett & Sons, Inc., Lynn, Mass., has adopted a capacity schedule at its local tannery, with employment of normal working force.

PAPER—The D. M. Bare Paper Co., Altoona, Pa., is running at full capacity at its mills at Roaring Springs, near Altoona, giving employment to about 400 operatives. A wage advance of 25 cents a day has been placed into effect.

The Belgo-Canadian Paper Co., Shawinigan, Que., is operating at full capacity at its local paper mills, with employment of maximum working force. The company has plans in progress to double the capacity of the present plant.

The Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis., is running full at its local paper mills. A wage advance of 10 per cent, averaging from 3 to 5 cents an hour has recently been granted.

IRON AND STEEL—The American Swedo Iron Co., Danville, Pa., has resumed operations at its local plant, following an idleness for a number of months past. The plant will give employment to about 75 men under full production. The company is said to have orders on hand for about six months to come.

The Punxsutawney Furnace Co., Punxsutawney, Pa., has commenced production at its local plant, following a suspension of operations for more than a year and a half past. It is planned to employ a full working force for an indefinite period.

The Bethlehem Steel Corp. is arranging for the immediate resumption at its Reading, Pa., rolling mill, which has been idle since early in 1921. The works will give employment to about 100 men for initial production, and this number will be increased gradually until a full working force is reached.

The Jones & Laughlin Steel Co., Pittsburgh, Pa., is advancing production at its blast furnaces, and is now running at 75 per cent of normal.

The Struthers Furnace Co., Struthers, O., will blow in its local blast furnace at once, after a suspension of operations for about 20 months past.

The American Sheet & Tin Plate Co., Farrell, Pa., is developing capacity production at its local sheet mill for the first time in a number of weeks past. Arrangements are being perfected for the resumption of operations at the Aetna Standard plant at Pittsburgh, Pa. The company is advancing production at its Sharon, Pa., works, and has recently advanced wages 10 per cent at this plant.

The Illinois Steel Co., Chicago, Ill., has increased production to about 65 per cent of capacity at its mills, and plans for a further advance at an early date.

The Tennessee Coal, Iron & Railroad Co., Birmingham, Ala., is arranging to blow in its No. 1 blast furnace within the next few weeks, making ten furnaces in service at the Alabama mills of the company. The No. 1 unit has a capacity of 550 tons per day.

The Hanna Furnace Co. has arranged for the blowing in of its blast furnace at Dover, O., following a suspension since last August. Employment will be given to about 100 men.

The Lockhart Iron & Steel Co. of Pittsburgh has started operations at the recently acquired plant of the Sligo Iron & Steel Co. at Connellsville, Pa. The plant has been reconstructed and furnished with up-to-date equipment for the production of muck bars, which will be shipped to the McKees Rocks plant for finishing. Twenty puddling furnaces are now operating, with a capacity of 22,000 tons a year. The plant employs 100 puddlers.

MISCELLANEOUS—The Keystone Tire & Rubber Co. has placed its new plant unit at Kingsbridge, N. Y., in operation on a full-capacity basis.

The Lee Tire & Rubber Co., Conshohocken, Pa., has advanced production at its plant, and is now running on a full day and night schedule.

The Austin Mfg. Co., Wilkes-Barre, Pa., recently organized to manufacture chemical products, has opened a local plant and will operate on a full capacity basis for an indefinite period.

The St. Louis Coke & Chemical Co., a subsidiary of the National Enameling & Stamping Co., is operating its battery of 80 process coke ovens at Granite City, Ill., at full capacity. The parent organization has resumed operations at 14 additional sheet mills at its local plant, and all departments are now running full.

New Companies

THE B. C. TILLINGHAST RUBBER MFG. CO., Jersey City, N. J., care of the Corporation Trust Co., 15 Exchange Place, representative, has been incorporated with a capital of $50,000, to manufacture rubber products. The principal incorporator is B. C. Tillinghast.

THE ANGELES SNOWOLENE REFINING CO., Los Angeles, Calif., care of G. A. McElroy, 510 West 6th St., representative, has been incorporated with a capital of $200,000, to manufacture refined petroleum products. The incorporators are F. E. Snowden, W. P. Rhodes and K. M. Dean, all of Los Angeles.

THE C. L. SANFORD BRICK CO., Southold (Suffolk County), N. Y., care of G. C. Terry, Southold, representative, has been incorporated with a capital of $60,000, to manufacture brick and other burned clay products. The incorporators are C. L., L. N. and F. S. Sanford.

THE CLASON CHEMICAL CORP., Brooklyn, N. Y., care of the Delaware Registration & Incorporators' Co., Ford Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $1,000,000, to manufacture chemicals and chemical byproducts. The incorporators are Marcus Bassell and Samuel Zimmerman, both of New York.

THE ALUMINUM PRODUCTS CO., Boston, Mass., has been incorporated with a capital of $25,000, to manufacture aluminum and kindred metal products. Ralph L. Dodge is president, and John A. Carpenter, 6 Brigham Ave., Waverly, Mass., treasurer. The last noted represents the company.

THE ENAMELING MFG. CO., 549 West Fulton St., Chicago, Ill., has been incorporated with a capital of $15,000, to manufacture enamelware products. The incorporators are James D. White, Edward R. Mills and Herbert C. Moore.

THE REDWOOD OIL & REFINING CO., Cross Plains, Tex., has been incorporated with a capital of $250,000, to manufacture refined petroleum products. The incorporators are C. T. Pledger, J. H. Montgomery and R. B. Forbes.

THE UTILITY COLOR & CHEMICAL CO., Newark, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and affiliated products. The incorporators are M. M. Williams, Jacob S. Lasky and Louis Schneider, Kinney Bldg., Newark. The last noted represents the company.

THE ATHENIA CHEMICAL CO., Hartford, Conn., has been incorporated with a capital of $50,000, to manufacture chemicals and chemical byproducts. The incorporators are George Drossinos and Henry Brenner, 150 Governor St., Hartford.

THE INTER-CONTINENT OIL CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $5,000,000, to manufacture petroleum products.

THE RUMO CHEMICAL CO., New York, N. Y., care of M. G. Cutler, 42 West 39th St., representative, has been incorporated with a capital of $5,000, to manufacture chemicals and kindred products. The incorporators are P. Trachtenberg, G. Rosenberg and D. W. Gregory.

THE MIDDLESEX REFINING CO., Middletown, Conn., has been incorporated with a

capital of $50,000, to manufacture soaps, fat byproducts and kindred specialties. The incorporators are S. S. and Jacob Mattes, 151 Church St., Middletown.

THE BRIGHTON ELECTRIC STEEL CASTING Co., Beaver Falls, Pa., has been incorporated with a capital of $25,000, to manufacture steel and other metal castings. The incorporators are W. D. Fox, New Brighton, Pa.; Fred Dewhirst and Earl D. Townsend, Beaver Falls. The last noted is treasurer and represents the company.

THE AMERICAN CHEMICAL GAS Co., Philadelphia, Pa., care of the Corporation Guarantee & Trust Co., Land Title Bldg., representative, has been incorporated with a capital of $1,500,000, to manufacture special chemicals and chemical byproducts.

THE SUPERIOR PORCELAIN PRODUCTS Co., 138 North La Salle St., Chicago, Ill., has been incorporated with a capital of $5,000, to manufacture porcelain specialties and kindred ceramic products. The incorporators are G. J. David and James H. Davis.

THE CRYSTAL PRODUCTS CORP., Newark, N. J., care of David N. Popik, 790 Broad St., representative, has been incorporated with a capital of $50,000, to manufacture chemicals, alkalies, etc. The incorporators are Karl J. and Bernard W. Von Smuda, and Abraham Shapiro.

THE METHOLAM PRODUCTS CORP., Brooklyn, N. Y., care of Maxwell Lustig, 154 Nassau St., New York, N. Y., representative, has been incorporated with a capital of $50,000, to manufacture chemicals and affiliated products. The incorporators are V. P. Mehta, J. O. Olsen and C. G. Dutemple.

THE CONSOLIDATED BRICK Co., Melrose, Mass., has been incorporated with a capital of $98,000, to manufacture brick and other burned clay products. George L. Baldwin is president, and James E. Fraser, 24 Natalie Ave., treasurer. The last noted represents the company.

THE GENERAL TESTING LABORATORIES, INC., 525 Woodward Ave., Detroit, Mich., has been incorporated with a capital of $6,000, to manufacture chemicals, chemical compounds, etc. The incorporators are Paul H. Kramer, Charles L. Mann and Joseph A. Wolf.

THE CHINA FIBRE CONTAINER Co., care of the Corporation Trust Co. of America, due Pont Bldg., Wilmington, Del., has been incorporated under Delaware laws with capital of $250,000, to manufacture fiber products.

THE DAYTON BRICK Co., Dayton, O., has been incorporated with a capital of $200,000, to manufacture brick and other burned clay products. The incorporators are Lincoln L. Davis and John M. Mulford, both of Dayton.

THE POMPTON IRON Co., 745 East 23rd St., Paterson, N. J., has been incorporated with a capital of $250,000, to manufacture pig iron. It is proposed to operate a blast furnace in the state. The incorporators are Halsey M. Search, J. Fred Weller and Arthur Searck.

THE HAMILTON INTERNATIONAL PULP & LUMBER Co., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, has been incorporated under Delaware laws with capital of $2,500,000, to manufacture pulp and paper products.

THE PEAVEY RUBBER Co. OF NEW ENGLAND, Boston, Mass., has been incorporated with a capital of $40,000, to manufacture and deal in rubber products. Ralph A. Peavey is president and treasurer, 101 Homer St., Newton, Mass.

THE NATIONAL OIL Co., Long Beach, Cal., care of Guy F. Rice, Ocean Park, Cal., representative, has been incorporated with a capital of $250,000, to manufacture petroleum products. The incorporators are F. N. and J. L. F. Cosby, and Paul J. Wessel, Long Beach.

THE NEW JERSEY METAL SALTS Co., Bayway and South Front Sts., Elizabeth, N. J., has been incorporated with a capital of 200 shares of stock, no par value, to manufacture metal salts, chemical specialties, etc. The incorporators are J. Alvin Van Bergh, Donald C. Strachan and Albert L. Fiorillo.

THE TENNESSEE CHEMICAL Co., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with a capital of $1,000,000, to manufacture chemicals and chemical byproducts.

THE ATHENS OIL Co., Athens, Tex., has been incorporated with a capital of $100,000, to manufacture petroleum products. The incorporators are J. F. Gilmore, W. G. Crumpler and J. M. Hardaway, all of Athens. The same incorporators have also organized the Kaufman Oil Co., Kaufman, Tex., with like capitalization, to manufacture a similar line of products.

Industrial Notes

A. DAIGGER & Co. announce that an erroneous report has been circulated regarding a fire which started on their premises at 54 E. Kinzie St., Chicago, Ill. The fire referred to occurred in the block in which the premises of A. Daigger & Co. are located, but no damage occurred to the property of A. Daigger & Co., who were fortunately spared any suffering on this account. They are doing business without any interruption whatsoever and are in excellent position to give immediate, efficient and satisfactory service.

JOHNS-MANVILLE, INC., in order to afford better service to clients, has been appointed joint selling agent by the H. H. Robertson Co. In the future all asbestos-protected metal roofing, siding, accessories and ventilators will be manufactured and shipped from the plant of the H. H. Robertson Co. at Ambridge, near Pittsburgh, Pa. Hereafter, in the manufacture of asbestos-protected metal produced by the H. H. Robertson Co., Johns-Manville asbestos saturated felts will be used, thus affording to the customer both the advantages of the experience of Johns-Manville, Inc., in the manufacture of saturated asbestos felts and the experience of the H. H. Robertson Co. in the fabricating to the finished product.

THE AMERICAN AGRICULTURAL CHEMICAL Co., New York City, at a recent directors' meeting, elected the following officers: Chairman of the board, Robert S. Bradley; president, George B. Burton; vice-presidents, Royall Vistor, Horace Bowker and J. D. C. Bradley; treasurer, Arthur P. Stemm; secretary, J. A. Starrett.

THE BROWN INSTRUMENT Co., Philadelphia, Pa., announces the opening of a Southern branch at 619 Brown-Marx Bldg., Birmingham, Ala., in charge of Charles L. Saunders, and a New England branch at 185 Devonshire St., Boston, Mass., in charge of George Goodman.

M. F. KING, formerly of the Kings Refractories Co., has joined the sales and service department of the Quigley Furnace Specialties Co. Mr. King brings to the Quigley organization the benefit of his wide experience in the application of refractories and high-temperature cements and will devote his attention to service and sales work in New York City.

THE POWER SPECIALTY Co., New York, announces the appointment of Pell W. Foster, Jr., as New England district manager, with offices at 50 Congress St., Boston. Mr. Foster was formerly in the New York sales office.

THE MUELLER ELECTRIC Co. announces the completion of its new building at 1583 East 31st St., Cleveland, where it will continue in a larger way to manufacture electric specialties.

THE CHICAGO FLEXIBLE SHAFT Co. has opened a new district sales office with headquarters in Indianapolis for the handling of furnace sales and Stewart engineering service in southern Indiana, southern Ohio and western West Virginia. F. W. Odemar is in charge of this office and the address is 305 Merchants Bank Bldg.

THE H. K. FERGUSON Co., engineer and builder, Cleveland, O., has elected Jos. S. Ruble vice-president in charge of all construction. Mr. Ruble resigned recently as vice-president of the Austin Co., which position he has held for the past 9 years.

Manufacturers' Catalogs

THE ALLIS-CHALMERS MFG. Co., Milwaukee, Wis., in Bulletin 1821, illustrates and describes Rod Mills.

THE YARNELL-WARING Co., Philadelphia, Pa., has published Bulletin T-1701, describing Yarway steam traps recently developed and placed on the market.

THE LEWIS SEARING Co. OF MICHIGAN, Detroit, Mich., has issued a booklet on "Eight Common Grease Cup Troubles Eliminated."

THE REDMANOL CHEMICAL PRODUCTS Co., Chicago, Ill., has issued an attractive booklet, descriptive of Redmanol products. The booklet tells what Redmanol is, its strength, list of products made from Redmanol, how to mold, etc.

THE ARMSTRONG MACHINE WORKS, Three Rivers, Mich., has published a booklet—Catalog C—on "Armstrong Steam Trap," which gives a description of the operation, application and construction of the traps.

THE ZELLER LACQUER MFG., Co., New York City, has published a booklet, "250 Lacquer Questions Answered," which it is distributing to all who write for it on business stationery, or otherwise identify themselves. This is the first time that anything of this comprehensive nature has been published. It is presented in question and answer form, practically every problem confronting the lacquer user being answered.

THE PHILADELPHIA GEAR WORKS, Philadelphia, Pa., has issued a catalog and price list which shows an increase in the company's standard stock gears and a still greater increase in its facilities for making gears.

THE ESTERLINE-ANGUS Co., Indianapolis Ind., has issued Bulletin 722, on the graphic wattmeter.

THE U. S. GALVANIZING & PLATING EQUIPMENT CORP., Brooklyn, N. Y., has issued newly revised bulletins on U. S. Moving Cathode Plating Apparatus (for plating or electrogalvanizing) and U. S. Automatic Cleaning, Pickling, Acid Dip Neutralizing, Rinsing, Drying and Allied Equipment, Bulletins 100 and 105, respectively.

THE VINELAND SCIENTIFIC GLASS Co., Vineland, N. J., has issued a booklet on Glassware Facts, including machine made homeopathic vials, ampoules, radio tubes (for crystal detector sets), oil cup glasses and test tubes.

THE ARMSTRONG CORK & INSULATION Co., Pittsburgh, Pa., has issued a small folder on "A Neglected Source of Economy," which deals with the savings that can be effected in manufacturing plants by the use of refrigerated drinking water systems.

THE DURIRON Co., INC., Dayton, O., calls attention to Bulletin 128-A, just issued describing the latest Duriron centrifugal pump Series 102.

Coming Meetings and Events

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

AMERICAN SOCIETY FOR STEEL TREATING is holding its International Steel Exposition and Convention in the General Motors Bldg., Detroit, Mich., Oct. 2 to 7.

AMERICAN WELDING SOCIETY is holding its fall meeting Oct. 2 to 5 at Chicago.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month. The first meeting of the fall season will be held on Oct. 9.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will hold its fall meeting Oct. 9 and 10, at the Hotel Wolverine, Detroit, Mich.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, 52 East 41st St., New York City: Oct. 6—American Chemical Society, regular meeting Oct. 13—Société de Chimie Industrielle, regular meeting. Oct. 20—Society of Chemical Industry, Grasselli Medal. Nov. 10—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting. Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting, May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

A Forward Movement in Chemical Engineering Education

THE announcement printed in our news pages of this week that the American Institute of Chemical Engineers has appointed its committee on chemical engineering education records a step that is worthy of more than passing attention.

The tremendous success and widespread interest in the conference which was held last spring under the auspices of the Institute showed that the field was ripe for active endeavor. The able and comprehensive report which was the basis of discussion at this conference, presented by the chairman of the retiring committee, Dr. A. D. LITTLE, of Boston, contained a complete survey of the field and indicated the points on which there must be marked activity in the future. The next step was the indorsement of the report by the Institute at its Niagara Falls meeting in June and the authorization for a committee of the Institute to carry on this work and, within three years, announce a classification of the chemical engineering courses of the country, approving those deserving commendation.

The committee has now been appointed, five members being from industry and five from educational instiitions. The personnel is distinguished not only by service to industry and to education but by a soundness of ideas on this important subject and a rationally progressive attitude which augurs well for the success of the work.

"It Pays To Advertise"

ADVERTISING MEN can argue quite convincingly that anything can be sold if it is properly advertised. And there is one phase of this doctrine that should appeal particularly to technical men. It is the presentation of technical facts through the advertising pages of the daily and popular press.

It is getting to be quite the proper thing to appeal to the reader through advertising on the ground that the quality of the product advertised is maintained by very careful laboratory and plant supervision. Not infrequently the name is given of the laboratory investigator making marked achievement, and the advertiser almost invariably makes haste to stress his superiority of product when he establishes a new control method or when his research department has developed new information of interest to the user of the product.

This tendency to utilize technical achievement as a basis for publicity work should be taken into account by directors of research and chief chemists. When new work of importance is developed, the possibility of gaining advantage for their companies through judicious publicity should be recognized. Very often the laboratory investigator or the chemical engineer will be the first to recognize these possibilities and it then becomes his responsibility to bring them to the attention of the proper officials. A technical story clearly and simply but convincingly told in an advertisement in the daily press should be helpful to all concerned.

Preaching And Practice

TWO eminent army officers, Generals PERSHING and HARBORD, speaking at the first convention of the Reserve Officers' Association, have stressed the same point—that it is false economy excessively to curtail military preparation in peace time. General PERSHING in stressing this point uses the following language: "It would be false economy to save a few dollars by neglecting common-sense preparation in peace time and then to spend billions to make up the deficiency when war comes." General HARBORD lays greater emphasis upon the intimate association between those responsible for the management of military affairs and those whom he characterizes as "stockholders" in the business. The doctrine advanced by these officers is sound and would meet with almost universal agreement, but it is unfortunate that the practice of the army, particularly the theory upon which General PERSHING has administered army affairs, does not accord with the doctrine which he advocates.

If there is any branch of military activity in which preparation in time of peace and training of an organization nucleus is required, it is in the field of chemical warfare. In this particular field it has seemed to be a hobby of the Chief of Staff to discourage any progressive thinking or constructive effort. He, more than any other individual in the world, is responsible for the rather abortive effort made in the treaty preventing the promiscuous use of poison gas. In that field the conclusion which he has advocated has been illogical.

It is idle now to argue whether the treaty should have been adopted in the form and phrasing which was approved. But it is still entirely reasonable to insist that the preparation and training of men in the modern methods of warfare through use of chemical weapons must go forward if any degree of security is to be had. Troops put in the field must know how to defend themselves against gas attack, for if there be any conflict of consequence it is certain that some forms of chemical warfare will very promptly be used. Moreover, there should be the nucleus of an offensive chemical warfare service thoroughly trained to handle all the problems involved in preparation, transportation and projection of war chemicals. Especially is it essential that work on tear gases, sneeze gases and the other non-toxic weapons be thoroughly developed.

While the Chief of Staff and the Deputy Chief of

Staff are pleading with reserve officers on behalf of preparedness, it would be well if they think through the problems of chemical warfare again. If they will carefully consider all aspects of the case, they cannot fail to realize that this branch of the service has been sadly handicapped during the last year or two. In fact, were it not for the much broader, better vision of the Naval Staff our Chemical Warfare Service would be practically out of business at present.

During the coming sessions of Congress it will be appropriate that General PERSHING and his principal deputies lend a much-belated support to adequate appropriations for this work. An extra million dollars a year in this field will maintain effective research and development; and if ever again we suffer from serious war, this small expenditure will represent insurance having face value in the billions. May we not hope that the practice of high army officers will agree in the future more closely with the preaching than it seems to have done in the past?

Anecdotes of Old Galchester

WHEN chemists get into high finance, the bell should ring. There were Derby and Darby and Durby and Dorby of Galchester who made, let us say, dubium oxide, dubium chloride and a series of widely used dubium compounds. Each one was in business for himself, each was rich, possibly a little vain, as becomes the habit of rich men, but they were a pretty good sort, every one of them; and every one proud of his reputation as a citizen and a manufacturer. Their friendship was an asset, especially to their customers; for when bad times came around they did their best to see their old customers through, while if markets got crazy and prices went up in the air, they stuck to their contracts, fulfilling them exactly as agreed. They would even renew them in seasons of great prosperity at the lowest figures they could profitably make. Each one was jealous of his good will, and resolved to maintain it at any cost. They were also good friends.

Off in one corner of the county was Digby who had dubium interests, and Derby thought it would be a good thing to buy him out. He therefore proposed joint action to his friends Darby, Durby and Dorby, who agreed, and negotiations were begun. They bid 5, and Digby asked 10, but finally they compromised on 9. Digby proved to have more dubium interests than they had reckoned on, so in order to swing the deal they called on Mr. Quickturn Capital, who asked them questions about their own business. He was interested, having already picked up "a few blocks of stock" in the dubium industry.

Mr. Capital was amazed. He was also shocked. But he said he would come into the deal and help them out. He offered to put up $5 in cash and to give his note for $2.50 more for each of Digby's dubium units and to let the other gentlemen put up $1.50 more, to make up the price; but this was with the proviso that they give him one-quarter of the profits on the transaction. To this they agreed. Digby said if they were to give notes he wanted $9.50, and Mr. Capital surprised his associates by his quick decision. He was above bargaining.

"Let it be $9.50," said he, "and we will make one note for the whole amount. You gentlemen can indorse it, and I'll put my name on last and guarantee you."

To this all agreed, and a note for the large sum was made to Digby and indorsed by Derby, Darby, Durby and Dorby. Then Mr. Capital wrote underneath: "In case any or all of the above indorsers should default on this note, I agree to make good such default. Quickturn Capital." Digby turned over his papers; Capital handed him the note.

"I've always remarked," said Mr. Capital, "that you chemists are children in business. You're soft. You neglect your opportunities. Business is business; it isn't a tea-party. You have foolish ideas about good will, and you sell dubium at a price way below the market to your so-called customers—and let them reap the profits. Business is business, I repeat, and its purpose is to make profits. You people don't know how to keep books, and you don't know anything about markets or how to control them. In fact, you're little children. This incident of the note is an example of how slow you are at trading. You're way behind the times. This whole trade is a mere bagatelle. We'll sell this Digby dubium at 25, but that is nothing to what we can make. I think I shall have to take a hand in your affairs and look into the dubium market."

He proceeded to do so while the others lost their breath once more and caught it again. Then followed weeping and wailing and gnashing of teeth, but there rolled in such a flood of golden money that, according to the legend, Derby and Darby and Durby were comforted. But Dorby retired because the cries smote his ears and caused him great distress. Dorby comforted himself with apples.

Long Range Price Trends

WE HAVE all been very much interested, since the armistice, in commodity prices. The interest has not been merely the selfish one involving the question of what we could get for such dollars as we ourselves had. Prices have furnished an index to economic conditions, in which we all have a general interest.

When, just after the armistice, prices displayed a greater reluctance to decline than had commonly been expected, we wondered whether this meant that the value of the dollar had been permanently depreciated. Some observers insisted that such was the case, citing the large increases in the currencies of various countries together with the large issues of government bonds. If so, the real value of all bonds and mortgages had been greatly depreciated, while at the same time it would be justifiable to mark up the value of all real estate, plants, etc.

In the great price rise of the latter part of 1919 and the early part of 1920 the common view was that the particularly high prices represented a deficiency in production, the assigned reason being that men were not working hard enough. With the declines of 1921 we concluded that men were working harder and manufacturers and dealers were contenting themselves, perforce, with smaller profits. More recently prices have been advancing again, and most people are talking about "secondary inflation."

We have got into the way of making practically all price comparisons by using the 1913 average as standard. Undoubtedly it was necessary to adopt a standard, and the calendar year before the war seemed the natural year to take. The point that it is desired here to emphasize is that we are certain to make serious mistakes if we consider 1913 a perfect standard, with which all current prices may properly be compared. The easy concept must be avoided that 1913 was really

typical, while furthermore we must not overlook the fact that in nine years many conditions would have changed had there been no war and no inflation. All commodities would not now be at the same level as in 1913, or 25 per cent above or 25 per cent below. Some would be higher, some would be lower, and even the general average would not be the same.

The Department of Labor has just issued "Wholesale Prices, 1890 to 1920." this being the eighteenth of a series, begun in 1902. The last bulletin of similar character was published in 1916. Meanwhile there has been a change in the system whereby the relative to 1913 is given for each of many commodities or groups, for each year beginning with 1890. Thus a fresh and valuable means of comparison is now afforded.

In order to judge rightly the significance of a given comparison, that the commodity is 125 or 150 or 175, relative to 1913, we need to consider how the commodity in 1913 compared with prices in previous years. The commodity may have been falling up to 1913 and in that case it is particularly remarkable if now it is much above 1913. It may have been advancing up to 1913, in which case a further advance is not remarkable. At this late date we cannot hold that because one commodity is 150 relative to 1913 another commodity should likewise show a relative of 150.

To illustrate, one finds that, with 1913 prices as 100, carpets were at their highest in that year, having been 80 in 1890, 70 in 1895 and 1896 and 92 to 93 in 1909, 1910 and 1911. Wheat, on the other hand, was 101 in 1891, 63 in 1893 and 126 in 1909. Thus it would be much more remarkable for wheat than carpet to have a high relative to 1913 at the present time. Again, compare brick and plate glass. Brick was 100 in 1890, 75 in 1897 and 130 in 1906. Its 1913 price was therefore quite typical of the average for a period of years. Plate glass, on the other hand, was 180 in 1890, 139 in 1900 and of course 100 in 1913. Thus it had been experiencing a great decline. In no year from 1890 on were matches as cheap as in 1913, while in none of those years were kitchen tables as dear.

Views on University Research

IT IS a matter of common remark that "experts disagree." Men of approximately the same education and environment often develop wide differences in view on questions of common interest. But it is worthy of notice when leading educators start from the same premise, defining the proper aim of education, and finish with entirely different proposals as to how that destiny can be met. Particularly is this true when both of them were formerly associated as deans in the same university.

They both recognize that the university must be something more than a storehouse, where the sum of human knowledge is iced away and preserved. Furthermore, the university must be of use to a far wider public than the favored students who are fortunate enough to attend its classes. And they are further in agreement that the university faculty should be investigators as well as instructors. In short, they recognize that a modern university has grown beyond the ambitions of its predecessors. Indeed, the end of the dark ages and the revival of learning were both foreshadowed by the determination of educated men to push out into the unknown and discover more facts to add to the accumulated store.

But that's about as far as these two scholars agree. A modern university, says one, should have as its "chief objective the development of knowledge, while instruction becomes incidental." By no means, says the other, "Scientific research and the advancement of knowledge should be in a position of equal importance with the work of instruction." An even wider difference of opinion exists on the methods of research. The former says, "The faculty becomes a body of real scholars who will exert all their powers toward discovering new facts and setting them into their proper places with related facts in order that principles may be brought to light—a great process of critical analysis and synthesis, with logical deduction which we call research." But the second educator holds that "the solution of the problems of most industries can best and most economically be undertaken through association with the universities and technical schools," and further in his address argues the thesis that the faculty should devote their time not pre-empted by the class room to the solution of troubles cropping up here and there in the industries.

We venture to disagree with both these conclusions.

From an engineer's point of view it is essential that the universities keep *instruction* as their great work—instruction of matriculated students and instruction of the far greater public outside the cloistered walls. An institution which does not pay first attention to instruction of others besides its own faculty is not a university. Consequently we shall not argue the point at length. On the other hand, an institution officered by immature instructors is not a university, as we understand the term.

There are two very good reasons why the faculty of a technical school should engage in research. In the first place, a true teacher is also a student—he is curious about the unknown. There is that within his spirit which urges him to investigate. In the second place, the schools and their faculties must advance in order to hold their jobs. Abstruse science of yesterday is commonplace technology of today. So if there were not more new things constantly discovered, the engineering and scientific colleges would quickly become trade schools.

It seems agreed that investigation is necessary to the well-being of our schools. But what kind?

We believe that the true scientific researcher does not go to the XYZ bolt works and select his problem from its scrap pile, nor to the farmers of Jones' Corner and bring back a sample of bad vinegar. But with a background made up of thorough familiarity with the literature of his specialty, an acquaintance with the principal workers in the field and the useful applications which have so far been made, he selects one of the broader problems that remain to be solved and attacks the matter with a quite disinterested perspective. He throws all the resources he can bring to bear into the search, and in time, perhaps years, reaches a solution—or at any rate it becomes known that he is very well informed in that particular branch. Then with the advantage of this position, he is able to give the public the maximum amount of seasoned, correct advice with the least amount of distraction from his ordered routine. And that's the only kind of advice he will attempt to give. It is more than doubtful that this eminent and influential position could ever be reached by a university faculty that devoted itself to commercial research—which is time consuming, but rarely broad and never disinterested.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, Sept. 18, 1922.

CHEMICAL markets are, on the whole, featureless, prices remaining steady, although the outlook and industrial conditions continue to show improvement. Pitch and carbolic acid crystals are firmer, American demands being a favorable factor in the latter case. The trade in aniline dyestuffs and intermediates is improving. There is increased demand for sulphuric acid, about two-thirds of the available plants being in continuous operation. The recent reduction in railway freight rates is having a beneficial effect in enabling manufacturers to enlarge their areas of distribution, particularly of products for which transportation charges are a material factor.

REPARATION DYES TO BE DISTRIBUTED BY BRITISH DYESTUFFS CORPORATION

Perhaps the principal factor underlying this change in the Board of Trade's policy was the fear that the Central Importing Agency might ultimately compete with old-established traders. No attention is being paid to the critics who have made criticism their business at all costs without being in a position to propound any reasonable alternative. The corporation is to act substantially as agent of the government on a commission basis and the business is to be handled by a separate department not concerned with the disposal of the corporation's products. Prices are to be fixed by the government with an advisory committee on which the Color Users' Association is to have two representatives. The general impression is that the new arrangement will work very satisfactorily from the user's standpoint and the prospect of its benefiting producers is already reflected by an appreciation in the quotation for the corporation's shares. Sir William Alexander, the chairman, has emphatically contradicted the rumor that the color users are dissatisfied and his forthcoming visit to the United States should lead to a useful interchange and clarification of ideas on this very controversial industry.

INDUSTRIAL AND GENERAL DEVELOPMENTS

The British Cellulose Co.'s scheme for providing new capital is approaching fruition and prominent directors of the Société de Soie Artificielle de Tubize (Belgium) have joined the board of the company and of the "holding company" which is providing the new capital. Acetyl cellulose silk is now finding its way into the market and although, as is usual with a new product, its value is likely to be exaggerated, the fiber is being favorably considered as being a closer approach to natural silk in spite of difficulties in dyeing which are still in process of being surmounted. The prospectus of the "holding company" will be issued shortly and the £300,000 which is to be provided as first mortgage debenture stock is repayable in 1924 or by purchase in the market. There has been a very interesting exchange of letters between Sir Harry MacGowan, the managing director, and the Belgian silk works, from which it may be gathered that sales are increasing sufficiently rapidly to warrant an increase in the capacity of the plant from 1 to 3 tons per day and also for the installation at Tubize of a half-ton plant for manufacture of the new silk. This decision has been taken earlier than was originally provided for and indicates confidence on the part of the Belgian directors.

Owners of motor lorries and omnibuses are displaying interest in the use of "Discol" motor spirit, which is being marketed by the Distillers' Co., Ltd., and is mainly a mixture of alcohol (made from molasses) with benzol and other hydrocarbons. Considerable economies in fuel consumption have been recorded in this connection by the use of an economizer tank holding three quarters of an imperial gallon, which when filled with "Discol" fuel is stated to be of sufficient capacity for 150 miles run. The hot water from the radiator is circulated through a coil in this tank and by means of an adjustable air inlet a steady supply of gas of up to 30 per cent of the normal fuel requirements can be fed to the carburetor, variations in running being then taken up with petrol from the carburetor itself. The cost of the fuel is stated to be 1s. per gallon and increases of mileage of 75 per cent per gallon have been recorded, while the makers guarantee no pinking in the engine even at full load with ignition fully advanced.

SCIENTIFIC AND INDUSTRIAL RESEARCH COUNCIL ISSUES SEVENTH REPORT

Although much really useful work has been done in an unobtrusive way, a great deal of the work reported in this publication has not yet produced tangible results. As a contemporary aptly puts it, Faraday's simile "What is the use of a baby?" is still the best answer to scoffers at scientific research. Perhaps the most immediate benefit achieved lies in reduced consumption of fuel, increased output in gas works and the indirect fuel saving to shipowners from the steady work accomplished in the National Froude Tank. A saving of about 5 per cent was shown in many cement works with an increase of 10 per cent in output. Among the various state-aided research associations, those for the cotton and linen industry have done particularly useful work, while the food investigation board is able to record a success in the diagnosis of "brown-heart," a disease which affected apple shipments. Previously attributed to insects, it was found that the apples had been affected by self-evolved carbonic acid gas. Perhaps the most useful innovation is the establishment of co-ordinating research boards and committees to prevent overlapping and to facilitate investigations that are of common interest to several industries.

SUCCESS OF BRITISH ASSOCIATION MEETING

The meetings of the Chemical Section have this year had an exceptionally good lay press and as a result there has again been some criticism of the policy so frequently insisted upon by other learned societies of restricting publication prior to the appearance of contributions in the societies' own journals. None of the bodies criticised seems to possess sufficient courage to give the idea a trial and the critics are too apt to forget that the British Association is really an exception, inasmuch as it meets only once a year and possesses insufficient funds to publish the whole of the papers contributed to it. The symposiums on hydrogenation of oils and particularly that of the nitrogen industry were well attended. Dr. Harker's review of the nitrogen situation was really a masterly exposition, although the speaker's lips were unfortunately sealed in respect of some recent important developments. The published reports of the various papers presented are instructive reading from the national standpoint and tend to show that the German menace is still an important factor.

Detroit Meeting American Society for Steel Treating

Forty Per Cent of the Membership Present at the Best Convention the Society Has Ever Held —Papers on Carbonizing, Heating Practices, Tool Steel, Hardness and Metallurgical Education

EDITORIAL STAFF REPORT

STEEL TREATERS have done something which is perhaps unparalleled in the history of American technical societies—they have held a national convention at which 40 per cent of their entire membership nrolled as present. Being held in Detroit, several of he larger local chapters in the Middle West came in body, but in order to set that record a great many thers traveled from New England and the coast states. They were rewarded by the best meeting and exposion the American Society for Steel Treating has ever ad. Being but a young organization, the earlier conentions showed many marks of inexperience on the art of their managers. Much praise is therefore due the Detroit committees, under the general chairanship of W. P. Woodside, for their part of the work. They provided quite adequate meeting and exhibition acilities in the magnificent General Motors Office Buildng, gathered together a notable list of meritorious echnical papers, and provided a number of excursions nto manufacturing plants and social entertainments hich filled every minute. No doubt some of the sucessful results—particularly in the exposition of steel nd steel-treating equipment—were due to the coperation of the American Drop Forging Institute, hich held its annual convention in conjunction with he Steel Treaters as a sort of co-operative affair.

BIRTHPLACE OF BESSEMER STEEL IN U. S.

One feature of the non-technical activities is worthy f comment and emulation. It seems that the first essemer steel made in America on a commercial scale as blown in 1864 by William Kelly at the village of Vyandotte, on the river a few miles south of Detroit. he site of these works—now long since dismantled— the business center of the present community, but is ow marked by a bronze tablet erected by the Detroit nembers of the Society for Steel Treating.

Kelly, it may be recalled, was an ironmaster who ad discovered the pneumatic process many years before hen observing the action of the air blast on the metal n one of his forges, left unprotected by the usual charoal blanket. In fact, he had made knobbed iron with ttle or no charcoal for many years before he was able o interest anyone sufficiently to finance large experinents on what is now known as the bessemer process. plant was finally erected alongside the blast furnaces f the Wyandotte Iron Works, and operated with the sual vicissitudes of radically new processes for sevral months. A considerable tonnage of steel, however, as made, rolled and sold. During part of that time aptain Robert W. Hunt was in charge of the operaions, and fortunately this venerable engineer was able o be present at the dedication ceremonies and give ome reminiscences of those early times.

An echo of the vicious litigation which was fought ver the Kelly American patents, the bessemer British atent and the improvements made by Mushet was eard in the remarks made by William C. Kelly, the on of the discoverer of the pneumatic process. It seems that Kelly's achievements in the manufacture of iron without charcoal had become fairly well known, both here and abroad, through information spread by Kelly's Cincinnati house—jobbers and importers of iron and steel. During these times the forges were visited by two Englishmen of intelligence, who remained a few months, even assisting the owner in his experiments looking toward an improvement of the process or an adaptation to larger-scale operation, eventually leaving as suddenly as they appeared. According to the son, William C. Kelly, one of these visitors was identified by his father as Bessemer, when a photograph of the latter was brought over from England shortly after the introduction abroad of Bessemer's process in a commercial way. This incident, mentioned by William C. Kelly as never before having been made public, was told him by his mother before her death, several years ago.

Session on Carbonizing

CYANIDE HARDENING

Some experiments on case-hardening were reported by A. H. d'Arcambal, metallurgist for the Pratt & Whitney Co. He treated 1-in. rounds of S.A.E. 1015 steel in a bath composed of 76 per cent sodium cyanide, then removed the shell by 0.005-in. steps, analyzing each sample for carbon and nitrogen. A typical set of results are given below, after a heating for 45 minutes at 1,550 deg. F. and cooling in lime:

Sample	Carbon	Nitride Nitrogen
First 0.010 in.	0.44	0.353
Second 0.010 in.	0.22	0.036
Third 0.010 in.	0.18	0.017
Fourth 0.010 in.	0.14	0.009
¼ center drillings	0.14	0.006
Original stock	0.14	0.003

Carbon and nitrogen are both increased by temperature and time—e.g., 120 minutes at 1,550 deg. F. gives C 0.56 and N 0.451 in the outer 0.010-in. shell. Forty-five minutes at 1,450 deg. F. gives an outer case of only 0.30 C and 0.215 N. When hardened and fractured, the hard "case" measures about 0.010 in. deep for all heatings. Under the microscope, nitride needles are observed near the "breaking-off" point of the case.

IMPACT TESTS ON CARBONIZED SAMPLES

d'Arcambal also presented many data on the impact strength of several commercial steels after carbonizing 4 hours at 1,650 deg. F. in a mixture of ¼ sole leather, ¼ $BaCO_3$ and ½ hardwood charcoal. Subsequent heat-treatments were on the "high side" of S.A.E. recommendations, all samples being drawn to 350 deg. F. Some of the results are given in Table I (averages of 3 to 6 samples). Depth of case was measured under the microscope, and found to be 0.025 in. for the carbon steels and 0.03 in. for the alloy steels.

All pieces packed in sand and given the regular heat-treatment showed very much higher impact values than corresponding samples packed in the carbonizing mixture, a result to be expected. Heating for this long period in a neutral atmosphere will permit all soluble impurities to diffuse thoroughly; subsequent double

quenching will produce very fine grain. Izod bars so treated should show maximum toughness. Carbonizing, however, places a mass of very brittle martensite at the root of the notch, where the force of the impact is concentrated. Splitting of the specimen starts with a minimum of resistance, and results in correspondingly low values for the work of rupture. The double heat-treatments recommended by the S.A.E. give fine-grained fracture in case and core for all carbonizing steels, and the single quench refines the case, but leaves the core very coarse. The grain of an impure steel, such as bessemer screw stock, is not refined, however. All cases which had scleroscope over 90 were hard to a Nicholson flat temper-testing file; 3½ per cent Ni steels (S.A.E. 2315) gave scleroscope 87, and file-soft cases. After double quenching, all cases show a fairly fine martensitic structure, containing some globular cementite. The single quenching given preserves a trace of cementite network. Steel 6120 develops no network at any time. In general, this network is suppressed by quenching from the pot.

Izod values, in the single quenched condition, ranged the steels tested thus: 6120, 2315, 1015, 3115 and 1112. Oil-hardening gear steels range similarly—e.g., 6150, 2350, 3250 and 3150.

In view of the brittle material existing at the root of a notch, after the test-piece has been carbonized and hardened, it is doubtful if the impact specimens give results of much importance. Major Bellis noted that carbonized rifle receivers would withstand 150,000 lb. pressure under actual ballistic test, whereas the same part before carbonizing would fail at 85,000 lb. Notched test specimens, however, would invert the order.

Precautions in Carbonizing

H. B. Knowlton, of the Milwaukee Vocational School, recounted precautions which it is necessary to observe in commercial operations in order to insure uniform results.

First, it is necessary to have uniform carbonizing material. If this is homemade, or if a certain amount is being re-used, it is necessary that it be quite thoroughly mixed. Next, the temperatures must be under control. Time at heat is the most important thing to regulate, and in view of the variations in furnace firing, temperature of walls, loading of boxes, and so on, it is essential that the actual temperature at the center of the boxes be observed, either by a properly placed pyrometer or by frequent withdrawal of test pins Given these factors under control, the most fruitful source of trouble is leaky pots. Air or furnace gases entering them will burn the carbonizer, and the pieces near the leak or the top of the charge will actually be oxidized. Erratic results are also found on parts placed too near the surface of the pot, if the carbonizer shrinks and settles unduly.

Session on Tool Steel

Breakdown Tests

About twenty-five brands of commercial tool steel have been investigated by the breakdown test by H. J. French of the Bureau of Standards and Jerome Strauss of the Naval Gun Factory. Lathe tools (1x½ in.) of approved shape were given recommended or appropriate heat-treatments, and then tested dry to break down on a heavy duty motor-driven engine lathe, cutting a 15-in. forging of heat-treated 31 per cent Ni steel (Brinell 200). A feed of 0.045 in. and cut $\frac{3}{16}$ deep, was used. Under fast cutting, failure ordinarily occurred in less than 15 minutes. The amount of energy required to drive the lathe was not affected by the kind of steel in the tool.

Selection of the steels was made at random from about sixty-six lots of tool steel on hand. These had been analyzed and grouped into the following classes (analyses noted here being the average):

	C	Cr	W	V	Co
Low-tungsten, high-vanadium	0.65	3.7	13.0	1.5	
Medium-tungsten	0.66	4.0	15.0	1.5	
High-tungsten, low-vanadium	0.66	3.5	18.0	0.9	
Cobalt	0.69	3.7	16.4	1.2	3.3
Special (with molybdenum or uranium)					

Three tests were run, at various speeds, and the performance, noted as per cent of time of cutting of the best type, follows:

	Speed 67	Speed 61	Speed 60	Total
Low-tungsten steel	100	94	100	294
Cobalt steels	68	100	97	265
High-tungsten steels	56	55	64	175
Medium-tungsten steels	54	56	62	172

There seems to the authors to be such a great variation in the results, both for individual tools in the same test and for the class averages in tests which have their only difference in a minor change in cutting speed, that breakdown tests should not be relied upon to govern large purchases of tool steel in a competitive market, except when the tools are for very heavy roughing work, as in the test itself. There seems to be no doubt, however, the low-tungsten steels or cobalt steels are definitely better for this duty than the high-tungsten varieties.

Uniformity of the tests became better as the severity was reduced, and was very good when failure occurred at about 20 minutes, the time recommended years ago by Frederick W. Taylor. Mr. Spaulding recommended Taylor's method rather than the severe breakdown tests, because he had found that the former gave results which could be duplicated consistently to within 5 per cent, regardless of the kind of cutter or tool tested J. H. Parker, on the other hand, told of an extended breakdown test which selected steel X as being best and Y as second choice. Twelve sizes of each steel were then purchased, six tools were made by each size and put into regular production, working on appropriate

machines and various alloys. Ten grinds were given each tool. In every shop test, X (a low-tungsten, low-vanadium steel) was first, and Y (a high-tungsten, low-vanadium steel) was second.

Proper Microstructure for Best Machining

J. V. Emmons, of the Cleveland Twist Drill Co., presented an account of that company's extended studies on the influence of the microstructure of high-carbon tool steel upon the ease and excellence of the machining operations necessary to form it into a cutting tool. Such steels as received by them, having been given an anneal at the mill, would always show more or less massive cementite (the remains of the original network) more or less sorbite or pearlite, or pearlite in various stages of decomposition to ferrite plus spheroidized cementite. The variations cause troubles of such moment to them that they anneal all such steel received to a definite microstructure found most suitable to their shop conditions. If a variety of machining operations —such as turning, milling, fluting and tapping—have to be done on the same piece, a compromise structure is chosen. In general it will usually be one containing but few traces of the original massive cementite network, and perhaps only 25 per cent of the area covered by lamellar pearlite, the rest being spheroidized. In general, these slight changes in structure have far less influence on the final hardness and toughness of the steel, if they are given a heat-treatment in keeping with their constitution. For instance, if coalescence of the cementite is into unduly large particles, the tool must soak for a longer time at the hardening heat to get these carbides uniformly diffused in the austenite.

Several speakers emphasized that Mr. Emmons' paper was one which should be used as an indication of the correct principles of operation rather than a detailed guide. There seems to be a very powerful "shop factor" operating in such problems. For instance, several manufacturers of taps have shop methods and machines which are practically identical, and purchase steel of the same chemical composition. Yet one will specify a maximum Brinell hardness of 160, and another a minimum of 200. Each believes he is getting the best material for quantity production. Similarly manufacturers of ball bearings use the same shop methods and the same kinds of steels. Yet Plant A prefers 160 Brinell, B specifies 160 to 180, and Plant C demands 180 to 200.

Hollow Drill Steel

A brief account of the terrific duty which is imposed on hollow steel for rock drills was described by N. B. Hofman, of the Colonial Tool Steel Co. Until about 2 years ago nearly all of this steel used was a plain carbon steel. Since that time several attempts have been made to market alloy steels, but they have not been entirely satisfactory, owing to the fact that the forging and hardening of the steels is invariably done in the crudest blacksmithing manner by men who do not understand the idiosyncrasies of modern alloys. However, a steel containing 0.75 to 0.85 C, 0.25 to 0.35 Mn, 0.12 to 0.16 Si and 0.2 V has given very excellent results. It is hardened and tempered like the more usual carbon steel, and has given from two to three times the life in endurance tests and actual service. One difficulty still to be overcome is in the condition of the metal surrounding the longitudinal hole. By common methods of manufacture it is decarbonized and too often full of minute cracks or folds from which detailed fractures—the so-called "fatigue failures"—commence and spread rapidly.

Session on Heating Practices

Scale Formation Upon Heating Steel

G. C. McCormick, of the Crompton & Knowles Loom Works, Worcester, pointed out that the terms "neutral atmosphere" and "reducing atmosphere" as used in shop parlance are misnomers. His experiments show that it is impossible to operate a semi-muffle furnace without badly oxidizing steel left in it for an hour at temperatures greater than 1,200 deg. F.

Using a tube furnace, with an atmosphere of still air, he plotted the losses by scaling[1] after an hour's exposure at various temperatures. The curve resembled a parabola—the loss was very low at 1,200 deg. F., but increased at an accelerating rate, and at 1,600 deg. was excessive—0.50 gram per sq.in. of surface. In all the experiments, low-carbon steel scaled more readily than high-carbon, probably because the latter had to be decarbonized as well as oxidized.

Shopmen call a "neutral" atmosphere one where the fuel is fed into the combustion chamber with just sufficient air to burn it. The furnace then contains an atmosphere made up of the products of combustion: little or no oxygen but much CO_2 and H_2O, both of which, as a matter of fact, oxidize steel badly at high temperatures. It was shown that the scaling loss in a furnace operating with such a "neutral" atmosphere was about as great as in still air.

Again, the term "reducing" atmosphere refers to one where an insufficient amount of air is supplied the burner; therefore the furnace atmosphere contains more or less CO, H_2 or unburned hydrocarbons. It is characterized by a "hazy" heat and flames burning around the door and exhausts. Mr. McCormick experimented in a furnace which was operating on the maximum surplus of gas possible to give it. The atmosphere analyzed 11 per cent CO_2, 0.8 per cent CO and no oxygen. Nevertheless scaling continued at about half the rate in still air.

It is recognized, of course, that for brief stays at temperatures even much above 1,600 deg. F. oxidation may be materially reduced by operating with a large excess of fuel. Yet it appears impracticable to produce an atmosphere in a commercial semi-muffle furnace which will not scale badly after several minutes at temperatures above 1,200 deg. F. In other words, "a high-temperature furnace always scales." Consequently the ordinary terms "neutral" and "reducing"—when referring to atmospheres in such furnaces heating steel —should be abandoned.

Electric Furnaces

C. L. Ipsen presented a brief paper describing some electric furnaces which have done very good service in heat-treating. The heating elements consist of loops of bare nichrome ribbon, hung on refractory lugs built into the furnace lining. These loops may cover the side walls, roof and even be placed under the floor, which latter is usually constructed of a good conductor of heat, like special alloys or carborundum brick. Turret furnaces with rotary hearths are becoming very popular for continuous production. One such has now been in operation 8 hours daily for 3 years without any expense for renewals. Current is switched on auto-

[1]Scale was removed by dipping the steel into cyanide for 10 minutes at 1,450 deg. F., quenching in water, and cleaning in soda.

matically at 4 a.m., the furnace is up to heat when work starts in the morning, and is automatically controlled during the day. Furthermore, such furnaces avoid the smoke, heat and noise of a fuel-fired furnace and may be installed in their proper place in the production stream without becoming a nuisance. Furthermore, annealing may be done in automatic electric ovens at night, requiring practically no attention and taking advantage of low rates for off-peak loads.

Discussion on Hardness

An extended discussion on hardness testing was held under the chairmanship of Major A. E. Bellis, in which a large number of members participated. Dr. H. P. Hollnagel, of the Lynn plant, General Electric Co., laid the matter open in a paper describing the various popular methods of measuring "hardness" and the inherent difficulties in standardizing and correlating them.

"Scratch hardness" is the oldest method, and perhaps the most used. A physicist performs the test by drawing a minute jeweled point across a smooth surface, and examines the width and depth of the microscopic furrow cut across the individual crystals of the piece. Ordinarily, an engineer is more interested in the properties of an aggregate of crystals, rather than of the individual crystal—he takes a set of standard files, and judges which will just scratch the piece. In this way he gets a relative value. File testing, however, would probably be most difficult to standardize—the files themselves would have to be quite uniform and never used after slightly dulled; furthermore, the speed and cutting pressure introduce a very large personal factor. As an illustration: If conditions are right, diamond will cut diamond, and chalk will polish quartz.

"Wear hardness" has been proposed as a term devoting the time required to wear 0.001 in. from a pin under a fixed load. In such a test the original surface becomes quickly polished (covered with an amorphous film) and therefore the specimen hardens as the test proceeds.

"Penetration hardness" denotes the usual method employed by metallurgists, wherein they press a ball or point into a surface and measure the indentation. To perform the test the material must be overstrained, thus automatically hardening the deformed material. In manganese steel this characteristic is so aggravated that figures for penetration hardness do not mean anything. In other metals, the method is extremely useful, despite the limitation that its results are greatly influenced by the properties of the material in its deformed state—even when the test is so superficial as barely to penetrate the surface.

Deformation under impact has been utilized in many commercial hardness testers. Some of them are of the semi-resilient type, where the indications are estimated by the rebound of the testing implement. This method is thought by Dr. Hollnagel to be especially defective, since the rebound is a function of the duration of impact, which in turn varies with the manner and speed by which stress waves travel through the body which is struck. Of all kinds of hardness, that kind which presents resistance to a rapid penetration—like projectile and armor plate—is the most difficult to control or reproduce.

Even when the ideal test is established many of the present hardness tests, and more to be devised, will always be useful for "inspection" purposes. Of course, they will give only relative figures, and in some cases will only be able to pick out defectives from parts supposedly all the same. Their use will always involve a large personal factor and considerable common sense—nevertheless, they are performing a very useful rôle in technical control of shop practices.

It would be desirable, as Sam Tour pointed out, if the term hardness could be defined, or some new one invented to which could be ascribed some definite physical property, thus having a connotation free of the many shades of meaning associated with our present word. Unfortunately, all of our present tests are called "hardness" tests, even though they obviously measure different combinations of qualities, so different that correlation is quite impossible.

Metallurgical Education

A symposium on metallurgical education under the chairmanship of Prof. S. L. Goodale, of the University of Pittsburgh, brought out many suggestions from practicing engineers on "What to Teach" and in return educators told how the colleges were meeting these new demands. Both parties were agreed that the basis of a sound metallurgical education was a solid foundation in the great art of language and the fundamental sciences—mathematics, chemistry and physics. University professors were apparently unanimous in the belief that the technical student should also give much more attention to the so-called "humanities"—ancient languages, literature, history and fine arts—and the newer studies, economics and psychology. In fact, the demands upon the modern engineer, first as a citizen, and then as a specialist, appear to require such thorough preparation that there is a distinct trend toward the 5-year course. In this additional year of college life the student could really specialize in his chosen field, already having been fitted by a much more general education to enter any one of several engineering specialties. Undoubtedly such a 5-year course, properly taught, would make better engineers and better citizens, but it was recognized that such an innovation would have to be approached with care, in view of the present unpopularity of a lengthy college course. On the other hand, it was pointed out that nearly if not quite all university curricula in metallurgy were offshoots of schools of mines or of chemical engineering and contain many studies which have only a remote bearing on metals and their alloys. If these excrescences could be removed—or in other words, if a real metallurgical curriculum could be established—there would then be available no small amount of time for "humanities" without extending beyond the conventional 4 years' time.

There is of course one very important kind of metallurgical education which lies beyond the university. It consists of teaching artisans—machinists, toolmakers, blacksmiths, forgemen and heat-treaters—as well as foremen and executives—something of the great advances which are being made in the art and science of alloys. Many of these men can never be reached, because of their own mental stagnation. On the other hand, the American Society for Steel Treating, through its frequent local meetings, the technical press and the trade and continuation schools, is doing a great deal for the younger and more ambitious men engaged in manufacturing metallic goods. Much leavening of this whole mass is being done by the graduate metallurgist himself. When he enters a plant he finds his activities touch many of the operating, executive and selling departments, and, if he is the right sort, he preaches the gospel of "quality" in metal in season and out.

Handling the Finished Products of Industry—V

Handling Bricks From Kilns for Storage and Shipment Is a Problem Easy to Solve—Why Modern Methods Have Not Been Generally Adopted in This Industry—Suggested Solution Based on Experience of American Enameled Brick & Tile Co.

By Graham L. Montgomery

THE OPERATIONS in the average brickyard are particularly adapted to the successful application of mechanical handling equipment. The basic raw materials are few in number and are received in relatively great bulk. The additional materials used are of such small bulk that the means used for handling them is unimportant. In the treatment of the material for manufacturing the brick, from the first operation which the raw material undergoes to the point where the burned brick is removed from the kiln, we have a manufacturing process which is ideal for the application of straight-line flow and automatic handling methods. After the bricks leave the kiln, whatever the design of the kilns may be, they are products of a form which permits the simplest and most economical type of handling.

The conveyor engineer or the experienced conveyor salesman can hope for no easier job than that of laying out a handling system for handling finished brick. The product is uniform in shape and weight. The sources of origin—the kilns—will be approximately all in the same location. Any intermediate operations which may happen to the brick, such as sorting and storage, will happen to all of the products, and may easily be arranged to occur in a straight line between the kilns and the point of shipment. Since the product is entirely uniform, the method used in shipping will be exactly the same, and therefore presents a splendid field for the application of mechanical carloading equipment.

Status of Handling for Finished Bricks

In spite of these considerations, there is scarcely a brick plant in the country which is taking full advantage of the saving to be made through the use of this mechanical equipment. Some plants have made a beginning and have applied conveyors here or there; and the plants that have done this have found they derive a distinct advantage from the use of these machines. A large majority of plants, however, have failed to take any advantage whatever of equipment of this type for handling the product at any point beyond the kilns.

Attitude of Some Ceramic Engineers

Perhaps the reason for their attitude is explained by the attitude taken by some of the leading ceramic engineers of the country. As an example of the attitude which these engineers take I quote from the work of Ellis Lovejoy on "Economy in Brickyard Construction and Operation." Mr. Lovejoy in his chapter entitled "Drawing and Loading" writes as follows: "We wish to express our respect for the wheelbarrow. We have little use for a wheelbarrow in handling clay, but in handling the burned product, the wheelbarrow makes a brave showing in competition with any other method."

When engineers who are presumably leaders in their field write in this manner, it seems hopeless to look for an appreciation of modern equipment on the part of those whom we may assume to be under their guidance. The situation is not, however, as bad as this might lead one to believe. There is at the present time a distinct shortage of cheap, unskilled labor. For this reason many of the brickyards, in order to produce and ship any product whatever, are under the necessity of adapting some mechanical means of handling. The wheelbarrow, which Mr. Lovejoy admires so much, was undoubtedly an economical appliance in the days of free immigration from Europe. Under present conditions the unskilled laborer, when it is possible to hire one, wants almost as much for his day's work as the most skilled man in the plant. For this reason operators of brickyards are thoroughly aware of the fact that they must revamp their methods in such a way as to abolish the horde of wheelbarrow pushers which at present characterize this industry.

Handling at American Enameled Brick & Tile Co.

As an example of what has already been done in handling finished brick, the plant of the American Enameled Brick & Tile Co., at South River, N. J., is suggestive. The methods already established and working at this plant indicate a simple extension to complete mechanical handling. This extension could be made without any change whatever in the plant layout, and would necessitate only a slight change in the operating methods now in vogue.

The products of the American Enameled Brick & Tile Co. consist of brick and tile having one or more white porcelain enameled faces—such material as is commonly used for engine rooms, basements and swimming pools. Bricks of this type are among the most difficult to handle. Any unduly rough treatment is sure to damage the enameled face. It is also necessary to subject these bricks, after they leave the kiln, to a most searching inspection. Only those bricks which are absolutely without flaw can be sold as first-grade enameled bricks. Bricks having cracked enamel or other defects must be separated out, classified and sold as seconds or thirds.

How Handling Equipment Was First Used

The management of this company had considered the installation of conveyors for many years, but with the consideration of their particular difficulties in view, they did not feel that this equipment could be installed and used without resulting in more damaged product. During the war this plant went extensively into the manufacture of firebrick for the government. This required no change-over in the arrangement of the plant, as the base material from which the enameled brick is made is the same as that from which firebrick is manufactured.

Due, however, to the fact that they had no problem of enameled faces to deal with, it was thought that greater efficiency could be realized in the face of the labor shortage by installing conveying equipment for unloading the kilns and for taking the brick from storage and other points to the cars in which they were shipped.

*Previous articles in this series have appeared in *Chem. & Met. Eng.* as follows: Article I, vol. 26, No. 18, p. 823, May 3, 1922; Article II, vol. 26, No. 19, p. 885, May 10, 1922; Article III, vol. 26, No. 24, p. 1,114, June 14, 1922; Article IV, vol. 27, No. 5, p. 199, Aug. 2, 1922.

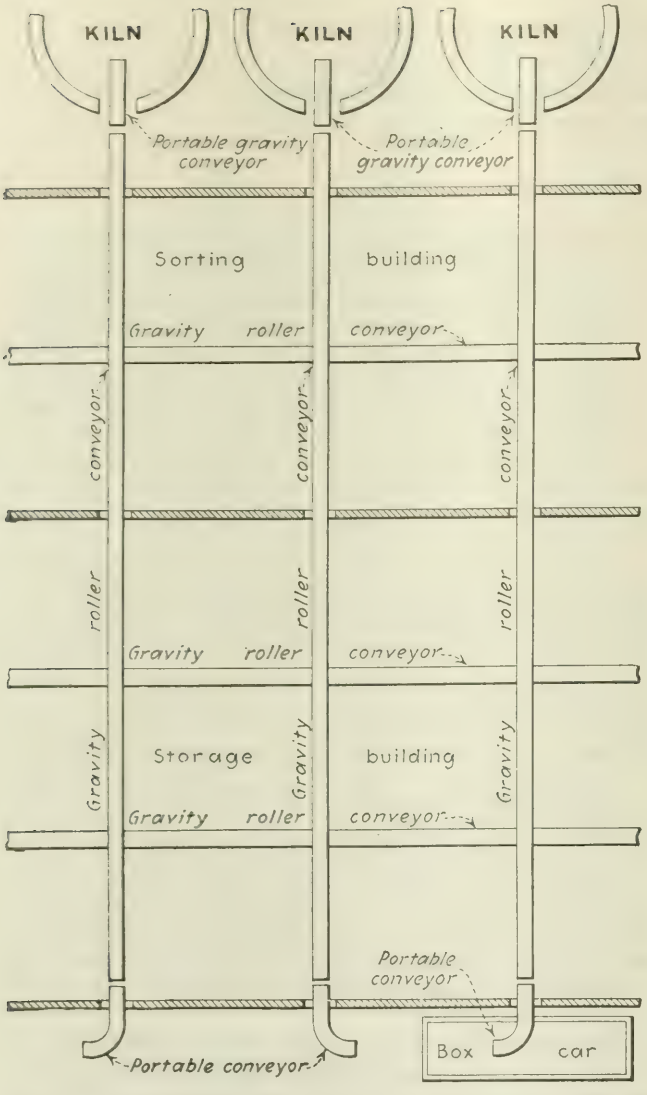

FIG. 1—DIAGRAMMATIC LAYOUT OF HANDLING SYSTEM FOR BRICK FROM KILNS TO STORAGE AND SHIPPING

Consequently, gravity conveyors were installed for this purpose.

Layout of This Handling Equipment

Reference to Fig. 1 gives a diagrammatic idea of the layout of the kilns, the storage space and the location of the shipping track. This sketch is not an exact reproduction of the plant, but does give the relative position of these various elements. The space on the sketch which is marked "sorting building" is used in the production of enameled brick for sorting the brick into the various grades in which it is sold. After the sorting is accomplished, the bricks are taken into the storage building and piled to await shipment. When shipment occurs, they can easily be taken through the doors of the storage building directly into the cars in which they are to be shipped.

This handling was formerly accomplished in two ways: Between the rows of kilns and extending into the sorting building are industrial railway tracks; at right angles to these tracks extending between the kilns in the other direction and extending up and down the floor of the sorting building are other industrial railway tracks. By means of a transfer car, then, the bricks could be unloaded from any kiln and taken to any position in the sorting building where they were to be sorted. After the sorting they were loaded on handbarrows and wheeled to the required position in the storage building or directly into the car if shipment was to occur immediately.

The industrial railway, such as described above, is a common type of handling equipment used in the few plants which have installed any handling equipment at all at this point. This apparatus is quite flexible enough for the service and is fairly cheap to operate. But its operation either requires power in the form of a storage battery locomotive or requires that the cars be pushed by one, two or three men, depending on their weight. Of course, these men may not all be necessary to push the car along a straight run of track, but at the transfer point their services cannot be dispensed with. It is plainly good business to dispense with this extra labor if possible.

Handling Firebrick

In handling the firebrick, it is evident that the brick can be taken directly from the kilns to storage or to the cars by gravity conveyors. The kiln floor is some distance above the floor of the manufacturing building. This is because of the fireboxes and flues of the kiln, which are on the floor level, the kiln floor being above these. This permitted sufficient slope to be given to a gravity conveyor to run the brick directly across the sorting and storage buildings into the cars.

This routine worked very well with the firebrick where there was no necessity of sorting prior to shipment and where the product was of such a nature that it was not necessary to take particular care in handling it. In practically every plant manufacturing common building brick or firebrick, this system can be applied, if the plant layout is of the straight-line type. Where the necessary drop in the gravity conveyor is not available, it is a simple matter to depress the loading track. The expense entailed in such depression would easily be covered by the wages of the wheelbarrow pushers who would be dispensed with by this course of action.

Special Care Needed to Handle Enameled Brick

When it comes, however, to the handling of products such as face brick and enameled brick, where the purchaser desires a definite standard of perfection, the brickyard is faced with a more difficult problem. There seems to be a general doubt among superintendents and managers of plants of this type as to the possibility of handling their product on conveyors of any type without damaging it in some way.

At the present time, at the American Enameled Brick & Tile Co., the enameled brick is handled in two ways. The usual way is approximately as follows: A short run of portable gravity conveyor is placed to extend from within the kiln to a point adjacent to the nearest industrial railway track. The men in the kiln place the bricks on this conveyor, and the men at the other end remove them and place them on a rack-car on the industrial railway. This operation is completed without any damage whatever to the brick. In fact, there is much less damage than there would be if the brick were loaded directly from the kiln to the industrial railway car by hand, as several passings of the brick from hand to hand are eliminated.

Sorting Face Brick

After the industrial railway car is loaded, it is pushed by hand along the track and taken by means of the

transfer car to the desired position at a sorting table in the sorting building. The bricks are here sorted and piled according to the various gradings in vogue. They are taken from this sorting building to the storage building, or in some cases directly into the cars, on hand-loaded, man-pushed wheelbarrows. From the storage building, they are more often loaded into the cars by a second portable gravity conveyor. In this case, the men pick up the brick from the pile in the storage building, several at a time, place them on one of the papers which are used to separate them in the box-car and permit this package to run down the gravity conveyor into the car. This work also is accomplished without any damage to the bricks—that is, provided the men who are handling them take sufficient care in placing them on the conveyor and removing them from it. By sufficient care it is not meant to imply that such extreme care is necessary as to slow up the operation. It is only meant that the handlers shall not carelessly knock the faces of the brick against one another, or against the framework of the conveyor.

Full Conveyor Handling for Finished Brick

At other times when conditions are right in the plant, a full run of conveyor is placed directly from the kiln into the car. In this way, by having the bricks pass slowly through the sorting building, it is possible to select from the conveyor all those grades which are not to be shipped in that particular car and to permit only the desired grade to continue on through the storage into the car should it be desired to sort in this way. The flexibility of application of this system is evident, as it is possible at any time to stop the bricks at the sorting place, at the car, or any other desired point in the plant merely by the extension of the portable gravity and by the introduction of a few small power boosters.

Referring again to Fig. 1, we see there the possible ideal extension of this gravity handling system by the application of fixed conveyors. The three runs of gravity conveyor extending across the page and the three runs extending perpendicular to them could well be permanently installed. By the application of switches at the intersection of these conveyors and by using portable conveyors to connect the permanent conveyor to any kiln, to load or unload bricks to or from the permanent conveyors at any portion of the sorting or storage buildings, and to take the brick from the end of the permanent conveyors into the cars, a system would be established which would eliminate all possible rehandling of the brick from the time it left the kiln until the time it left the plant.

Operation of Full Conveying System

To operate such a system, it would be necessary to develop a certain routine and technique so that the brick would move regularly and without damage. But no matter what the handling system used may be, there is a routine and a technique of some kind which must be developed in the handling. It is evident in any case that the fewer the number of rehandlings which the brick undergoes the less chance it has of being damaged. Experience proves that brick cannot be damaged while it is passing along the conveyor, if it is placed on the conveyor in a correct manner. The majority of the damage seems to have occurred in the past when the brick was passed from hand to hand in unloading the kiln, when the brick was placed on the barrows in the sorting or storage building and when the brick was again passed from hand to hand in the car.

With this means of mechanical handling as used at present in the plant described, there has been effected an increase in the number of bricks which a given number of men could handle in a given time of about 20 per cent. If such an increase can be effected by a partial application of the system, the savings effected from a full and judicious use of this type of conveyor should be even greater and more worth while.

The writer wishes to acknowledge the courtesy of the American Enameled Brick & Tile Co. in making available the data on which this paper is based.

Production of Clay for Sale Decreases in 1921

The output of clay mined and sold as clay in the United States in 1921 was 1,716,746 tons, valued at $6,025,300, or $3.51 per ton, according to the United States Geological Survey. This was a decrease of 45 per cent in quantity and 48 per cent in value as compared with 1920. These figures represent only clay sold as clay by the original producers; they do not include the much greater quantities of clay burned into clay products by the producers themselves.

The production of kaolin, the clay that is used in making high-grade pottery and porcelain as well as paper and other products, was 162,726 tons, valued at $1,579,-163, a decrease of 39 per cent and 45 per cent, respectively, as compared with 1920. The clay of largest production and value is fireclay. The sales of fireclay in 1921 amounted to 1,195,861 tons, valued at $3,560,373, a decrease of 49 and 52 per cent, respectively, as compared with 1920. The output of every kind of clay as classified by the Geological Survey in its statistical report decreased in quantity and value in 1921 as compared with 1920.

The imports and exports of clay also decreased in 1921 as compared with 1920.

Factors Affecting Yield of Carbon Black

Factors of utmost importance in the efficient recovery of carbon black from natural gas are the design of a plant, the kind of lava tip used, the distance from the depositing surface to the top of the lava tip, the arrangement for admitting air and the rate of movement of the collecting surface. Provision should be made in construction for changing the height of burners, as different gases require different distances below the depositing surface. In West Virginia the lava tips are about 3 in. below the channels, but in Louisiana this distance is too great. By changing the position of the lava tips, one company in Louisiana increased its production of carbon black 20 per cent. If the tips are placed too near the collector, the flame tends to pass around the surface and loss of carbon black in flue gases increases. The rate of actuation of the depositing surface affects the quality of the carbon black manufactured more than it affects the quantity recovered. This factor, therefore, is determined by experiment; it is one of the flexible features, whereby various grades of black may be made by using the same method. The devices for admitting air are controlled by using as an index the color of the smoke issuing from the buildings, the superintendent having in mind the quality of black to be made and compensating losses in flue gas according to the quantity of black recovered.—*From Bulletin 192 of the Bureau of Mines.*

Sulphuric Acid Recovery In Oil Refineries

By Lewis B. Skinner
Consulting Chemical and Metallurgical Engineer

IN THE early American practice recovered sulphuric acid was evaporated in lead pans to a strength approximating 60 deg. Bé. and then brought to 66 deg. Bé. in a number of glass retorts or stills, each having an average capacity of about 40 gal. The lead pans, in series, were fired by a number of oil burners. The glass retorts were fired separately and individually, and the waste heat from them was passed generally to the pan flues.

Each retort was bedded in sand, so as to furnish a uniformly distributed support for such fragile material, since, if improperly carried, the swirling and bumping of the acid would be likely to break the glass. The upper part of the still projected above the arch of the firebox to such an extent that the top level of the acid was above the brickwork after the original charge had been reduced in bulk by the concentration. Each retort was charged with 60 deg. Bé. acid from the pans. After the acid had been evaporated down to 66 deg. Bé., it was siphoned off and the retort recharged. All these operations required careful and experienced manipulation.

Dilute sulphuric acid may be evaporated by heat up to a certain point without loss, unless substances are present which cause decomposition. The dilute evaporating mixture does not reach a boiling point approaching the melting point of lead or possess chemical activity of such a pronounced nature as to rapidly destroy the metal until a strength above 60 deg. Bé. is attained. Lead pans may therefore be used in concentrating part of the way, and condensation of the distillate produced is not required. The evaporation above 60 deg. Bé. is attended by a loss of acid as well as water, so that it is necessary to collect and recover the fume or distillate. Each still was provided with a glass connector set in a hole at the top, for the purpose of delivering the vapors to one of a number of openings in a lead condenser pipe, ordinarily submerged in water in a lead-lined, wooden box. Cooling water was fed at the end of the condenser system farthest from the stills and removed at the hot end.

Platinum Stills Given a Trial

In the early days, the oil refineries usually shipped their separated acid to the chemical manufacturers for concentration but, in spite of the careful attention given, it was found that the intermittent style of operation, the breakage of glassware, the high cost and uncertainty of the material and the man-handling required made the concentration too costly. Platinum stills having lead covers and arranged in series to run continuously were tried, but it was felt that the high cost for interest on investment and for amortization, along with lesser evils, made such equipment undesirable, so cast-iron stills were introduced.

Cast-Iron Still With Lead Cover

Eventually, all the chemical plants abandoned the glass retorts in favor of cast-iron stills. These were provided with lead covers, somewhat pyramidal in shape, over which cooling water was cascaded. Later, the oil refineries adopted this style of equipment themselves, feeling that they should eliminate the expense of handling and freighting the water in the weak acid, and also avoid the cost due to the corrosion of ordinary metals when shipping such material in bulk.

The design handed over by the chemical manufacturers has been largely adhered to in later built refineries until quite recently. Now, however, there seems to be a desire to get rid of a method which is particularly obnoxious when large tonnages are to be handled. Such layouts are undesirable because the stills are small, because the water-cooled lead covers abstract heat from the acid being concentrated below, because the leadwork requires almost constant attention from high-priced mechanics, because neither the latent nor the sensible heat transmitted to the distillate vapors is conserved, because of the slopping about and the cost of the water used for cooling and because of the high consumption of fuel oil.

Having designed and built a number of pan-and-still sets, the author does not recommend the complete abandonment of this style of apparatus. There are situations where the desirability of its use is indicated. With a relatively low first cost in its favor, the arrangement, properly modified, may be employed to advantage, either when small quantities of acid per day are to be concentrated or when tenure of life for the plant is not reasonably assured, or when sludge acid is not produced regularly or at a reasonably uniform rate. A low-cost standby for peak tonnages should be available in addition to the regularly run equipment.

Improvements in Cast-Iron Still and Accessories

The modifications or improvements consist in the use of large stills, cast-iron covers, a small, packed, heat-exchange tower, to which the fumes from the stills are taken by a slight suction and condensed by contact with the cold acid being fed to the system, and a rigid form of construction which does not permit the bulging ordinarily produced by acid stills. The small tower cuts down the quantity of fuel oil required when water-cooled condensers are used, because it provides for the efficient utilization of approximately one-half of the heat delivered to the stills, which heretofore has been wasted in the vapors. It does away with that part of the pan area formerly needed to bring the feed acid from its cold state to the temperature of actual evaporation. It renders unnecessary a cumbersome condensing system with its attendant repairs and the demand for a supply of condenser water, and it avoids the nuisance arising from the leakage of fume from the numerous joints of a condenser train.

Since the strength of the pan acid delivered to the stills is usually 60 deg. Bé., and this, when concentrated to 66 deg. Bé., produces a given amount of fume and requires a definite amount of heating surface, the size of the tower and stills can be fixed, but the area of the pans must be varied to suit the strength of the weak acid to be fed and the amount of organic matter to be contended with.

To obtain 20 to 25 tons of 66 deg. Bé. product from 35 deg. Bé. feed acid, an oil-fired plant should have eight lead pans in series, of a combined area of about 1,200 sq.ft.; two cast-iron stills of about 50 sq.ft. and a condenser tower about 5 ft. square, lead to lead, and 18 ft. high.

Since pan-and-still layouts should evaporate the water from the surface of a weak acid instead of distilling it through a scum, the mixture of oil and carbon that

orms on the surface of the liquid should be skimmed egularly throughout a shift, the routine to be adopted epending upon the kind of material being run. To vaporate below the boiling point, advantage should e taken of the physical law that liquids in contact ith foreign gases are affected in a general way as hough in a vacuum. A stream of gas passed through liquid produces the effect, at the surface of each ubble, of a tiny vacuum pump. A rapidly changing tmosphere, acting upon the film at the surface of a iquid body, has the same effect. Therefore, in order o get the benefit of the contact of the water in the veak acid and the atmosphere, the viscous, semi-solid, loating organic matter should not be allowed to inter- ose itself any longer than necessary. Provision should e made for ready access to every one of the lead pans.

The organic matter present reacts with the sulphuric cid and decomposes it. The effervescence of the fixed ases formed produces a mist, so that working over he pans in the atmosphere created is certain to be ndesirable even under the best of conditions, and articularly so when the plant is a large one. To vercome this and the other objectionable features of igh repair cost of burnt out pans, time lost in such epairs and in replacing stills, high fuel consumption nd other annoyances, the author designed tower con- entrators, arranged in a special manner.

The Skinner Tower Concentrator

For sludge acid, a plant consists of four towers; one or evaporating weak acid without condensation of the apors, since they do not contain sulphuric acid; one or bringing the partially concentrated acid to 66 deg. Bé., wherein fume is produced; and two in series con- ected to the strong concentrator, for condensing this ume.

The strength to which the feed acid is brought in the vaporating tower depends upon the kind of oil-treat- ng that has been done. The temperature applied in he tower and the elimination of a part of the water auses, in many cases, a separation of oily matter without a noticeable decomposition of the acid. To furnish some idea as to the part of the work done in his preliminary treatment, it appears that a concen- ration to 50 deg. Bé., approximately, works well. How- ever, the great variety of products treated and the hanges in oil-refinery practice do not permit of a defi- nite statement. This is not a serious matter in con- sidering the plant engineering and may be settled by bservation of plant-running, in co-operation with laboratory research.

Heat is applied by direct contact of products of combustion with acid, the gases being furnished at a high temperature from a firebox attached to the tower at its base. Draft is induced by an exhauster requiring very little power, since the tower itself has a pronounced chimney effect. Carbon should not be introduced into the acid by the fire gases. In using fuel oil, this is guarded against by having two arches in the firebox, which zigzag the gases before entry into the tower. When coal is used, the result is attained by a specially designed underfeed stoker.

The evaporating-tower product is led to coolers and separating tanks where the oily matter is continuously skimmed from the acid to be further concentrated.

The strong-acid concentrating tower is built more substantially than the weak-acid tower, inasmuch as it is subjected to much greater punishment. The condenser towers are arranged in a rather simple manner, since they are not subjected to high temperatures and pronounced corrosion.

For work of this character, it has not been the author's experience that capital expenditure is lessened as a result of constructing towers of special acid-resisting brick or other shapes. The laying of such is very expensive, owing to the extreme care required from especially trained bricklayers in fitting tight and close joints, in selecting only bricks which are true to dimensions, and in chipping interminably to make tight fits. In the case of the concentrators, square steel frames are used for supporting lead sheets, the latter being lined with ordinary vitrified brick which are cheap and may be put in place rapidly in acid-resisting cement, by ordinary workmen. The condensers are not lined; it is not necessary and cuts down capacity. The wall lining is of sufficient thickness at the various heights to prevent the high inside temperature from reaching the lead sheets outside. Vitrified bricks, spaced sufficiently far apart to minimize the tendency of the solids introduced with the acid to "bridge across," are used for packing.

Tower Packing

The use of broken material of various sizes and shapes is likely to take up solids from the acid and obstruct the draft. Brick packing, spaced regularly, reduces this possibility and therefore provides for higher average daily tonnages. When broken material is used in towers, it is assumed generally that the voids produced represent 50 per cent of the volume of the solids. This may be so at the outset, but dirt settles out readily on the horizontal or nearly horizontal surfaces, eventually closing open passages, with the result that only a few irregular vertical channels are left to do the work. The void area is required to take care of the extremely large volume of gas which must be passed compared to the small amount of liquid so that, even though constricted, the liquid may flow freely enough, while the gas cannot. Washing a tower packed with broken material does not prove very efficacious, because the solids, being supported as indicated, are not readily dislodged, even though a flood is passed for some time.

Relatively massive arches, at a considerable height from the tower base, are used in the concentrators for supporting a short column of packing. Such an arrangement permits the anhydrous ferric sulphate mud to precipitate from the acid when it is raining down, instead of in the packing where it would tend to bridge across the voids and to obstruct the draft. Such a condition develops when the arches are placed down near the tower base, as is generally done. Then too, were single bricks exposed to the destructive influence of strong, hot acid and fire gases at an efficient firebox temperature, as would be the case were the packing supported on arches near the bottom of the tower, they would be cracked and spalled, with the result that the packing would become disarranged and the tower obstructed in a manner not to be overcome by washing. By having the brick checkerwork at the uppermost part only, where it provides for a uniform distribution of the acid fed in, and for a finished heat exchange between it and the ascending gases, cracking or spalling is at least minimized, because, immediately upon entering the tower, the combustion gases are greatly reduced in temperature as a result of coming into con-

tact with a shower of acid. The arches are made massive because, even though the surface brick near the base of the tower crack and spall to some extent, those in the core remain sufficiently intact to support the weight above.

Acid Distribution

An acid distributor, consisting of a disk to which the acid is supplied at the center and having any number of equal-sized compartments at the rim, which are connected at their bottoms to sealed distributor pipes with heads of several feet above the tower top, has been found to furnish an equally divided and continuous-running feed, as the main supply is varied. The compartments are formed by the disk rim, by an outer circular rim and by equally spaced division walls which are radii of the circle. The acid delivered to the center spreads evenly in all directions and overflows the disk rim according to the spacing of the division walls. If the pipes are provided with sufficient head to force any sediment which might collect in an "S" bend seal to pass along with the acid, a regular, uniformly divided supply is assured.

"V" slots, weirs, or small holes, generally used for dividing in a variety of distributor systems and depending upon the care and judgment exercised by a towerman in poking or cleansing from the mud or débris furnished by dirty acid, are to be condemned when ease of operation is desired, particularly in view of the uncertainty as to whether, under the best of conditions, the streams can be equal in quantity.

It is important that the strong concentrator, in particular, should have a uniformly divided and continuous-running supply, since, should some part of the packing fail to receive its share of the acid, that part would become dry and overheated and, upon again receiving its quota, might be cracked and spalled. A poor distributing system might permit the acid to shift from part to part of the tower to such an extent as to require that the tower be repacked frequently.

Condensing Towers

When working normally, the gases leave the strong tower at about 240 deg. F. in a volume corresponding to the products of combustion from regular firebox practice, with the exception of the addition of the condensible vapors. Therefore they are not large in amount and do not require extensive condensing equipment to remove the acid evaporated. The two condensing towers are loosely packed because the acid fed to the concentrator may continuously furnish traces of organic matter to them, and an accumulation might fill the voids of tight packing.

The gases enter the top of the first condenser tower and travel from the base to an acid exhauster, from which they pass upwardly in the second tower. Since these towers do not have brick walls, they radiate heat freely, but they are cooled further by circulating a part of the distillate which has been brought down to ordinary temperature in coolers. For a production of 25 tons per day, the power required to run the acid fan is not over 3 hp. The distillate produced may average 40 deg. Bé., the strength being regulated to some degree by the amount of cool distillate which is circulated. Thus a material amount of water vapor is passed out of the tailstack.

The evaporating, or weak-acid, tower is constructed in a manner similar to the strong-acid concentrator, but is not connected to condensing apparatus because the effluent is not brought to a strength which permits the escape of acid with the water vapor.

The strong tower will require washing from time to time, the frequency depending upon the amount of dirt in the acid. This may have to be done as often as twice a month, but the operation is relatively simple and of short duration, in that it consists in turning on a larger acid stream for a period of 4 to 5 hours, so as to make a product of 58 to 60 deg. Bé. instead of 66 deg. Bé. The weak product so made may be delivered to the "partially concentrated" stock tanks, when, after the mud has settled out, the acid may be used along with that fed to the strong tower.

The packing in the strong tower will last in proportion as the bricks used are vitrified, and as care is exercised in maintaining uniform operating conditions but even should such efficient, economical and low-first-cost equipment as this require repacking in the course of a few years, it does not become a hardship, because there are only a few thousand bricks in the checker work and six men can do the job in about a week.

A tower layout, such as has been described, for producing about 25 tons of 66 deg. Bé. acid per day, may be put into commission under average conditions applying in January, 1922, for approximately $40,000. As industrial conditions improve, this cost may be reduced.

Denver, Colo.

Variety of Chemical Byproducts Tried as Wood Preservatives

A list of the various substances that have been used or suggested for preserving timber from decay would include a surprisingly large proportion of those known to industrial chemistry. Byproducts for which no use could be found have often taken their last stand as possible preservatives of wood. There have been sent to the U. S. Forest Products Laboratory for testing of their preservative qualities the condensed fumes of smelters, the waste liquors of pulp plants, the refuse of tanneries, the skimmed milk of creameries and a wide assortment of compounds under trade names. Very few materials have been found to have value as wood preservatives.

To preserve wood against decay a substance must first of all be poisonous to wood-destroying fungi. Decay in wood is not due to direct chemical action or action of the elements but is always the result of the activity of these plants which feed on the wood and thus destroy it. To prevent fungous infection, the preservative must be able to penetrate the wood thoroughly enough to form a continuous exterior shell of poisonous treated wood deeper than any surface checks which are likely to develop, and to retain its toxicity, or poisoning power, under service conditions.

Safety in handling and use is another important consideration. A wood preservative must not be a dangerous poison to men and animals, a highly flammable substance, or a material injurious to wood. If it seriously corrodes iron, steel or brass, its use is limited because of its action on the treating equipment and on bolts and metal fastenings in contact with the wood in service. Color, odor and effect on paint are sometimes of considerable importance.

Provided a preservative meets these requirements its cost, availability and uniformity will largely determine its usefulness.

Decomposition Processes Applicable to Certain Products Of Coal Carbonization

An Experimental Study in Which Mixed Xylenes Were Decomposed Under Varied Conditions of Temperature, Pressure and Atmosphere—Effects of Different Contact Surfaces—Identification of Many of the Important Decomposition Products

By M. J. Bradley* With S. W. Parr

THE extensive experimental work carried on in these laboratories on the coking of Illinois, Eastern bituminous, Utah, Canadian and many other coals has demonstrated the possibility of increasing the yield of tar oils approximately one hundred-fold, depending upon the variety of coal used in the low-temperature carbonizing process. The distillate obtained in this manner contains a large quantity of neutral, low-boiling, aromatic oils, some of which under normal commercial conditions have a limited application in the industries. For instance, xylene could be obtained in large quantities even under present conditions, if its industrial demand were such as to warrant the expense of recovery and purifying. This hydrocarbon, having a boiling range from 137 to 141 deg. C., has too low a vapor pressure to be an efficient motor fuel, but if by pyrogenic decomposition it can be converted into benzene, which boils at 80 deg. C., its value as a motor fuel is greatly increased. Xylene can also be decomposed in such a manner as to form higher boiling compounds, many being solids at ordinary temperatures. Anthracene and methyl-anthracenes can be obtained in this manner, but, by known methods, in small yields.

In this research an endeavor was made to find out the mode of decomposition and formation of the various products obtained from xylene in order to be able to increase the yields of the desired compounds, and if possible to use this knowledge in working over crude tar oils in order to obtain similar products. In the following experimental work some striking results were obtained which seemed to be directly opposed to those recorded by other investigators.[1] Pure xylene was passed through an electrically heated furnace, at various temperatures, under different pressures and in the presence of such contact surfaces as iron oxides, reduced iron, copper, tin, molybdenum, chromium, the alloy Illium, aluminum, nickel, cobalt, manganese, charcoal, pumice and refractory. The condensible compounds were collected, weighed and analyzed and the non-condensible measured and analyzed. The vapor condition inside of the furnace was varied by introducing, at the same time with the xylene, air, superheated steam, carbon dioxide, carbon monoxide, hydrogen, nitrogen or ethylene.

Apparatus Used in Experimental Work

The essential parts of the apparatus are shown in the photographs accompanying this paper. The complete outfit, being of a conventional type, requires little explanation, with the possible exception of the furnace. It was made by taking 6 ft. of 4-in. wrought-iron pipe, threading on flanges and thermocouple pockets and then having these joints acetylene-welded to insure having no leaks under conditions of high temperature and pressure. The caps were cast particularly for this furnace and extended 1½ in. into the end of the pipe and were fitted with three ¾-in. threaded openings leading into the furnace.

The pipe was thinly coated with alundum cement, wound in five sections, each having 36.5 ft. of nickel-chromium resistance wire, and again coated with cement. It was surrounded by a wooden box, 20 in. square and as long as the furnace, which contained the pulverized-asbestos and Sil-O-Cel insulation. Each heating element, when connected directly across the 110-volt line, permitted a maximum current of 20 amperes to pass through, but this could be reduced to 5 amperes by means of an external resistance connected in series at the switchboard. At no time was more than 10 amperes permitted to go through the heating elements. By this means the heat of the furnace could be kept constant at any desired temperature between 250 and 900 deg. C.

The top end was fitted with feed pipes for xylene, superheated steam and other gases, also with a pressure and reduced pressure gage. On the exit at the bottom end was a safety relief valve, or constant pressure valve, which could be adjusted to let the gases escape into the line leading to the gas meter at any desired pressure. This outfit has been operated at pressures as high as 180 lb. per square inch. The temperature was measured by means of a thermocouple. The cold junction was kept at zero by means of a Thermos bottle well and ice water, and the e.m.f. was read on a millivoltmeter which had been standardized at known temperatures.

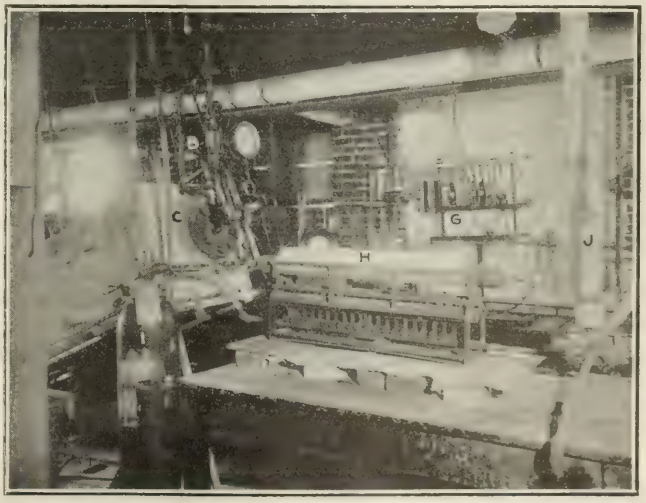

FIG. 1—UPPER END OF FURNACE

*An abstract of work carried out by M. J. Bradley in partial fulfillment for the degree of Doctor of Philosophy at the University of Illinois.

[1]In order to conserve space, no discussion of other investigations is included in this paper, but a list of articles on the pyrogenic reactions of aromatic hydrocarbons which appeared to be most important in connection with the present problem is given at the end.

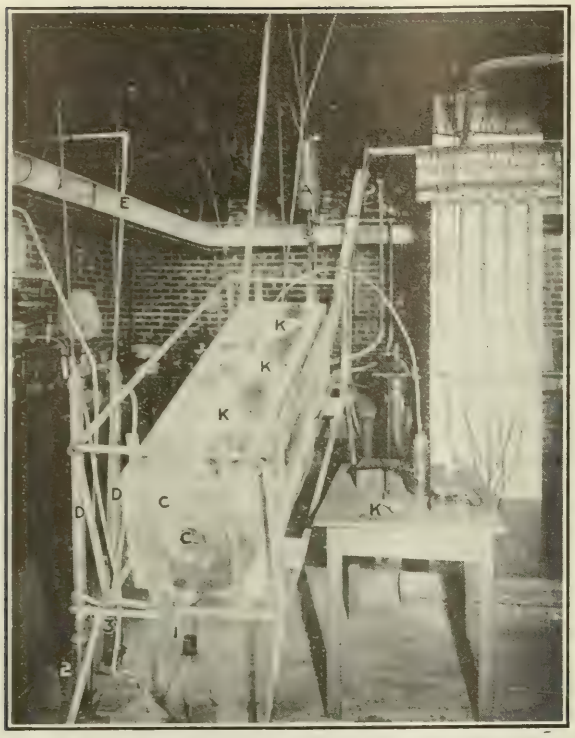

FIG. 2—LOWER END OF THE FURNACE

By this method the temperature could be read accurately within 4 or 5 deg. The thermocouple pockets *K* (see Figs. 1 and 2) extended into the middle of the furnace and thus gave the temperature of the area where the largest volume of vapors passed.

Method of Operation

The mechanical arrangement of the apparatus is apparent from the explanation of the progressive steps of a typical run. The xylene was placed in the reservoir *A* (Figs. 1 and 2), fed by means of a regulating valve through the sight-glass or bypass *B* into the upper end of the furnace *C*. Here also could be introduced gas, such as hydrogen, nitrogen, carbon dioxide or ethylene, from the cylinder *I* or steam from the high-pressure steam line *J* could be introduced through the gas-fired superheater *H*. Another attachment, not shown in the illustration, permitted the use of compressed air.

In passing down through *C* the vapors came in contact with the various contact surfaces used. The highest boiling condensate was collected in receiver *I*, the medium oils in No. 2, while the gases, after passing through the water-cooled condensers *D*, were scrubbed with heavy oil in receiver 3. The gas leaving receiver 3 passed through pipe *E* to be measured by the meter *F* and was then burned, or analyzed by means of the modified Orsat apparatus *G*.

When running under increased pressure, extra lengths of piping, fitted with a gate valve, were attached to the ends of the condensers. By keeping the lower valve closed and the upper one open, the condensate collected between them and could be easily removed, by closing the upper valve and opening the lower one, without causing any change in the pressure within the furnace.

Method of Analyzing Products

The condensible products were weighed, fractionated through a 6-in. wash column of glass beads until all the liquids boiling below 145 deg. C. were removed. The liquid boiling above 145 deg. C., designated in the following results as high-boiling product, was then transferred to an ordinary distilling flask and the fractionation continued until all but coke was driven over. These operations were carried out in electrically heated pot furnaces built to accommodate the particular flask used and maintained at a constant temperature by means of external resistances. Thus each furnace could be regulated so that no distillate would be driven over above a certain temperature. One furnace was used for each cut, up to 105 deg. C.; from 105 deg. C. to 130 deg. C.; from 130 deg. C. to 145 deg. C.; and finally one for the higher boiling compounds. This method saved much time, as it was possible to have several fractionating flasks going at the same time as the furnace and gas analyses.

The solids obtained from the high-boiling oils were purified and analyzed by a combination of various methods as described by Charlton (17), Clark (21), Cook (22) and others (see bibliography at end of article). Partial separation was obtained by making the distillation cuts at various temperatures and then lowering the temperature sufficiently to freeze out the solids. In some cases steam distillation, fractional solution, class reactions and other methods were used to advantage, but these operations are too long to be described in this paper.

The products not removed in the scrubbing process were measured by a standard wet meter and then burned. The sample taken for analysis was collected before passing through the meter. The gases were analyzed by means of a modified Orsat apparatus constructed by the author. It is shown in Fig. 3 with the oxygen and nitrogen reservoir permanently attached to the manifold ready for use and the furnace removed, showing the copper oxide tube. Another modification of this apparatus is shown in a text[2] describing a number of processes and apparatus developed in this laboratory. The carbon dioxide was removed with 35 per cent KOH solution; oxygen by potassium pyrogallate; acetylene by ammoniacal silver chloride; ethylene by bromine water; aromatics by 20 per cent fuming sul-

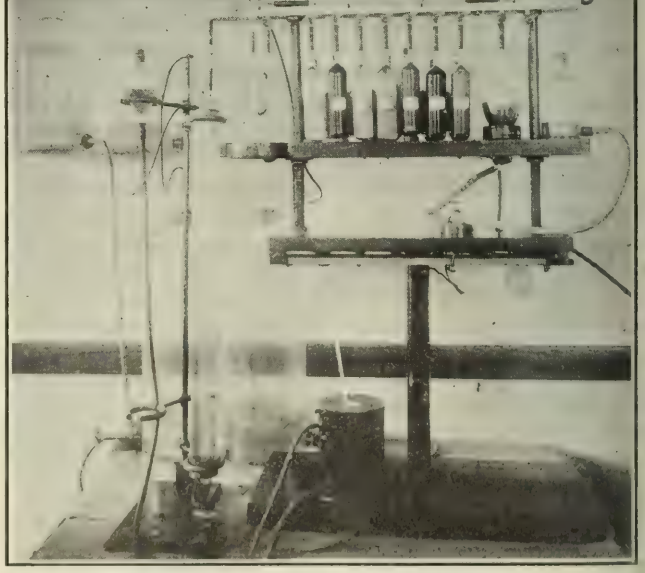

FIG. 3—MODIFIED ORSAT GAS ANALYZING APPARATUS, SHOWING THE WATER-COOLED FURNACE REMOVED

phuric acid; hydrogen and carbon monoxide by combustion with copper and ceric oxides; ethane and methane by slow combustion by means of a platinum coil in pure oxygen; and the nitrogen was estimated by difference.

The gas sample was taken in at the top of the burette and measured at atmospheric pressure by means of twin burettes joined at bottom. The copper oxide tube was made of Pyrex glass and contained about 30 grams of granular copper oxide which passed through a 10-mesh and remained on a 20-mesh screen. To this was added about 0.9 gram of finely powdered ceric oxide, which seemed to activate the copper oxide and greatly to hasten the combustion of hydrogen. In fact, where the carbon monoxide content was low or previously removed by acid cuprous chloride, 70 to 80 c.c. of hydrogen could easily be completely burned in 5 minutes. In the presence of considerable quantities of carbon monoxide the combustion was slower. The combustion tube was frequently oxidized with pure oxygen.

The absorption pipettes contained thin-walled glass tubing to give surface and speed up the absorption. The slow combustion pipette for ethane and methane was made from a 300-c.c. thick-walled Kjeldahl Pyrex flask, which proved very satisfactory. The temperature of the platinum coil was regulated by means of a chromel resistance in series shown on the front of the stand. It is realized that an exact separation of acetylene and ethylene cannot be obtained in the above manner, but by leaving the gases in contact with the ammoniacal silver chloride solution during a constant time interval in each analysis, a relative idea of the two constituents can be obtained. The complete analysis could be made in this apparatus in less than 30 minutes.

Specification of the Hydrocarbons

The mixed xylene, which was the commercial product such as is usually marketed in 10-gal. cans, was used in the major portion of this work. After redistilling, it was water-white, contained no suspended material, was free from moisture, had no foreign odor, practically all distilled over between 137 and 142 deg. C. and had a specific gravity of 0.8664 at 15.5 deg. C.

The benzene, toluene and naphthalene used were the commercial product in stock in the chemistry storeroom. They were not analyzed or purified in any manner, as only a few runs were made with them to compare with the results obtained on xylene under similar conditions.

The results on the decomposition of xylene are summarized in Table I and the outstanding features are discussed briefly in the comments on each series.

Results of Tests

Each run selected for use in the table is a typical result obtained in a series of eight to twelve similar runs made while the furnace was heated up and with similar conditions inside the furnace—that is, as to contact surfaces and lining. The results are given as obtained for various temperature ranges, different pressures and under the influence of other gases which were introduced into the furnace at the same time as the xylene. The amount of xylene used was 1,000, 500 or 200 grams and was fed through the furnace in 2-hour or 1-hour periods. The sample of gas for analysis was taken when the run was about three-quarters completed. The loss in per cent is given on the basis of the weight of the original xylene; the different fractions of the condensate and coke obtained are given on the same basis. The results tabulated for fractions boiling above 145 deg. C. are not given on a particular run, but on heavy boiling product obtained in several runs in the same series.

A number of preliminary runs between 200 and 600 deg. C. at 50 deg. C. intervals were made on 1,000-gram samples of xylene to see if the iron surface of the furnace would promote any reactions. The loss was less than 1 per cent and the volume of gas was so small that it was not analyzed; the condensate was practically unchanged xylene.

Charcoal as a Catalyst

For series 1, No. 26 being a sample, 2 kg. of wood charcoal, cut in small cubes about $\frac{3}{4}$ in. square, were placed inside of the furnace. The first run was made at 250 deg. C., but no appreciable reactions were noted. As the temperature rose, more gas was given off and contained increasing amounts of CO. Xylene seemed very stable under these conditions up to temperatures above 650 deg. C., when about one-fourth of it was lost. At lower temperatures considerable ethane was found in the escaping gas, while the proportion of methane was small. At 600 deg. C. the ethane content was at its maximum, about 7.5 per cent, and with 20.0 per cent of methane present, but as the temperature rose, the ethane decreased rapidly, while the percentage of methane increased. On the conclusion of the series, considerable carbon, from the decomposition of xylene, was found adhering to the furnace walls.

Before commencing series 2, the furnace was cleaned by means of a wire brush and 2 kg. of new charcoal cubes inserted. To insure against leaks, the furnace was subjected to 125 lb. pressure of live steam before heating up. This steaming of the charcoal seemed to activate it so the reactions commenced at lower temperatures, for instance at 550 deg. C. over 20 per cent ethane was found in the outgoing gas and about 25 per cent of the condensate was toluene. At 600 deg. C. the ethane had disappeared and the toluene fraction decreased, while the hydrogen and methane were greatly increased. During the run at 700 deg. C. the temperature of the furnace fell rapidly and a great increase in the volume of gases took place. The furnace became activated in such a manner that the xylene was completely decomposed into gaseous products and amorphous carbon. Run 33 summarizes the results. Several other runs at lower temperatures gave similar products; even introducing hydrogen from a cylinder at various pressures up to 150 lb. did not stabilize the reactions in such a way as to obtain any condensate. The xylene was completely decomposed into hydrogen, methane and carbon.

Effects of Oxygen and Hydrogen

Before beginning series 3 about 8 cu.ft. of air was passed through the heated furnace; approximately 14 per cent of CO_2 was found in the issuing gases. The air poisoned or deadened the activity of the furnace, with the result that 44 per cent of the xylene was unchanged at 500 deg. C. The air was discontinued during run 50. In this series it was found that charcoal, when heated to 700 deg. C. under reducing conditions and then cooled out of contact with air, would, at ordinary temperatures, take up air readily. On again heating, the oxygen came off as carbon oxides, the dioxide at lower and the monoxide at higher temperatures. It was extremely difficult to remove the oxygen even at 700 deg. C. in the presence of hydrogen, diminishing amounts being given off after several days' treatment.

Before series 4 the furnace had been thoroughly cleaned of carbon and new charcoal added. While heating up it was kept under reducing conditions with hydrogen from a cylinder. During this series considerable toluene was formed, especially at 650, 700 and 750 deg. C. At the latter temperature, under excess hydrogen from the cylinder, a yield of 56 per cent was obtained, while without the hydrogen only 43 to 45 per cent was obtainable. In this case hydrogen seemed to stabilize rather than promote the decomposition of toluene. Superheated steam deadened the activity of the furnace in such a way as to stabilize the xylene passing through, although after steaming and then reducing for a short time the furnace became activated in such a manner as to decompose the xylene completely. This was also found to be true without any charcoal in the furnace. That is, the iron surfaces could be freshly oxidized or activated by means of steam when heated between 600 and 790 deg. C. and after reducing slightly became activated so that the xylene was completely decomposed into carbon, hydrogen and methane. Run 61 shows the results of the first run after passing superheated steam through the furnace; after reducing with hydrogen for a short time, the xylene was completely decomposed, but could be partly stabilized by passing CO or CO_2 into the furnace at the same time as the hydrocarbon. Hydrogen even at 140 lb. pressure did not stabilize any of the liquid products, once the furnace was in this activated condition. The carbon deposited was intensely black and fluffy, contained some small percentage of liquid hydrocarbon and about 11 per cent of iron, which was found to be a mixture of the magnetic oxide and other oxides, along with very small particles of finely divided metallic iron. It was impossible to tell from these results whether it was the iron or the charcoal surfaces which was causing the complete decomposition of the liquid hydrocarbons.

Effect of Metal Furnace Wall

In series 5 a lining tube of No. 18 sheet copper was placed snugly in the furnace so that no iron surfaces were left exposed. Copper seemed to have a tendency to decompose xylene into lower rather than higher boiling compounds, as shown in run 78. Oxidizing the copper made it somewhat more active, but on reducing it again complete decomposition of the xylene did not take place. What decomposition did take place seemed to form liquid and gaseous products rather than amorphous carbon, which was formed only in extremely small amounts.

In series 6 the furnace was copper lined and contained 2½ kg. of charcoal cubes. Typical results obtained in this series is shown in run 88. The reactions below 600 deg. C. were unimportant, but as the temperature rose the loss became greater. The loss was cut down somewhat by introducing hydrogen into the furnace, which appeared to stabilize and increase the toluene fraction. However, it was found impossible to activate the furnace and charcoal as described for series 2 and 3.

In series 7 the furnace was copper lined and the contact surface consisted of 3½ kg. of oxidized Illium turnings, mechanically mixed among small pieces of pumice. These runs demonstrated that around 700 deg. C. the decomposition of xylene was greatest and giving the maximum quantity of the lower boiling fractions.

Series 8 was made over small pieces of pumice which had been dipped in nickel nitrate and then reduced at 500 deg. C. with hydrogen. This was to get the metal in a finely divided condition and over as much surface as possible. Several runs were made between 500 and 800 deg. C., run 104 being a sample. Nickel under these conditions did not promote the formation of liquid products, but rather favored complete decomposition of the hydrocarbons into hydrogen, methane and carbon. In fact, the deposited carbon soon filled the furnace so that the series had to be discontinued. At this time the copper lining was found to have become broken in several places, leaving iron surfaces exposed, which no doubt had influenced the reactions.

Before commencing series 9 the furnace was relined with tinned copper, the tin surface being on the inside. Run 113 gives a typical example of results obtained. The series seemed to indicate that in the neighborhood of 700 deg. C. tin promoted the formation of low-boiling liquids. No other contact materials were in the furnace during these runs.

Effect of Nickel, Molybdenum and Cobalt

Series 10 was run through the tinned-copper lining and using 2½ kg. of charcoal cubes which had been dipped in a thin paste of nickel oxide and dried at 110 deg. C. In this case the nickel oxide and furnace were not reduced before commencing the runs. The results obtained were similar to those of the iron-charcoal

eries—that is, the xylene tended to be completely broken down into carbon, hydrogen and methane. Even at as low a temperature as 450 deg. C., 83.5 per cent total loss was obtained. During run 125 hydrogen was introduced at 15 lb. pressure, but did not stabilize any of the liquid hydrocarbons. Small amounts of water were collected in the condensate in every run. The furnace was soon choked up by the deposited carbon. During this series practically all the tin surface scaled off the copper lining.

The next series, No. 11, was run in the copper-lined furnace after over ½ lb. of metallic molybdenum powder had been scattered among the small pieces of pumice stone. As in the preceding series, considerable moisture was collected in the condensate. No appreciable decomposition of the xylene took place below 600 deg. C., but above this temperature the reactions greatly favored the formation of benzene and of methane rather than hydrogen and carbon. Run 133 gives a fair idea of results obtained.

Series 13 was run with the copper-lined furnace containing 5 kg. of 1-cm. cobalt cubes. To reduce all the oxide surfaces the furnace was heated to 500 deg. C. and maintained under 60 lb. pressure of hydrogen for several hours. Even after this treatment moisture was collected in the condensate. Cobalt promotes the decomposition of xylene at low temperatures; even at 450 deg. C. about 35 per cent was lost, and at 550 to 575 deg. C. considerable toluene was formed, as shown in run 142.

Manganese and Aluminum

In series 14 manganese in a fine powder was scattered among the small pieces of pumice stone. This metal promoted the decomposition of xylene at lower temperatures than any tried previously and the products formed were liquid rather than gaseous. Run 151 indicates the decomposition products obtained.

In series 15, 440 grams of aluminum powder was scattered among the small pieces of pumice stone and several runs were made at various temperatures. Below 600 deg. C. very little decomposition of xylene took place, but what was changed went to hydrogen and deposited carbon. Run 163, at 680 deg. C., indicates that aluminum does not favor the formation of higher boiling compounds from xylene. It should be mentioned that the copper lining during this series had given way in several places so that some iron was exposed.

Before series 16 the copper lining was removed from the furnace, the latter cleaned by means of a wire brush, reduced while hot with hydrogen and when cold was coated with a lining made by mixing 80 per cent Hytempite with 20 per cent alundum cement. After drying and baking, several runs were made without other contact surfaces. Under these conditions the xylene did not decompose much below 600 deg. C., while above this temperature liquids rather than gaseous compounds were formed. Run 167 gives results at 550 deg. C. and shows the amount of ethylene formed.

Cracking in Atmosphere of Ethylene

For series 20 a cylinder of commercial ethylene was connected to the upper end of the furnace. The refractory lining was in good repair and no other materials were introduced for contact surfaces. The preliminary runs introducing ethylene at 45 lb. pressure into the furnace gave some interesting data regarding the stability of ethane, methane and ethylene under these conditions. At 415 deg. C. the waste gases contained 89.4 per cent of ethylene, no ethane and 8.5 per cent of methane; at 475 deg. C. it contained 73.9 per cent of ethylene, 4.6 per cent of ethane and 10.0 per cent of methane. The maximum amount of ethane was obtained at 500 deg. C.; the methane increased with temperature, and at 675 deg. C. the outgoing gases contained 84.1 per cent of methane. Below 475 deg. C. very little decomposition of xylene took place, the loss being less than 5 per cent. In the runs below 475 deg. C. there was always a gain in weight in the liquid condensate, although little xylene was decomposed. This was found to be due to the xylene dissolving considerable volumes of the ethylene, which was readily given off when redistilling. Around 600 deg. C. the furnace decomposed xylene and ethylene very rapidly, the latter going principally to methane. In order to keep the furnace atmosphere mostly ethylene, the pressure outlet gage was set at 2 lb. and the ethylene introduced into the furnace very rapidly. Under these conditions the maximum yield of high-boiling compounds was obtained. The results are given in run 286. Many other runs under various conditions of pressure, rates of feed and gaseous atmospheres were made, but the percentage of higher boiling compounds were lower than in the run tabulated.

In series 21 the refractory-lined furnace was found to decompose xylene as described for series 16. It was now desirable to see if the lower boiling liquids could be stabilized by deliberate control of the gaseous atmosphere inside the furnace. In run 287 the furnace was maintained under 125 lb. pressure with hydrogen from a cylinder while the xylene was being introduced. The results indicate that the major portion of the xylene was decomposed into lower boiling liquids.

In series 25 the low-boiling liquids were slightly increased by increasing the hydrogen concentration in the furnace. The maximum yield is shown in run 288. This result is calculated from the weight of xylene used, while by referring to the equation $C_8H_{10} + 2H_2 \rightleftarrows 2CH_4 + C_6H_6$, it is evident that this would equal about 93.7 per cent of the possible theoretical yield. The carbon deposited in these runs was very different in appearance from that described previously. It was a metallic gray color and was granular or sandy, while the other deposits had been intensely black and slightly oily.

Runs Using Benzene, Toluene and Naphthalene

The runs with benzene were made through the iron furnace containing 2½ kg. of charcoal, the purpose being to try to check the results of Cobb and Hollings (23). They found that benzene passing through coke heated to 800 deg. C. could be entirely stabilized by means of excess hydrogen. In these experiments it was found that when the charcoal and furnace were activated it was impossible to stabilize the benzene even at 500 deg. C. Pressures as high as 125 lb. of hydrogen per square inch were used. On the other hand, if the charcoal and furnace had been treated with superheated steam, air or carbon dioxide, benzene could be entirely stabilized at temperatures as high as 800 deg. C. with very small pressures of hydrogen.

Cobb and Hollings (23) had found that when toluene was passed through red hot coke it was more stable alone than in the presence of excess hydrogen—that is, hydrogen promoted the decomposition of toluene into benzene and methane. In series 4 hydrogen was found to increase the toluene fraction slightly. Pure toluene was

used under similar conditions and found to be somewhat more stable in the presence of hydrogen, except when the furnace was in the activated condition, when it was entirely decomposed with or without hydrogen.

In making the runs with naphthalene, it was preheated in an electrically heated retort connected to the upper end of the furnace. The naphthalene vapors were carried into the furnace by means of the gases which were bubbled through. It was noticed that practically as soon as the run commenced the temperature of the furnace dropped. Even when the current passing through the heating elements was materially increased, the temperature fell slowly. This would indicate that the reactions taking place inside the furnace were absorbing considerable heat. Another feature, particularly noticeable in the nitrogen run, was that the gas recovered did not equal the amount passed into the furnace from the cylinder, even with the addition of the gas from decomposition of the naphthalene. The charcoal may be partly responsible for this result.

In the runs using carbon dioxide as the carrying gas the product contained a heavy, black, high-boiling oil, some free carbon and a very light, fluffy, red material with very little odor of naphthalene. With hydrogen the product was dark gray, containing also traces of the light reddish material. The product from the nitrogen runs was a compact greenish color and from carbon monoxide the reddish fluffy material formed the bulk of the recovery.

The bulk of the recovered product was naphthalene, with small amounts of benzerythrene and α-methyl-naphthalene. A considerable amount of β-β-dinaphthyl, m.p. 187-8 deg. C., was obtained and identified by the picrate, m.p. 183 deg. C. The α-α and α-β forms were present in very small amounts.

Gaseous Products Synthesized

The process of decomposition of hydrocarbons can never be regarded as a simple effect of heat, independent of contact surfaces and the gaseous atmosphere in which it is conducted. The way in which we were able to modify the results of decomposition in various directions was by the deliberate control of these two factors. The gaseous products obtained in these experiments were extremely important and played as important a part in the final products as the gas introduced. Their effects can be considered from two standpoints—mechanical and chemical. An inert gas, like nitrogen, would not enter directly into chemical reaction under these conditions, but would play a very important part by washing the products of decomposition from the surface of the contact material, assist their volatilization by lowering their concentration in the vapor phase, and hurry them away from the region of decomposition. In the case of hydrogen, being much lighter, it has a greater diffusing power, the molecules travel at a higher speed and thus penetrate small areas where the larger gas molecules never reach. The all-important action of hydrogen, however, is chemical. It tends to reduce the single ring benzene hydrocarbons to benzene itself. A similar action may be inferred, as is very probable, on the attached groups of more complicated ring structures resulting in the formation of naphthalene and anthracene. It seems that this was the part played by hydrogen in the majority of the experiments carried out. However, other factors must be able to modify this tendency of hydrogen, because in the experiments giving the largest yields of the toluene fraction it was found possible to increase this fraction by introducing hydrogen from a cylinder. It was possible to change the production of hydrogen in these experiments by changing the temperature or the activity of the furnace.

Methane could also be produced in varying quantities, depending upon the furnace conditions. Bone and Coward (24) concluded that methane decomposes chiefly directly into hydrogen and carbon, the process being reversible and a surface phenomenon at least up to 1,200 deg. C. At the temperature these experiments were run methane is practically stable and its chemical reaction would be negligible, but its mechanical action would be very important, as in the case of nitrogen.

The carbon dioxide formed was in small quantities and was always in equilibrium with carbon monoxide. They seemed to deaden or poison the activity of the furnace, although it is possible CO_2 caused partial combustion.

Acetylene was formed in small quantities and although many investigators claim that the building up process is through the ability of acetylene to polymerize, it was concluded from these experiments that acetylene played a very small part. At higher temperatures it was more likely to be decomposed to carbon and hydrogen than to be built up.

Ethylene Formation

The production of ethylene in these reactions was very desirable, because it was noticed that wherever the percentage of ethylene in the outgoing gas approximated 3 or 4 per cent, the yields of the higher boiling compounds were appreciably increased. In general, it was found that ethylene decomposed into a mixture of ethane and methane in the neighborhood of 500 deg. C. Above 500 deg. C. the ethane content gradually decreased and around 650 deg. C. disappeared entirely with a resultant increase in methane. Ethylene seems to be able to decompose in several ways, which no doubt explains its usefulness in the building up process.

Bone and Coward (24) concluded that the primary action of heat on ethylene is to eliminate hydrogen. The residue $\equiv CH$ thus formed may decompose or be hydrogenated to methane, or it may unite with another such residue to form acetylene. Hollings and Cobb (23) found that at lower temperatures, around 800 deg. C., it decomposed into methane and acetylene, while at higher temperatures it went into methane and hydrogen.

In some of these experiments as high as 15 per cent of the waste gas was found to be ethane. It was also found that very little ethane was formed below 475 deg. C. and that it was all practically decomposed at 700 to 725 deg. C., except in the presence of steam, which seemed to stabilize it at slightly higher temperatures. These temperatures are far lower than found by Hollings and Cobb (23), who found that the decomposition of ethane was rapid but not complete in 46 seconds at 800 deg. C. At 1,100 deg. C. only 88 per cent was decomposed, the chief products being ethylene and methane. No doubt the molecular decomposition of ethane played an important part in these experiments. According to J. J. Thomson (25), such residues as $\equiv CH$, $=CH_2$ and $—CH_3$ may exist momentarily in the free state. The four possibilities open to the residue $= CH_2$ are: (1) To form ethylene by uniting with another similar residue; (2) to break down into carbon and hydrogen; (3) to be hydrogenated

to methane; (4) to attach to some heavier molecular formation—a partial decomposition of the benzene nucleus or homologs.

The above is only a partial list of the gaseous constituents in the furnace atmosphere during decomposition; undoubtedly many more complex groups or radicles from the higher boiling compounds exerted an important influence on the decomposition processes.

Liquid Hydrocarbons Identified

Some of the liquid hydrocarbons which were purified and definitely identified by physical contents or known derivatives are listed below. Other compounds were obtained but have not been identified.

n-Hexane, b.p. 68 deg. C., was obtained in the ethylene series of runs in considerable quantities along with an unsaturated hydrocarbon, which had very similar physical properties, probably hexylene. They were partly separated by the usual methods and the last traces of the unsaturated compound were removed by selenium oxychloride. This reagent reacts too violently to use, however, where any considerable quantity of the unsaturated compound is present.

Cyclo Hexane, b.p. 80 deg. C., was obtained in small quantities, and after a partial separation from benzene, was purified by the above reagent. However, a solution of benzene in selenium oxychloride will readily dissolve cyclohexane. In cases where only traces of benzene were present the separation was rapid and complete.

Benzene, b.p. 80.5 deg. C., was obtained in several runs. The maximum yield obtained was 93.0 per cent of the possible theoretical.

Toluene, b.p. 110 deg. C., was obtained in many of the runs over charcoal. The maximum yield of the crude product was about 66.0 per cent of the possible theoretical.

α- and β-*Methyl-Naphthalenes*, b.p. 240-3 deg. C., were identified by the picrate, m.p 112 deg. C.

Di-Tolyls (mixed), b.p, 275-8 deg. C., were identified by the acid derivatives. They were oxidized by prolonged boiling in chromic and glacial acetic acids.

1.2.*Dimethyl-Naphthalene*, b.p. 262-4 deg. C., was identified by the picrate.

Diphenyl-Ethane, b.p. 286 deg. C., was obtained in small quantities.

Some of the Solids Obtained

The solids synthesized were numerous and complex. In a single series of runs the high-boiling constituents were very similar, but in different series the variation was marked. In the series using cobalt and manganese the high-boiling oils contained a larger percentage of solids containing anthracene. The partial list follows:

Diphenyl, m.p. 70 deg. C., was obtained in considerable quantities in the fraction boiling from 340 to 255 deg. C. On standing, it settled out as a white solid. This compound could come from two benzene molecules with the liberation of hydrogen. Dufton and Cobb (18) have proved this to be a reversible reaction by passing diphenyl and hydrogen through a hot silica tube and producing benzene.

Naphthalene, m.p. 80 deg. C., was obtained in considerable quantities, as closely as could be determined, in approximately 4 per cent yields on the original xylene used. In view of the conflicting reports in the literature concerning the formation of naphthalene at low temperatures and from similar liquids, toluene especially, particular care was taken in the purification and identification of this compound. The presence of stilbene may give a clue to its formation.

Phenanthrene, m.p 98-100 deg. C., was obtained in small yields. It was difficult to oxidize, but the picrate was easily obtained.

Stilbene, m.p. 124 deg. C., was found in small quantities; apparently it had been mostly condensed to naphthalene.

Pyrene, m.p. 145-7 deg. C., was identified by the picrate, m.p. 220 deg. C.

Methyl-Anthracene, m.p. 200-5 deg. C., was obtained in good yields. Both alpha and beta forms were present and were separated by means of the methyl-anthracene-carbonic acids, which have considerable difference in the melting point temperature.

p-Diphenyl-Benzene, m.p. 207 deg. C., was also formed.

Anthracene, m.p. 212-14 deg. C., was formed in considerable yields. It was rather difficult to purify it.

2.3.*Dimethyl-Anthracene*, m.p. 244-6 deg. C., was purified and identified by the quinone, m.p. 180-2 deg. C.

Chrysene, m.p. 248-50 deg. C., was obtained in small amounts in the runs with ethylene and xylene under high pressures.

Another compound which has been separated is similar to asphaltenes in its appearance, behavior toward solvents, especially ether and hexane, and contains sulphur. The sulphur must have come from the contact surfaces inside the furnace.

Summary and Conclusions

Some of the more important results as indicated by the foregoing investigation are given in the following summary:

1. Mixed xylenes were decomposed by heat and contact surfaces, under the stabilizing influence of hydrogen and methane, almost theoretically into benzene and methane. Sixty-nine per cent of the original xylene was converted into crude benzene, which boiled below 100 deg. C. This is approximately 94.0 per cent of the possible theoretical.

2. At slightly lower temperatures, under the same condition of contact surfaces but in a gaseous atmosphere in which ethylene greatly predominated, 77 per cent of the mixed xylenes were built up into higher boiling compounds, the majority of which were solids at ordinary temperatures.

3. Mixed xylenes, under other conditions of temperature and contact surfaces, were converted into crude toluene in quantities approximating 64.0 per cent of the theoretical.

4. Mixed xylenes, under the influence of heat and iron surfaces, were decomposed quantitatively into amorphous carbon and gaseous products. Metallic oxide surfaces, especially after being slightly reduced at temperatures where they decompose xylene freely, accelerate this reaction. Small particles of iron oxides and reduced iron were found in the deposited carbon.

5. The reduced metallic surfaces, or freshly oxidized surfaces at the same temperature are much less reactive and tend to promote partial decomposition.

6. Non-metallic substances such as charcoal, pumice or refractory material at like temperatures tend to decompose xylenes into unsaturated and higher boiling compounds. The decomposition to carbon is materially lessened.

7. Activation of heated iron and carbon surfaces could be induced by treating with superheated steam during a short period and afterward slightly reducing with hydrogen.

8. A deadening effect, opposite in characteristics to the above, was caused when carbon dioxide, carbon monoxide, air or superheated steam was passed through the activated furnace. This condition seemed to be the same, as is ordinarily described, as poisoning of the catalyzer. Under these conditions the liquid hydrocarbons were most stable.

9. Contact surfaces are very important to hydrogenation and dehydrogenation of aromatic hydrocarbons.

10. The gaseous atmosphere in which pyrogenic decomposition takes place exerts an extremely important influence on the yields and products of decomposition. Gases like methane and nitrogen between temperatures of 600 to 700 deg. C. have mostly a mechanical action. Ethylene, acetylene, hydrogen and ethane between the same temperatures have also a mechanical bearing on the end products, but their all-important action is chem-

ical. Ethylene, acetylene and ethane were found to be entirely decomposed at temperatures above 725 deg. C.

11. The decomposition of ethylene was controlled so that practically pure methane or mixtures of methane and ethane were obtained as end products.

12. Pressure under some conditions favors molecular condensation, particularly if the pressure is made up of unsaturated gases. In other cases, where the pressure was made up by hydrogen, it caused the decomposition of the heavier molecules into the single ring compounds. Pressure in all cases lessened the percentage of unsaturated hydrocarbons in the final products.

13. Decomposition of hydrocarbons increases with rise in temperature, the larger molecules being less stable than the smaller ones at temperatures above 700 deg. C. The lower the temperature at which decomposition takes place the more economical the reaction. Lower temperatures can be used in the presence of activated surfaces.

Use of Bentonite in De-inking of Newspapers Gives Promise of Forest Conservation

Although the de-inking and re-use of old magazines has been practiced for a long time, it has never been possible to apply the process to the recovery of old newspapers, because the strong alkaline solutions used in the process and the subsequent bleaching operation discolor any pulp containing ground wood. These solutions might be reduced in strength and temperature so as not to discolor the pulp and still serve to dissolve the varnish from the ink and free the carbon black. But the carbon particles would then collect in masses which would not pass through the washing screen or would remain enmeshed with the paper fibers. It is therefore necessary to provide some finely divided, colloidal carrying agent in the wash water which will help gather up the carbon and carry it off. Clays and talcs are used for this purpose, but ordinarily they are so coarse that they need to be peptized, or broken up, by strong alkalis at high temperatures before they are effective. It is this requirement that has made it necessary to use solutions in the de-inking process of such strength that they would discolor the ground-wood pulp of which newspaper is made.

Experiments have recently been conducted by the Forest Products Laboratory at Madison, Wis., using bentonite, a very fine cream-colored clay found in Wyoming, as a de-inking agent. Bentonite occurs in finer particles than any other natural mineral substance, and will go into colloidal suspension in water without the aid of strong alkalis. In preliminary de-inking runs made on old newspapers at the Forest Products Laboratory, bentonite was used with an alkali solution just strong enough to loosen the ink without discoloring the paper. It was found that the bentonite particles were so small that they could gather up the freed carbon and still pass through the ordinary washing screen. In the experimental runs, paper fiber matted on the screen and tended to prevent thorough washing; but even with this difficulty a sheet almost equal in quality to the original was obtained.

De-inking trials made later at a Minnesota paper mill, using ordinary paper-making equipment except for a special washing screen, show that the process can be carried out on a commercial scale to produce a sheet which can compete in the open market with standard news.

From 2,500 lb. of old newspapers 2,000 lb. can be recovered by the new de-inking process. In Chicago alone, it is estimated, 325 tons of waste newspapers daily might be economically collected and converted into approximately 260 tons of clean paper ready for reprinting. This would mean a daily saving of the cut on 97 acres of 100-year old spruce wood. The total saving in pulpwood which appears possible through the erection of newspaper de-inking mills in metropolitan centers is equivalent to the cut on 275,000 acres of densely stocked spruce forests yearly.

Wood-Pulp Production and Sales in Sweden

Consul General D. I. Murphy reports that the Swedish output of sulphite cellulose for the first 4 months of the present year, according to estimates from the Wood Pulp Association, amounted to 70 per cent of the normal capacity of the factories.

During this period 75,000 tons was sold, although prices were low and unsatisfactory. Prices recently have been stable, bleached sulphite being quoted at $80.43 to $85.79 per ton; easy-bleaching sulphite, $50.94 to $56.30 per ton; and strong sulphite, $38.87 to $53.61 per ton.

The production of sulphate pulp from January to April of this year was 73½ per cent of normal, or at the rate of about 28,000 tons per year. The strikes at the sawmills throughout northern Sweden, upon which the sulphate mills depend for their supplies, have contributed to the reduction of the output. Sales have recently been reported, quotations being from $52.28 to $54.93 per ton both for easy-bleaching and strong sulphate.

Mechanical pulp production during the January-April period of the present year amounted to about 75 per cent of the normal output. Quotations at present are firm at $30.29 to $33.51 per ton, dry pulp, but there appear to have been no sales of wet mechanical pulp.

Failure to Give Notice of Defects Under Provision of Contract Constitutes Acceptance

From Georgia comes an action at law brought by the York Manufacturing Co. against the South Atlantic Packing & Provision Co. to recover the price of certain ice-producing machinery installed for it under written contract. The machinery was to be affixed to and used with certain other machinery of the defendant, for the purpose of connecting a distilled-water ice plant into a raw-water ice plant. The contract contained necessary specifications and two guaranties were included as follows:

(1) That the plant when changed as specified will be capable of producing 100 tons of merchantable raw-water ice per day of 24 hours when in full and continuous operation according to instructions.

(2) That the coal consumption of this plant when producing 100 tons of ice per 24 hours would be not less than a ratio of 16 tons of ice per ton of 14,000 B.t.u. coal burned, based on the guaranteed boiler evaporation of 9 lb. of water per pound of coal with steam at 185 lb. and 160 deg. superheat at boiler.

The guaranty of quality of ice was based on water being taken from well known as No. 3, which had been tested.

Plaintiff Agreed to Remedy Defects if Notified Within 30 Days

The contract also provided that when plant was ready for charging written notice should be furnished to defendant of that fact and that if for a period of 30 days thereafter the defendant should fail to notify plaintiff in writing of any claim that the said machinery, apparatus or plant as furnished did not fulfill the terms and requirements of the contract, this fact would be taken as an acknowledgment by the purchaser that they did fulfill all requirements and should consistute a complete acceptance of the same as fulfilling all the terms and requirements of the contract. If such notice of failure was given within 30 days, the plaintiff was to remedy any such defects.

Defendant Failed to Give Notice Within Specified Time

It appears that no objections to the plant as completed were given within 30 days thereafter. Yet defendant pleaded in answer to the suit that the plant failed to produce 16 tons of ice to 1 ton of coal, 14,000 B.t.u., and that the plant failed to produce 100 tons of merchantable ice in 24 hours' continuous operation.

The District Court excluded all testimony offered to show that the plant did not comply in all respects with the contract and did not fulfill its terms and requirements, on the ground that defendant, having failed to give notice of such defects and failures within 30 days after receiving notice that the plant was erected ready to charge, had under the terms of the contract accepted said plant as fully complying with said contract and its guaranties and could not thereafter make such denial.

The United States Circuit Court of Appeals (276 Federal, 509) has upheld the District Court on this point, holding the 30-day provision valid and enforceable; and a failure to give such notice within 30 days after completion of plant was held a complete acceptance of said plant, precluding defendant from claiming breach of a warranty that plant would produce a stated quantity of ice per ton of coal consumed.

Contracts Requiring Return of Acetylene Containers Held Not in Restraint of Trade

Contracts under which tanks are furnished to purchasers of acteylene gas to be returned and refilled exclusively by the original manufacturer are not unconscionable nor in restraint of trade, in violation of the Clayton act of Oct. 15, 1914, section 3 (Comp. St., par. 8835c), says the United States Circuit Court of Appeals, affirming a decree of the District Court in favor of the Prest-O-Lite Co. in a suit in equity against the Auto Acetylene Co. (276 Fed., 537.)

The Prest-O-Lite Co. has for many years been engaged in generating, storing and distributing acetylene gas for use in automobile lighting and in welding. Its gas is stored in portable steel cylinders lined with asbestos or other porous material, which absorbs a quantity of acetone, which, in turn, is saturated with acetylene gas introduced under pressure, the outflow for consumption being valve controlled. The entire package so filled is furnished the consumer in the first instance. When the tank is consumed, the tank is accepted in exchange for a package fully charged by the company. It appears that this company has had much litigation in protecting itself and its product against unfair competition.

Contracts With Welding Trade

In 1913 the company extended its service to the welding trade, under a system generally similar to that relating to automobile lighting, but differing therefrom in the fact that its welding tanks are supplied to its customers under contracts which treat the tanks as held by the customer as containers merely of its gas, and on rental only, each tank bearing on the outer surface permanent legends, including the serial number of the cylinder, the date of manufacture, its weight and the fact that it is plaintiff's property, together with the statement that the acetylene is prepared and pressed into porous substance in compliance with certain governmental specifications, and that, when empty, it is to be redelivered to plaintiff.

Defendant Refilled Plaintiff's Tanks

The defendant, Auto Acetylene Co., is engaged in manufacturing and selling acetylene gas in tanks similar to those of plaintiff. Now the complainant alleged defendant's knowledge of plaintiff's rights, including its contracts and exchange service, and charged that defendant induced, procured and assisted plaintiff's customers in violating their contracts with plaintiff, by refilling tanks with defendant's gas, etc. An injunction was asked against such acts of defendant.

Defendant answered alleging that plaintiff's contracts with its customers amounted really to sales, that the consumers believed that they were purchasing the tanks and that such contracts violate the Clayton anti-trust act. Further, the defendant sought affirmative relief asking that plaintiff be enjoined from representing to

its customers that it is the owner of the tanks, and from seeking to prevent such consumers from having their tanks refilled by defendant.

Defendant Enjoined From Interfering

The final decree in the case enjoined the defendant from interfering with plaintiff's system of exchange and from causing such welding service contracts to be violated, and procuring the delivery of plaintiff's exhausted tanks to any one other than plaintiff for refilling or otherwise, from receiving or refilling such tanks or damaging the same, and from dealing in or exchanging such welding tanks.

Plaintiff Retained Title to Tanks

The court found that plaintiff by its contracts with customers retained title to the tanks, the contracts providing that complainant shall keep filled tanks in reserve and exchange them for empty tanks when returned without charge, except for the contents, and did not pass title in tanks. And the refilling by defendant of the tanks furnished by plaintiff to its customers for their use, but which remained its property, and in so doing knowingly assisted and encouraged customers to violate their contracts under which the tanks were furnished, was such a violation of plaintiff's rights as to entitle it to an injunction.

The important question presented was whether the contract between plaintiff and its customers violated the Clayton act, which makes it unlawful to lease "goods, wares, merchandise, machinery, supplies or other commodities" on the condition, agreement or understanding that the lessee shall not use the supplies of a competitor of the lessor, where the effect of such lease or condition, agreement or understanding may be "to substantially lessen competition or tend to create a monopoly."

If the transaction were an absolute sale of the tank (and the court found it was not), any restriction whatever upon its use would be void, independently of the Clayton act. The contract in substance forbids the customer to use in the tank any gas except that manufactured and packed by plaintiff.

Tanks Not Leased

Regarding the charged violation of the Clayton act two questions were presented to the court. One was whether the contract effects a lease of a tank, and the other was whether the refilling of the tanks with gas amounts to using or dealing in "supplies" within the meaning of the act. These were answered in the negative by the court. No given tank was leased, for under the contract any tank, of one class or the other, is in the first instance delivered to the customer. This tank is to be returned when empty. The same tank is not then returned to the customer, and may never be, but another tank of the same class is returned, refilled, and so on to the end of the service. The customer has no interest in any particular tank, except while filled and in his possession, and then only because it is the container of the gas.

It was found that the Mimeograph case, 32 Sup. Ct., 364, relating to supplies, did not apply here. The court says it is more proper to say that the delivery of the storage tank as a package or container is merely incidental to the furnishing of the gas than that the former is the subject of a lease and the latter a supply for a leased package. Acetylene gas cannot be bought, sold or delivered in the market in the way that ordina merchandise and "supplies" are sold and delivered; b it can be delivered only by filling the package with g compressed therein—a circumstance which differen ates it from supplies as the term is ordinarily used.

No Precedent to Guide Court

This case presents a new point and no precedent co be found to guide the court.

As to the charge that the contracts in question su stantially or unreasonably lessen competition or te to create a monopoly, it was shown there was no agr ment between competing companies, through division trade or regarding price, and the records showed highly active competition between plaintiff and defer ant, unless in the bare fact that the customer und contract with plaintiff is more apt, other things bei equal, to obtain its gas from plaintiff than from a co petitor. In this relation this case bears some analo said the court, to the so-called pump and tank cas where it was held that a requirement that deale distribute only the loaner's product from leased devic is not an unfair method of competition, nor does substantially lessen competition.

Belgian Artificial Silk Industry Approaching Pre-War Condition

The Belgian artificial silk industry, which before t war produced about one-quarter of the world's supp has recently shown unmistakable signs of improveme and the largest of the four mills in Belgium reports th present demand exceeds production. Production b fore the war averaged 2,700,000 kilos. Of the fo largest plants which survived the war, only one w able to resume manufacturing in July, 1919, but t other mills followed at short intervals, so that by t end of 1920 the industry had resumed about 70 p cent of its pre-war status.

Only 5 per cent of the total production was co sumed at home in 1914. Half of the total producti went to Germany, whence many of the raw materia and chemicals were obtained. In recent years, howeve exports of artificial-silk yarn have gone largely to t United Kingdom and Switzerland. The latter countr as may be seen from the following table, took 111,0 kilos out of a total export of 153,000 kilos exported Belgium in 1921:

BELGIAN IMPORTS AND EXPORTS OF WASTE-SILK YARN AN ARTIFICIAL-SILK YARN

	Imports			Exports		
			January-March,			Janu Mar
Countries	1920 Kilos	1921 Kilos	1922 Kilos	1920 Kilos	1921 Kilos	192 Kil
Germany	293	1,127	161	9,028	1,307	...
Spain	...	...	...	1,504	600	...
France	2,882	1,419	354	...	1,874	3,51
United Kingdom	1,441	1,133	252	7,856	29,451	6,03
Switzerland	1,357	1,047	153	5,278	111,463	9
Other	47	1	...	4,696	8,002	33
Total	6,020	4,727	920	28,362	152,697	9,98

Statistics concerning manufactures containing ar ficial silk can not be identified in trade figures. Sh ments to the United States, which for a time had fall off considerably, have of late been resumed, as so large American orders were placed with Belgian mi A brisk demand is also reported from Spain, Portug Switzerland and Japan, but despite the present activ one large manufacturer is pessimistic as to the futu of artificial silk manufacture in Belgium because tariff restrictions.

Effect of Temperature, Pressure and Structure on Mechanical Properties of Metal

Recrystallization, Annealing, Cold-Work and Inclusions Have Profound Effect on Size and Shape of Crystalline Grains and Therefore on Properties of Metal —A Study of the Mechanical Properties of Single Crystals

By Zay Jeffries and R. S. Archer

In a previous paper entitled "Mechanical Properties of Commercial Iron" (*Chem. & Met. Eng.*, vol. 27, p. 694, Oct. 4, 1922) the art of testing metals was discussed in a general way, and some indication given as to how the various circumstances surrounding the test —such as size of specimen or rate of loading—affect the results obtained. Given the fact that such extraneous conditions have been standardized and are under close control, three principal variables affect the properties of metal: temperature, pressure and structure. We shall have most to say on the third of these factors.

Temperature Scale

The recrystallization temperature constitutes a point of division in the temperature scale of a metal: at higher temperatures the metal is "hot" and at lower temperatures "cold." Deformation at 250 deg. C. is hot working for lead or zinc but cold working for iron or nickel. When the various ductile metals are compared at a fixed temperature, such as the ordinary atmospheric temperature, they are found to be widely different in mechanical properties, but if the comparison is made at temperatures similarly related to the respective recrystallization temperatures, the metals are found to be not so unlike.

Below the temperature of recrystallization the structure of a metal is relatively permanent. Any change produced by deformation prior to a mechanical test or by the deformation incident to the test itself is cumulative. Above the recrystallization temperature, on the contrary, the internal structure is constantly subject to grain growth which largely wipes out the effects of deformation. Material at grain boundaries also possesses a capacity for viscous flow under stress much greater than at lower temperatures. The phenomena encountered in the two temperature ranges therefore fall naturally into different classes.

There is another fairly marked but not very definite point in the temperature scale of a metal. It is the temperature at which the metal becomes brittle on cooling. Iron in the annealed condition is ductile at room temperature but brittle in liquid air (—185 deg. C.) unless very fine grained. Equiaxed tungsten wire is ductile at 200 deg. C. but brittle at room temperature. Annealed copper, however, is ductile at the lowest temperatures at which it has been tested. In general the temperature at which brittleness appears on cooling is highly dependent on the structure of the metal. This brittleness is often accompanied by low or erratic strength, due to the easy development of high local stresses by eccentric loading. It follows that values for strength are likely to be most dependable when the temperature of test is such that there is appreciable ductility.

The temperature scale of a solid metal can thus be roughly divided into three regions: (1) A region of low-temperature brittleness. For most metals this is below ordinary atmospheric temperatures. (2) An intermediate region above the temperature at which the metal becomes brittle due to cold, but below the temperature of recrystallization. It is in this temperature region that most metals are used. Mechanical working in this zone is called "cold-working" and causes an increase in hardness and decrease in plasticity. (3) A zone of hot-working, lying above the temperature of recrystallization. Metals possess little elasticity at these temperatures, but flow slowly under small loads. In this zone mechanical working can be carried on to a practically unlimited extent.

The strength and hardness of metals normally decrease on raising the temperature, while the plasticity increases. Fig. 1 shows the effect of temperature on the tensile strength, elongation and reduction of area of copper. The elongation was measured on a gage length equal to eighty times the diameter of the specimen, so the values represent general elongation practically unaffected by the local stretch at the fracture. The results obtained at the higher temperatures depend largely on the rate of loading. The tests from which these curves are plotted were made in from 2 to 10 minutes.

Tensile strength decreases continuously from —185 deg. C. to 950 deg. C., and is known to continue decreasing to the melting point (1,084 deg. C.).

Elongation also decreases continuously from —185 deg. C. to the melting point. Throughout the same temperature range the plasticity *increases*, but elongation depends on both plasticity and strength; the decrease in elongation with rising temperature is due to the large decrease in tensile strength. Since the elongation has its highest value at the lowest temperature shown, it is obvious that the entire curve lies within the last two of the temperature regions mentioned above—i.e., the intermediate and the high. Copper probably enters the low-temperature zone of brittleness some-

where between —185 deg. C. and absolute zero, but no actual tests are known to the authors.

Reduction of area increases slightly with rising temperature up to the temperature of recrystallization, above which it falls off sharply.

Tensile strength, elongation and reduction of area are all increased to a marked extent by increasing the rate of loading when testing above the recrystallization temperature.

Fig. 2 shows the effect of temperature on the elongation of annealed molydenum. In these curves the low and intermediate temperature zones are represented. Recrystallization occurs at about 900 deg. C., the highest temperature at which these tests were carried out. It is to be noted that the fine-grained wire retained its ductility at lower temperatures than the others.

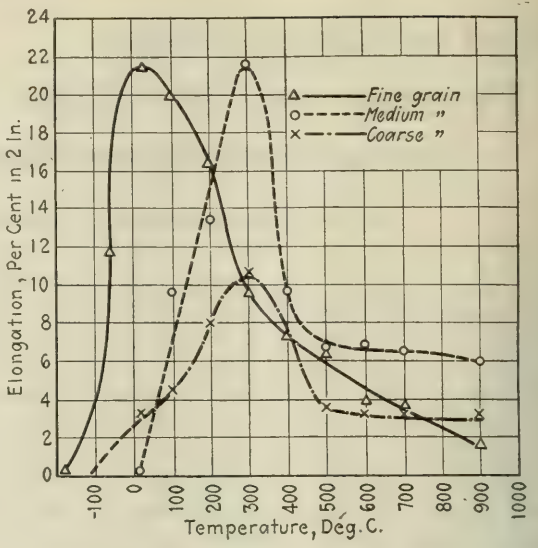

FIG. 2—EFFECT OF TEMPERATURE ON ELONGATION OF ANNEALED MOLYBDENUM WIRE (SYKES)

Pressure

Metals are perfectly elastic under pressure applied uniformly on all sides (under hydrostatic pressure). They are compressed as the pressure is applied, but on removal of the pressure regain their original volume except for the closing up of cavities. There is no permanent change in structure or properties. Hydrostatic pressure does not cause plastic deformation or cold-working effects.

Hardness increases with pressure, especially for soft materials. When a metal is under great hydrostatic pressure its resistance to deformation is greater than at low pressures.

Metals are seldom used under hydrostatic pressures of any important magnitude, but such pressures are encountered in some fabricating processes. Extrusion is probably the best example. The metal is confined in a receiver, usually of cylindrical form, and pressed out through a die by a ram. Pressure is exerted on the metal on all sides except at the opening through which it is extruded. When a metal is worked in confined dies, as in swaging, and to a less extent in pressing and forging, it is under hydrostatic pressure, although there are of course other forces which cause the desired deformations. Hydrostatic pressure acting on the metal in these fabricating processes contributes to its plasticity by holding the crystalline fragments in more intimate contact during deformation.

Elements of Structure

The crystalline grains of a metal may vary as to size, shape and orientation. Of these qualities size[1] is by far the most definite. Shapes are so irregular that they are not subject to more than qualitative description. The most apparent distinction is perhaps that between equiaxed grains and elongated grains. In this connection it must be remembered that the elongated "grains" of a cold-worked metal are in reality aggregates of very small grain fragments. In a strictly pure metal recrystallization ordinarily results in the formation of equiaxed grains. When sufficient insoluble (or soluble but segregated) impurities are present, there is a tendency for the grains to become longer in the direction of working. Elongated grains are also found in cast metal, especially after rapid solidification.

Grains also differ in shape with respect to their boundaries—whether made up of straight or of curved lines. Grain boundaries in ferrite (alpha iron), for example, are normally quite curved and irregular, although they tend to become more rectilinear after certain annealing treatments. In gamma iron and the austenitic solid solutions formed from it the grain boundaries are as a rule straight and regular.

To describe the structure of a metal with reference to the orientation of its grains is still more indefinite. To begin with, it is quite difficult or at least tedious to determine the orientation of any particular grain. It seems that ordinarily the grains possess fairly well-mixed orientations. X-ray diffraction patterns show, however, that in some cold-worked metals there is a tendency for the crystal fragments to assume a certain uniformity of orientation, which is found to persist to some extent after annealing. There is a peculiar type of "rectangular" brittleness sometimes encountered in annealed mild steel sheet which is attributed by Stead[2] to a more or less uniform orientation of the grains.

Fine grain is generally held to be a desirable structure, promoting toughness, strength and ductility. Strength and hardness increase as grain size decreases, at least in the intermediate temperature zone. At high temperatures fine grain is a source of softness, especially under prolonged application of load which leads to flow at the grain boundaries. In general, small grain size contributes to hardness under conditions of temperature and rate of loading which lead to deformation by slip.

Plasticity decreases with grain size, in the sense that more effort is required to bring about a given deformation and that the strain hardening effect of a given deformation increases. Malleability often increases as the grain size becomes smaller, however, because of the increased strength. Fine-grained zinc, for example, is malleable at ordinary temperatures, whereas coarse-grained zinc is brittle. Maximum ductility usually occurs at an intermediate grain size. Alpha brass, nickel, silver and copper show maximum elongation at room temperature after an anneal well above the lowest recrystallization temperature, but well below the melting point, and hence with medium grain size. The reduction of area seems to be greater

[1] Methods of measuring and expressing grain size are described in an article on Grain Growth, *Chem. & Met. Eng.*, Feb. 22, 1922, p. 343.

[2] "Brittleness Produced in Soft Steel by Annealing," J. E. Stead, *J. Iron & Steel Inst.*, 1898, No. 11. pp. 137-184.

the finer the grain, within the limits of our ability to produce fine-grained recrystallized structures. There must be a limit to the reduction in grain size beyond which further refinement of grain will produce less reduction of area.

Deformation

It is now known that cold deformation produces refinement of grain in the sense that one original grain, after severe cold-work, exhibits a mixture of orientations.[3] This type of grain refinement is not the same as the refinement of grain produced by annealing at low temperatures. For example, a metal may be obtained with the same hardness by moderately cold-working a coarse-grained piece or by annealing a severely worked piece at a temperature which will produce small unstrained grains. Although the hardnesses are the same, the other properties may not be and usually are not the same. These and other considerations make it necessary to consider that cold-working produces a structure unlike that obtained in any other manner. Even though there is refinement of grain by cold-working, the directional properties of the crystals are never obliterated, and in fact it seems that the extreme conditions of cold-work actually favor additional directional characteristics, such as a tendency for the crystal units to be oriented in a certain manner with reference to the direction of deformation. This condition has been described by Berger[4] in very fine tungsten wire.

Inasmuch as the structures produced by cold deformation are unique and are too minute for direct observation, the structural condition of cold-worked metals must be described in terms of the deformations to which they have been subjected.

The general effect of cold deformation is to increase hardness and decrease plasticity. The yield point and tensile strength are increased, and the elongation and reduction of area are decreased. The capacity for further cold-work is of course decreased. Annealing above the recrystallization temperature removes the hardening effects. Fig. 3 shows the effect of progressive cold-rolling on the properties of a very pure grade of copper. After being reduced cold 50 per cent in section, the metal was annealed at various temperatures, with the results shown on the right-hand side of the diagram.

[3] "Mixed Orientation Developed in Crystals of Ductile Metals by Plastic Deformations," by E. C. Bain and Zay Jeffries. *Chem. & Met. Eng.*, vol. 25, p. 775, Oct. 26, 1921.

[4] Communication from laboratories of N. V. Phillips Lamp Factory, Eindhoven, Holland, September, 1921.

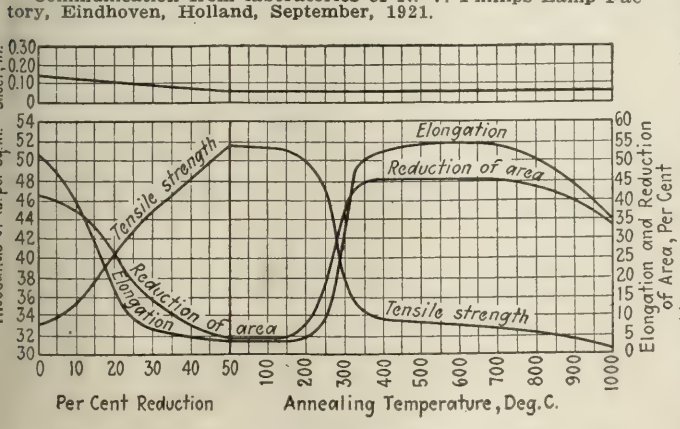

FIG. 3—EFFECT OF COLD-ROLLING AND ANNEALING ON PROPERTIES OF COPPER (MATHEWSON AND THALHEIMER)

In general the effects of hot-working are very much the same as those of cold-working followed by annealing above the recrystallization temperature. Although at high temperatures metals are capable of some permanent deformation by the process of viscous flow at the grain boundaries and perhaps migration of the boundaries themselves, most of the deformation incident to hot-working takes place by the breaking up of the crystals and the movement of the fragments along the slip planes. This type of deformation produces conditions favorable to grain growth. Immediately after a deforming operation, such as a hammer blow or a pass through rolls, grain growth takes place in accordance with the temperature until interrupted by the next deformation, which again breaks up the grains. The final grain size of hot-worked metal therefore depends largely upon the finishing temperature. A very high finishing temperature is apt to result in excessively coarse-grained metal. If, on the other hand, working is continued until the metal has cooled down around the recrystallization temperature, a somewhat strain-hardened condition may obtain.

Hot-working creates "fiber." Physical defects in a cast metal such as blow holes, pipes, slag or oxide films are drawn out in the direction of working. The non-metallic impurities, being often brittle at the working temperature, are also to a large extent broken up and scattered. The result is a general improvement because of the greater continuity of the metal, and a special improvement in the direction of the working. The distribution of the impurities is such that their total cross-section on planes perpendicular to the direction of working is much less than on planes parallel to the direction of working. This may lead to quite appreciably lower physical properties—particularly elongation and reduction of area—in test-bars taken at right angles to the direction of working, or "across the grain" of the metal. This effect is of course more marked the greater the amount of impurities present.

Impurities also affect the shapes of the grains. A perfectly pure and physically sound metal would, after hot-working, not only have the same properties in all directions, but would have equiaxed grains. Non-metallic impurities generally obstruct grain growth, and because of their distribution in worked metals, the obstruction to growth at right angles to the direction of working is greater than the obstruction to growth in the direction of working. The grains of hot-worked metals, or of metals that have been cold-worked and annealed, therefore tend to be elongated in the direction of working.

Properties of Metal Crystals

A single crystal is an aggregation of atoms occupying (or vibrating about) definite equilibrium positions to which they tend to return if displaced by the application of an external force. This gives rise to the property of elasticity. The mathematical exactness of the space lattice results in a perfection of elasticity not attained in non-crystalline bodies. It may follow that single crystals are perfectly elastic. Any deformation short of rupture produced by an external force disappears on removal of the force. Furthermore the extent of the deformation remains constant under a constant force—that is, there is no flow in a single crystal. The rate of application and the dura-

tion of load, therefore, are of little significance, and return to the initial form on removal of load takes place very quickly with none of that "creep" shown by amorphous solids.

Failure of crystals under load seems always to take place on crystallographic planes, which are to be recognized as planes of weakness. If the fragments adhere to each other, the crystal is said to be plastic, and the planes of failure are slip planes or gliding planes. If the fragments do not adhere, the crystal is brittle and the planes are called cleavage planes. In either case failure takes place by a shearing action, and the first failure marks the end of the single crystal. Up to this point the crystal is elastic. Therefore the only "strength-property" of a single crystal is its elastic limit in shear, which is of course different in different crystallographic directions. Hardness depends on the same property, since any method of hardness testing involves failure by shear. Conversely, we may regard the "strength" of single crystals, whether of pure metals or of metallic compounds, as approximately proportional to their hardness.

Crystallization of a metal from the molten state is accompanied by the sudden development of a definite shearing strength. This strength increases as the temperature falls in a manner which, so far as we know, is continuous, unless there is an allotropic change. The strength of a crystal is evidently due to the attractive forces between its atoms. Thermal vibrations of the atoms oppose these attractive forces so that at high temperatures the crystals are relatively soft and weak. As the temperature falls the amplitude of atomic vibration decreases and the interatomic forces become more and more assertive, increasing the hardness and strength. Since the damping of atomic vibration is a continuous function of the temperature, the increase in strength of a single crystal on cooling must also be continuous, as long as there is no change in the arrangement of the atoms—that is, no allotropic change. The modulus of elasticity also increases continuously on cooling.

The properties of crystals of the various metals depend on the characteristics of the atoms of which they are built and on the type of space lattice in which the atoms are arranged. Only three types of lattice, all simple, have been found in most metals. These are the face-centered cubic, body-centered cubic (or centered cubic), and hexagonal close-packed. All metals known to crystallize with the face-centered cubic arrangement are ductile throughout a wide range of temperature. Examples of this class are gold, silver, copper and aluminum. The hexagonal arrangement appears less conducive to ductility, as illustrated by the metals zinc, cadmium and magnesium. Hull has pointed out that in the hexagonal arrangement there is only one set of planes parallel to which easy gliding or slip can take place, whereas in the face-centered cubic there are four. Both ductile and brittle metals are found with the body-centered cubic arrangement, which seems somewhat less favorable to ductility than the face-centered.

Amorphous Metal

There must of necessity be some disorganization of the crystalline structure at the grain boundaries of metals and on most of the surfaces of slip. The degree of disorganization probably varies all the way from perfect crystallinity to the completely disorganized structure denoted by the term "vitreous amorphous." All such metal of disorganized structure simulates the vitreous amorphous materials in its mechanical properties.

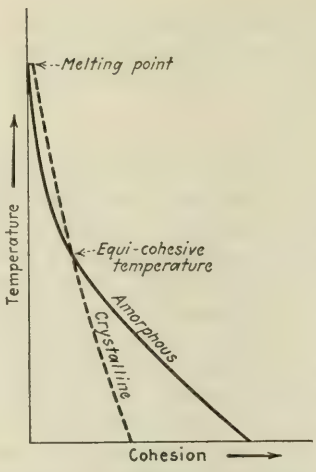

FIG. 4—COHESION-TEMPERATURE RELATIONS OF AMORPHOUS AND CRYSTALLINE METAL

Fluidity is the important characteristic of amorphous materials. Plastic deformation takes place by the same kind of flow as in ordinary liquids, except that at low temperatures the viscosity is very great. Whereas the strength of a crystal depends on temperature and is practically unaffected by the duration of loading, the resistance to deformation of an amorphous material not only varies rapidly with the temperature for a given rate or duration of loading, but if the temperature is constant depends entirely on the rate and duration of loading.

In Fig. 4 are two curves representing qualitatively the effect of temperature on the "cohesion" of crystalline and amorphous metal. For this purpose cohesion of crystalline metal denotes the stress required to cause failure by slip. That is, cohesion is measured by the elastic limit of the crystal. Cohesion of amorphous metal is also measured by the elastic limit—i.e., the maximum stress that can be sustained without permanent deformation. This quantity obviously depends on the time during which the stress acts. The curve therefore represents only one rate and duration of loading.

It will be noted that the crystalline metal is represented as acquiring a definite cohesion at the time of its formation—that is, at the freezing point of the metal—but there is no discontinuity in the cohesion of the amorphous metal at this point. Below the freezing point the cohesion of each modification increases continuously as the temperature falls, the rate of change being most rapid in the case of the amorphous metal. At some temperature the curves intersect, indicating that the cohesion of the amorphous modification has become equal to that of the crystalline. This temperature has been called the "equicohesive temperature." As indicated above, the actual temperature depends on the rate and duration of loading. In general it corresponds closely with the temperature of recrystallization. Above the equicohesive temperature the crystalline metal has the greater cohesion; below the equicohesive temperature the cohesion of the amorphous modification is the greater.

This conception is believed to be useful and suggestive in interpreting the properties of metals, but it must be remembered that it is qualitative rather than exact. It may be considered that in general the relative amount of amorphous metal increases with grain refinement and with cold-working. It may also be considered that in a qualitative way the greater the amount of the amorphous modification present the more do the properties of a metal tend toward those of a vitreous amorphous material. For example, the

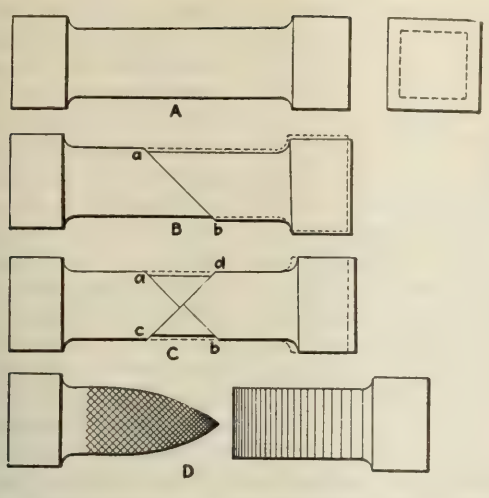

FIG. 5—PLASTIC DEFORMATION OF TEST-BAR COMPOSED OF SINGLE DUCTILE CRYSTAL

property which metals have at high temperatures of yielding slowly under constant load is presumably due (at least in part) to the viscous flow of the disorganized metal at the grain boundaries. Since the amount of this disorganized or amorphous metal is greater in a fine-grained metal than in a coarse-grained metal, we should expect the fine-grained metal to be softer at high temperatures and harder at low.

Tensile Tests of Single Crystals

Sykes[5] has described some very interesting tests of molybdenum wire in which many of the grains extended completely across the diameter of the wire (0.025 in.). At 200 deg. C. and lower temperatures the path of rupture followed the grain boundaries. At 300 deg. C. and up to 900, which is approximately the recrystallization temperature of molybdenum, the fracture was decidedly transcrystalline. In this temperature range, the wire drew down to a wedge at the fracture. The reduction of area was practically 100 per cent, but in one direction the *diameter* of the wire was scarcely reduced at all. This means that the deformation has been confined chiefly to two sets of slip planes.

The mechanism of deformation of a single crystal is illustrated schematically in Fig. 5, wherein *A* represents a test-bar of square cross-section consisting entirely of a single grain of a ductile metal. It is further supposed that this grain has such an orientation that planes of easy slip are perpendicular to the plane of the paper and make angles of about 45 deg. with the axis of the test-piece. Now if the piece is subjected to tension, shearing stresses are developed which reach a maximum value at 45 deg. to the tensile load and hence parallel to the planes of easy slip. As these stresses increase, failure of the crystal will take place in the form of slip, or block movement, along one of these planes, *ab*, the location of which will generally be determined by some local weakness. (Fig. 5-B.)

Ductile metals possess the property of automatically limiting the extent of the movement on any particular slip plane. Instead of slip continuing on the first plane until complete rupture of the piece occurs, the movement comes to a stop after a displacement which is very small as compared with the dimensions of the test-piece. Resistance to movement along the first slip plane increases; further slip is forced to take place on new planes.

Let us suppose that the second slip is on a conjugate plane *cd*, making an angle of about 90 deg. with the planes of the first set. (Fig. 5-C.) It is readily seen how repeated slips of this character result in a general increase in the length of the test-bar and a decrease in its diameter.

Fig. 5-D represents the test-bar after rupture. The view on the left shows the same surface of the bar as in the three views above, and illustrates the multiplication of intersecting slip planes, especially near the fracture. The view on the right shows a face of the test-bar at 90 deg. to that on the left. It will be noted that there has been no reduction in diameter on this face at the fracture. The test-piece has drawn out into the shape of a wedge.

A remarkable study of single crystals of aluminum has been reported by Carpenter and Elam.[6] These investigators worked with flat test specimens 1x0.125 in. and with round specimens having diameters of 0.564 and 0.798 in. With each type of specimen they succeeded in converting the entire parallel portion into a single crystal.

The bars of circular cross-section in which a single crystal occupied the entire cross-section drew out into the form of wedges, as did Sykes' wires. Because of the much larger size of the aluminum bars, the edge of the wedge was not actually sharp, but retained a well-defined lens shape at the fracture. Reduction in diameter in the other direction was very slight.

Flat single-grain test specimens of aluminum assumed forms during deformation and fracture which varied widely with the orientations of the grains, as would be expected. In one type the specimen became narrower, but retained practically its full thickness, while in a second type the specimen became thin, but retained substantially its original width. All bars were characterized by the small number of the systems of slip planes on which movement took place, and by a uniformity of direction of slip in any one grain.

Acetone as a Solvent for Mineral and Rosin Oils

In the course of an investigation being conducted at the Mellon Institute of Industrial Research of the University of Pittsburgh regarding the solvent properties of acetone on various commercial products, a number of mineral lubricating oils were tested. From the data thus obtained it has been concluded that acetone does not possess high solvent power for such oils. It was noted that the solvent power of acetone decreased as the viscosity of the mineral oils increased. Acetone is miscible in all proportions with gasoline and kerosene and possesses the least solvent action on the paraffin, from which it has been concluded that it is a better solvent for the lower molecular weight hydrocarbons.

Acetone has been used to remove paraffin wax from shale oil and lignite tar. Claim has also been made for its use in removing tarry matter from light lubricating oils, thus increasing their suitability for cylinder lubrication.

The grade of acetone used in these tests was obtained by the destructive distillation of calcium acetate and was of excellent purity and uniformity.

Deformation of Material by Impact Test

IT HAS BEEN frequently stated that anomalies in impact testing have been due to variations in the dimensions of the test-piece and to the habit of expressing the result in energy of rupture per square inch of fractured area. M. Moser of Krupp's laboratory recently tested[1] the theoretical conclusion that if the total energy of rupture were divided by the volume of deformed steel, the result would be independent of the size of the bar. His colleague, Dr. Fry, determined the volume of overstrained metal by the latter's new etching method.

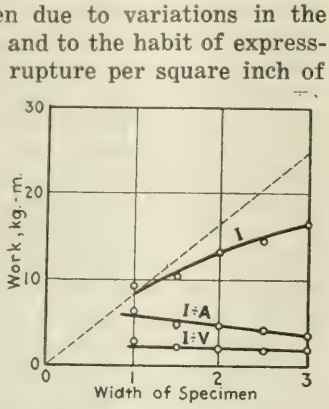

FIG. 1—IMPACT VALUES FOR 0.70 C STEEL

Standard German impact pieces are 3 cm. square notched by saw cut terminating in a drilled hole 4 mm. in diameter; the surface to be broken is 1.5 cm. deep and 3 cm. wide. Moser tested four steels (Table I) by varying the width of the specimen from 0.5 to 3 cm.

TABLE I—STEELS USED IN THE RESEARCH

	Analysis				Principal Properties			
	C	Si	Mn	Ni	Elastic Limit	Ultimate	Elongation	Contraction
Carbon steel A	0.70	0.24	0.52	....	57,000	112,000	12.2	18.0
Carbon steel B	0.43	0.16	0.36	....	43,000	71,500	30.5	51.0
Carbon steel C	0.35	0.29	0.61	....	49,800	78,300	30.3	56.4
Nickel steel D	0.12	0.05	0.35	4.85	60,200	73,900	32.5	70.8

His machine was of the Charpy type, its pendulum weighing 66.1 kg., falling 2.868 m. from an angle of 80 deg., and striking the piece with an energy of 189.6 kg.m. Results are shown graphically in Figs. 1 to 4 inclusive. Except for the nickel steel, the energy of rupture departs widely from proportionality. Likewise, that steel only has a constant value for energy of rupture per unit area. However, when the energy of rupture is divided by the volume of overstrained metal, the value is constant and independent of the width of specimen, yet quite different for the materials. Numerical results follow:

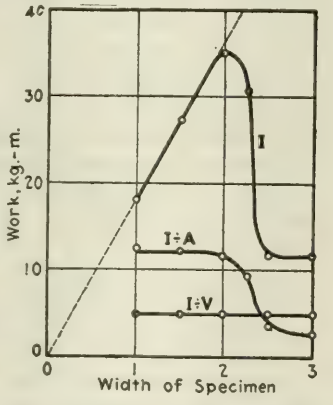

FIG. 2—IMPACT VALUES FOR 0.43 C STEEL

Steel	Rupture Work Per Unit Volume
0.70 Carbon steel A	1.9
0.43 Carbon steel B	4.8
0.35 Carbon steel C	5.3
4.85 Nickel steel D	11.6

As before noted, Dr. Fry examined the broken specimens by preparing polished cross-sections at various points and etching them by his newly developed methods. In this way the boundaries of the deformed material were determined and the volume of this material could be calculated.

A further striking relationship exists for the carbon steels between the contraction in area under tensile test and the rupture work per unit volume, as determined above, the latter being 0.094 times the former. This ratio does not apply to the nickel steel. Since the rupture work per unit of deformed volume is constant but the total work expended varies with the width of specimen, it follows that the volume of the steel overstrained must vary as the width of the specimen changes. Plotting such volume against width, we get four curves of the same shape as the respective curves for total work in Figs. 1 to 4. Each of the curves is tangent at its lower end to a line passing through the origin. The carbon steels deflect from this line when the width of specimen exceeds 2.0 cm., but the nickel steel holds to the line for widths as high as 3.0 cm. Strangely enough, the slope of the line is identical for all four steels. This seems to indicate that the amount of material deformed when breaking a test specimen notched according to the German standard depends only upon the width of the specimen. That is to say, the metal is deformed on the average 1.4 cm. deep on either side of the fracture, for specimens shaped as described and up to 2.0 cm. wide, despite the strength of the material. Figures for total work of rupture for such specimens should therefore give comparative figures; i.e., stand in the same relationship as the work per unit volume of overstrained metal[2].

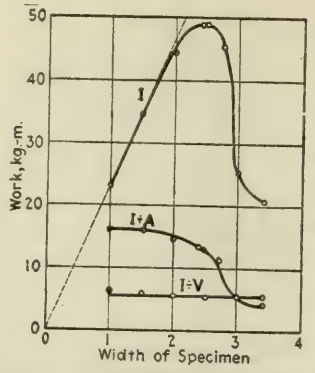

FIG. 3—IMPACT VALUES FOR 0.35 C STEEL

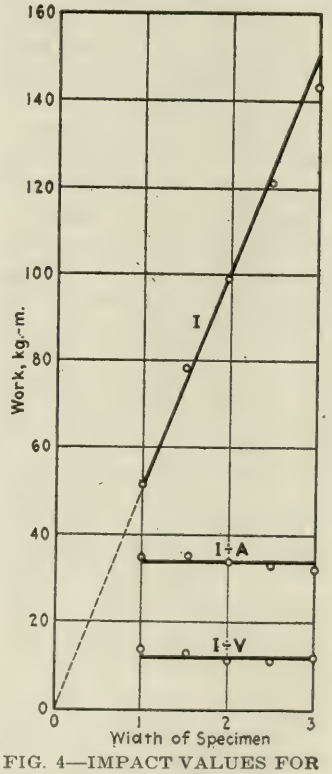

FIG. 4—IMPACT VALUES FOR 4.85 Ni STEEL

Since the energy of the falling hammer is far greater than that necessary to break the weaker steels, the height of fall was reduced to 1 m., just sufficient to break the 3.0-cm. test-piece of steel B. Testing pieces of different width with this milder impact, a series of curves similar in form to Fig. 4 were obtained, showing that under these circumstances the energy of rupture is now proportional throughout to the width of the specimen. The energy of rupture ex-

[1] *Stahl und Eisen*, 1922, vol. 42, p. 90.

[2] The following tabulation gives numerical results as determined from experiment, and from these an idea may be had on the correctness of the generalization.

VOLUME OF DEFORMED METAL

	Specimen 1.0 Cm. Wide	Specimen 1.5 Cm. Wide	Specimen 2.0 Cm. Wide
Steel A	4.0	5.5	6.8
Steel B	3.8	5.7	7.3
Steel C	4.2	6.5	8.3
Steel D	4.0	6.3	8.7
Approximation from rule	4.2	6.3	8.4

pressed in energy per unit of area or per unit of volume has become a straight line and a linear relationship exists between the deformed volume of metal and the width. The specimen is therefore behaving exactly as did the nickel steel with the higher velocity.

It is the purpose of notched-bar testing to localize the deformation at the root of the notch, the surrounding material being so strengthened and stiffened by its greater bulk not to enter into the test. Furthermore, it is apparent that the amount of material deformed by the shock depends upon the shape of the notch. The author, therefore, investigated the effect of the diameter of the hole ending the notch, using specimens of steel C, 2 cm. wide. Examination of the fractured pieces by Fry's reagent showed deformed metal to the following depth from the broken surfaces:

Diameter of Notch	Depth of Deformation
1 mm.	0.4 cm.
2 mm.	0.8 cm.
4 mm.	1.4 cm.
6 mm.	1.6 cm.
10 mm.	1.8 cm.
13 mm.	1.95 cm.

Practically there exists no method for the accurate and quick determination of the volume of material which is deformed by a blow. It would furthermore be very desirable to determine an impact velocity suited to the material to be tested so that it would fall by deforming the predicted volume of material. Neither of these ends being commercially obtainable, the best recourse is to devise a form of specimen in which the errors in question are minimized. For this purpose a specimen 1 cm. square in cross-section at the root of the notch and having the notch end in a hole 4 mm. in diameter is preferable.

Electrical Precipitation of Solids From Smelter Gases*

Suspended solids in smelter gases are largely sulphides, sulphates and oxides, but the physical condition is of far more importance than the chemical composition. Dust of any sort is easy to precipitate in a Cottrell treater; condensed fume is extremely difficult. The author thinks this is due to the fact that the fume first gathering on clean electrodes is compact, smooth, and a high insulator; on the other hand, the angularity of dust particles causes them to build up a granular deposit, the pores of which are lined with jagged points and rough edges from which an electric charge can readily leak. Both the gas and the precipitated coatings must be kept conductive.

It is of utmost importance, therefore, to condition fume-laden gas before treatment. In fact, it is an operating maxim to "get the gas right and electrical troubles may be forgotten." While fume precipitation may sometimes be increased slightly by introducing true dust, the best way now known is to add a certain amount of water vapor or sulphuric acid mist.

Water vapor may be put into the flue by spraying a considerable quantity of water finely atomized by very high air pressure. Since the relative humidity for good clearance and a dry deposit must be kept between 40 and 70 per cent, it follows that the temperature of the gases must be largely reduced in order to attain this with a reasonable amount of water. In fact, the evaporation of the water is of prime importance in reducing the gas temperature. Similarly, in winter it is often possible to cool the furnace gases by radiation so that their humidity will rise to the required limits. Mr. Rathbun believes that fume particles adsorb a surface film of water, which is held in the deposit without giving the appearance of moistness, yet having a great influence on its conductivity. Furthermore, humid gas is itself more conductive.

Conditioning with sulphuric acid is a more important method, since it permits good clearance on gas whose temperature (and therefore whose draft) has not been materially lowered. Sulphuric acid has a high enough boiling point so that it remains liquid at ordinary gas temperatures—it therefore aids conductivity because it actually wets the surfaces of the fume particles, spreading out at a very high rate. It also absorbs water vapor (and this water vapor must be supplied if the gas is naturally very dry) at temperatures well above 100 deg. C., so that the liquid films become dilute enough to be very good conductors of electricity. It is very necessary to add the acid at a high dispersion. This is effected best by boiling the acid and thoroughly mixing the mist with the gas to be treated—e.g., by spraying acid into the hot interior of a converter hood. If the solid particles react very rapidly, forming sulphates and thus wasting acid, conditioning must be done shortly before entering the treater, by an atomized spray of dilute acid. It has been found that good clearances are had in dust which contains from 1 to 5 per cent of free acid. Higher contents gives a sticky precipitate difficult to remove and handle. As high as two-thirds of the acid sprayed into the gas will pass through the treater.

Electrodes may be conditioned by slightly dampening them daily (or oftener if the fume contains much oxide) with fine H_2SO_4 mist. Acid appears to adhere to the collecting surfaces and absorb enough water from the passing gases to build up a continuous conducting coat.

*Abstracts of a paper read by Ross B. Rathbun, of the American Smelting & Refining Co., before the Vancouver convention of the American Institute of Electrical Engineers, Aug. 8, 1922.

Factice—A Rubber Substitute

A recent note published by the Stamford Rubber Supply Co. discusses the use of factice in rubber compounding. Factice is made from vegetable oils, ranging from the best imported French rapeseed oil to domestic corn oil. It is combined with sulphur chloride and the product thus formed, free from sulphur, from sulphur chloride and from the original oil, is called factice. It is a substitute for rubber and has often been called "rubber substitute." It has been found possible to use it in proofing cloth for clothing, hospital sheetings, carriage and automobile tops, etc. It is an economy to use it in this sort of work, as it cuts down the use of expensive solvents, such as gasoline, benzol, coal tar, etc., and permits a lighter, smoother spreading of the coating on the cloth. It is used in druggists' sundries, such as hot water bottles, and tubing, and numerous hard rubber articles. It is also used in tires to a limited extent, especially in the side wall, where from 5 to 10 per cent of the compound can be used. Bicycle tires can contain as high as 20 per cent of factice and even motorcycle tires use considerable amounts. And finally, it is used in mechanical work, such as belt frictions and covered stock or for conveyor belts, fire hose, etc. It has been in use in Europe for a long time among conservative and thoroughly reliable firms and it promises to have more extensive use in America in the near future.

Thermo-electricity

Since Seebeck conducted his original research, which covered a variety of phenomena, in 1821, a good many thermo-electric and electrothermic effects have been discovered and rediscovered over again. They are all interconnected; but three main effects may be distinguished, apart from the primary Joule effect—viz., that every conductor is heated by the electric current flowing through it. When the two metals of a heterogeneous circuit, consisting of two different metals in contact, are kept at different temperatures, an electric current is generated (Seebeck). When conversely an electric current is sent through that circuit, the junction is heated or cooled (Peltier, 1834). When the circuit is homogeneous and consists of one metal only, the temperature of which varies from point to point, however, an electric current is set up by the temperature difference (W. Thomson, 1856). The converse of the Seebeck effect, a generalized Thomson effect, had not been demonstrated, until Benedicks described his new X-effect. He claims to have established a direct "phoretic" transport of heat by the electric current, with or against the current direction, when flowing in a perfectly homogeneous conductor, of the same temperature throughout. The Thomson effect would only be a special case of this new effect. That heat transport would influence the Peltier and Thomson effects as usually measured; it would also play a part in the unipolar conduction of a crystal detector.

Investigation of Steel for Precision Gages

As an outcome of the organization of a committee of interested manufacturers and users (noted in *Chem. & Met. Eng.*, Feb. 8, 1922, p. 248), a 2-year program of research into the properties of gage steels has been agreed upon. Steels have been donated by the mills, the gages will be made by toolmakers, and the Ordnance Department, U. S. Army, and the Bureau of Standards have financed the experimental work. Howard Scott has been chosen investigator and will devote his entire time to the problem.

Six types of steel are to be investigated: carbon steels with 0.85 C, 1.10 C, and 1.10 C, 0.5 Cr; ball bearing steel with 1.10 C, 1.40 Cr; non-deforming steel with 0.90 C, 1.25 Mn, 0.5 Cr, 0.5 W; and a nickel-chromium case-hardening steel. It is planned to make fifteen thread gages and fifteen plug gages of each type, to study the influence of rate of heating before hardening.

A number of disks, 2⅛ in. diameter and 0.4 in. thick, are to be used to study the resistance to wear. While actual endurance in service is the ultimate test, a quick approximation is needed for an investigation, if for no other reason than to pick out steels worthy of service tests. Therefore the Amsler abrasion test machine is being studied. It produces dry wear on the periphery of two disks by a combination of rolling and sliding friction. Carbon steels are now being tested against oil-hardened steels in order to determine whether check runs give consistent results.

Changes in dimension on hardening are caused by at least two independent factors—viz., (*a*) temperature stresses due to non-uniform heating and cooling rates, and (*b*) volume changes due to the transformation of austenite to martensite. The former may be reduced by most careful control of the heat-treatment, a knowledge of the quenching power of the baths, or the use of an air-hardening steel. Given uniform cooling rates, the amount of distortion from austenite transformation should be uniform and predictable.

Slow changes in dimension on aging are probably due to a slow change in constitution of the steel; sudden changes to rearrangements of internal stresses. If these assumptions are true, the volume changes will be greatest and most rapid in untempered steel, and for investigative purposes it seems safe to assume that if a steel is stable as quenched, it will have better aging properties after tempering.

Machinability of a gage steel might best be studied by noting the temperature of the cutting tool when working under standard conditions.

These four tests—wear, changes upon hardening and subsequent thereto, and machinability—should permit one to determine readily the relative merits of a collection of commercial steels when used for gages.

A Steel Maker's Library

A number of leading men in the steel industry have been asked to select ten books on their specialty, which in their opinion would be most useful for inclusion in a business library to be installed in the Hotel McAlpin, New York. Replies were received from Charles M. Schwab, J. S. Unger, George G. Crawford, A. A. Corey, Jr., and John A. Mathews, citing the following books:

Title	Author	Publisher	Chosen By
Principles, Operations and Products of the Blast Furnace	J. E. Johnson, Jr.	McGraw-Hill	Co, Cr, S, U
Metallography and Heat-Treatment of Iron and Steel	Albert Sauveur	Sauveur & Boylston, Cambridge, Mass.	Co, Cr, S
Metallurgy of Iron and Steel	Bradley Stoughton	McGraw-Hill	Cr, M, S
Manufacture and Properties of Iron and Steel	H. H. Campbell	McGraw-Hill	Co, S, U
The Metallography of Steel and Cast Iron	H. M. Howe	McGraw-Hill	Co, Cr, M
Basic Open-Hearth Steel Process	Carl Dichmann	D. Van Nostrand Co.	Cr, S
Blast-Furnace Construction	J. E. Johnson, Jr.	McGraw-Hill	Cr, U

Recent Chemical & Metallurgical Patents

British Patents

For complete specifications of any British patent apply to the Superintendent, British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Magnesium Chloride — Anhydrous magnesium chloride is prepared by the action of chlorine on a mixture of magnesium oxide and carbon at a temperature below the melting point of magnesium chloride, the reaction materials being preferably dry and the carbon free from gas. The reaction is started at 300 deg. C. or above, whereafter a sufficiently high temperature is maintained by the heat of the reaction. Fusion or sintering of the chloride may be prevented by keeping the charge in motion—for example, by carrying out the reaction in a revolving converter. The temperature of the charge may also be controlled by feeding in fresh quantities of material and by adjusting the velocity of the chlorine current. (Br. Pat. 181,375; not yet accepted. Aktieselskabet de Norske Saltverker, Bergen, Norway. Aug. 10, 1922.)

Basic Magnesium Chloride — Basic magnesium carbonate is obtained by emulsifying the normal carbonate with water at 40 to 50 deg. C. in a homogenizing apparatus having at least one turbine bucket wheel. A product of the composition $4MgO{\cdot}3CO_2{\cdot}4H_2O$ is obtained. The normal carbonate may be obtained by mixing solutions of magnesium chloride and ammonium carbonate in an apparatus of the kind mentioned above, a product of the composition $MgCO_3{\cdot}3H_2O$ being thus obtained. (Br. Pat. 181,388; not yet accepted. Chemische Fabrik Griesheim-Elektron, Frankfort-on-Main. Aug. 10, 1922.)

Oxidation of Ammonia—The oxidation of ammonia by means of oxygen is effected by passing the gas mixture through a catalytic zone in which the concentration of the catalyst gradually increases in the direction of the gas flow; in this way mixtures containing up to 40 per cent of ammonia can be treated without explosion. The apparatus consists of a nickel or aluminum tube containing nickel rings, each of which carries a nickel net. Plates of platinized pumice are placed between the nets, the concentration of platinum increasing from the inlet to the outlet. The nickel nets and rings serve to conduct and radiate heat away from the reaction zone. (Br. Pat. 181,486. I. W. Cederberg, Lidingö-Brevik, and H. M. Bäckström, Djursholm, Sweden. Aug. 10, 1922.)

Purifying Acetylene—To basic materials such as a mixture containing ferric oxide and chloride, used for removing phosphoretted and sulphuretted hydrogen from acetylene, is added a copper compound such as copper hydrate or chloride to act as a catalyst. The mixture is incorporated with kieselguhr, and to it, in addition to the copper compound, may be added a small proportion of mercuric chloride. Improved results are obtained if the mixture is kept for some months before use; when exhausted it is revivified by exposure to the air. (Br. Pat. 181,571. J. R. Booer and District Chemical Co., London. Aug. 10, 1922.)

Synthetic Resins—Cyclohexanone or a homolog thereof is condensed with acetaldehyde, using an acid or alkaline condensing agent. The acetaldehyde in aqueous solution or otherwise is added gradually to a mixture of the cyclohexanone and condensing agent in a closed vessel and the whole stirred and heated. The product is cooled and stirred with water to remove soluble matter. Diluents or solvents may be employed. In an example, caustic soda acts as condensing agent and alcohol as diluent. The products may be employed as resin substitutes or in making varnishes, electric insulating compositions, etc. (Br. Pat. 181,575. H. Dreyfus, London. Aug. 10, 1922.)

Alumina — A solution of alum is treated with ammonia under such conditions that the alumina is precipitated in a readily filterable form. The alum solution is precipitated at a temperature near its point of ebullition, the ammonia is added gradually and the liquor is subjected to continuous agitation. An aqueous solution of ammonia may be introduced in the form of a spray into the alum solution, or preferably gaseous ammonia is injected, in order to utilize the heat of solution. After the removal of the alumina by filtration the potassium and ammonium sulphates are separated by crystallization, and the mother liquor is employed in the treatment of more alum. When the alum is obtained by hot lixiviation of crude material such as that obtained by treating leucite with sulphuric acid the precipitation may be effected advantageously directly while the solution is still hot. (Br. Pat. 181,678; not yet accepted. G. A. Blanc, Rome. Aug. 10, 1922.)

Imitation Metal Leaf—Thin films, particularly such as contain metal powder and serve as substitutes for metal leaf, are manufactured by applying a concentrated or pasty solution containing cellulose acetate, etc., and metal powder or pigment, by a single spreading operation on to a smooth support and then drying the film without further treatment. The support may be an endless band or a rotating drum or roller; and the solution may be supplied to a box in contact with the support and having an opening in its bottom, and spreading effected by a knife or a roller which may be stiff or flexible, for instance of india rubber. (Br. Pat. 181,706; not yet accepted. Akt.-Ges. für Anilin-Fabrikation, Berlin. Aug. 10, 1922.)

Ferrocyanides—Coal gas, preferably freed from ammonia, is passed through a mixture of a ferrous salt and an alkali such as sodium carbonate, preferably containing no free alkali, oxygen being excluded and the reaction being effected in the cold. The liquor is then treated with an oxidizing agent, such as air, to oxidize sulphides while leaving the ferrocyanide and any sulphocyanide that may have formed unaffected. The liquor is then filtered, the filtrate being alkali ferrocyanide solution. Prussian blue is obtained by acidulating this solution and adding a ferric salt or, preferably, a ferrous salt followed by oxidation of the precipitate with air. The precipitate first separated, consisting of ferric hydrate and sulphur, is treated with dilute sulphuric acid, preferably at 60 deg. C., when the sulphur collects in lumps and ferric sulphate is obtained which may be used to oxidize the ferrous ferrocyanide. (Br. Pat. 181,719; not yet accepted. A. Dessemond and A. H. Delcleve, St. Etienne, France. Aug. 10, 1922.)

Starch — Starch is obtained from wheat flour by the action of a single protolytic enzyme such as pepsin or trypsin which is without action on starch or its cellulose envelope, but which converts the insoluble nitrogenous constituents of the flour into soluble substances which can be removed by water. In an example a mixture of pepsin, water and hydrochloric acid is heated to 40 to 50 deg. C., the flour then being added and the heating continued till the density of the liquor remains constant. The amount of pepsin employed is 0.04 per cent of the weight of flour. When the reaction is complete the liquor is separated from the starch in a centrifuge, the starch being intermittingly washed with water till free from acid. If trypsin is employed, it is dissolved in a solution of sodium carbonate or bicarbonate. The starch is removed from the centrifuge and dried. Any gluten remaining in the starch may be removed by a solution of sodium hydroxide. The nitrogenous liquor obtained as a byproduct can be used as a fertilizer or as a base for foodstuffs. (Br. Pat. 182,829. F. H. Campbell, Melbourne. Sept. 6, 1922.)

Recovery of Sulphur—Sulphur in a pure state is recovered from an aqueous emulsion in which it occurs with gangue or other earthy matter by heating under pressure in an autoclave to a temperature above the melting point of sulphur but not exceeding 165 deg. C., the emulsion being agitated. Under these conditions the sulphur melts and may be separated by gravity from the aqueous liquid, the gangue, etc., remaining in suspension. The process may be applied to the mixture

of sulphur and flue dust obtained in the treatment of certain metallurgical gases. If, in addition to sulphur and gangue, metallic sulphides are present in the emulsion, they coalesce with the sulphur (which may be added if the amount originally present is insufficient) when the latter is melted as described above, the gangue remaining in suspension as before. (Br. Pat. 181,984. B. Hunt, London. Aug. 16, 1922.)

Dyeing Cellulose—Threads, filaments, strips or films of cellulose are dyed with vat or sulphuretted dyes by incorporating with viscose the leuco compound of the dye. The mixture or viscose and leuco coloring matter is preferably obtained by first bringing the dyestuff into solution and then mixing with the viscose, either as such or during its production. With a sulphur coloring matter sodium sulphide may be used in small quantities for this purpose, but it is preferred to replace it by sodium hydrosulphite. The use of large quantities of sodium sulphide is to be avoided. According to examples, Thional Black O.G., Duranthrene Blue C.C. and indigo are dissolved in caustic soda and sodium hydrosulphite and then mixed with cellulose xanthate. The mixture is spun in the usual way, and during the further treatment of the thread, particularly the washing and drying, the oxidation of the leuco compound proceeds. (Br. Pat. 181,902. Courtaulds, Ltd., London. Aug. 16, 1922.)

Dyeing Cellulose Acetate—Cellulose acetate goods are dyed direct in aqueous solution or suspension with non-sulphonated or monosulphonated soluble or insoluble dyes containing one or more of the following "active" groups: hydroxyl, amino, imino, imide, nitro, nitroso, isonitroso, acidylamino or azo groups; when a sulphonic group is present, the dye must contain at least two "active" groups. Carboxyl groups may be present or not. The dyes may be acid, basic or substantive dyes, vat dyes of the indigo or anthracene series, natural organic dyes, etc.

Salts which form double salts with basic dyes—for example, magnesium chloride, stannous chloride or zinc chloride—may be present in the dye bath when basic or other dyes are employed, or the basic dyes may be used in the form of such double salts. Examples are given of dyeing in an aqueous bath of gallocyamine DH, or in an aqueous foam bath of the kind described in specification 102,310 and containing insoluble Induline in suspension. (Br. Pat. 182,830. R. Clavel, Basel. Sept 6, 1922.)

Ammonium Sulphate — Commercial ammonium sulphate is neutralized by the addition of a solid neutralizing agent, preferably in powdered form, to the acid salt while it is being centrifuged. The neutralizing agent, which should be one capable of evolving a gas when in contact with the warm salt, is preferably added after the bulk of the mother liquor has been expelled, and is introduced into the centrifuge so that it becomes spread on the inner surface of the crystals in the lower portion of the basket. The flow of the remaining liquor then disseminates the neutralizing agent, or the gas envolved therefrom, throughout the mass. The salt is preferably discharged from the centrifuge before neutralization is complete, the continued decomposition of the reagent in contact with the hot salt serving to complete the process and, in addition, to dry the salt. The amount of neutralizing agent required may be less than the theoretical. (Br. Pat. 183,089. G. Weyman, Gateshead-on-Tyne. Sept. 6, 1922.)

Book Reviews

ELEMENTS OF INDUSTRIAL HEATING. By the engineers of the W. S. Rockwell Co., New York City.

"The influence of heat upon the quality and cost of practically all manufactured products, and the comparatively inefficient methods in general use, indicate the necessity of developing a broader view of the industrial heating problem. The demand for better and cheaper products can only be met with better methods of heating and handling, better equipment and, above all, men better qualified to understand and properly apply in practice the simple principles of one of the oldest and most important, though indifferently practiced, industrial arts."

There is no doubt of the importance of the problems thus outlined in the preface of this book, and furthermore there is no doubt that the engineers who have prepared it have done much for industry in furnishing this well-illustrated, effective summary of important considerations in fuel application. Much of the material in this book has appeared in pamphlets previously issued, but when this material is brought together under one cover, it again emphasizes the complexity as well as the importance of the fundamental problems as these problems are seldom stressed.

One of the purposes of this new book is to bring together in convenient form for the use of chemical and mechanical engineering teachers material that may be employed as a "supplementary textbook for shop training classes, vocational schools, colleges, etc., as well as for the man in the shop and others interested in the subject." Several institutions have already announced that they expect their engineering students to use this pamphlet. If this practice is extended widely, as it well may be, we may look forward to the time when engineers will think not alone of cost of fuel per ton or the relative cost of various fuels per million heat units, but rather of that important over-all efficiency, the fuel cost per unit of quality product. In bringing out the importance of that feature, this book gives attention not alone to the selection of the fuel but also to the selection of the furnace, the placing of the material in the furnace, the quality of product and the time factor in heating.

The book does not in any way argue for any single type of equipment or any particular fuel; it affords an unusually well-balanced and impartial review of the various types of heating furnaces, annealing equipment, automatic and continuous methods and the many variations of heat-applying devices that modern technology furnishes. It will be well worth while for experienced engineers as well as those beginning their studies in engineering to look through this booklet.

R. S. McBride.

THE LEAD STORAGE BATTERY. By *H. G. Brown.* 62 pp., illustrated. London, England: The Locomotive Publishing Co. Price, 5s. net.

As a handbook for those interested in the practical functioning of a storage battery, particularly stationary types, this book has considerable merit. It is exceptionally well written, being readable, clear and concise. The fundamental characteristics are given, but there is little attempt to discuss them and no attempt to include anything but very elementary theory.

The three opening chapters, which are largely introductory, deal with the chemistry of the lead cell, giving the familiar double sulphate theory. Characteristic voltage curves for charge and discharge are given and the influence of temperature is stated. A short chapter is devoted to a comparison of the Faure and Planté processes and characteristic structures and uses of each type of plate.

The main portion of the book, six chapters, is a discussion of stationary batteries, their construction, sphere of usefulness and maintenance. One chapter is devoted entirely to auxiliary apparatus such as boosters and automatic cut-outs. There are numerous wiring diagrams and the economies to be effected by the use of D. P. Battery Co., Ltd's., batteries are well advertised. All this material should prove of valuable assistance to the power plant engineer.

Unfortunately, however, the proportion of the industry interested in stationary batteries is much smaller in this country than in England. Only one chapter is devoted to our major product, portable batteries. This includes train lighting, vehicle, automobile starting and lighting and submarine, and, as far as it goes, is a good summary of the general demands in regard to voltage and capacity for each service and the types of batteries used. There are a few hints as to the care, but it is much too abbreviated to be of use to the American battery service station.

Since the book is so very well written both in regard to clearness of expression and the selection of essential facts, it is to be regretted that more emphasis has not been placed on the maintenance and repair of the portable type. Had this been included, the work would rank among the first of the storage battery handbooks. Helen Gillette Weir.

SYNTHETIC TANNINS: THEIR SYNTHESIS, INDUSTRIAL PRODUCTION AND APPLICATION. By *Georg Grasser*, Lecturer in Tanning Chemistry at the German Technical College, Brunn. Translated by F. G. A. Enna. viii + 143 pages. New York: D. Van Nostrand Co., 1922. Price, $4.

In the leather industry it has become customary to consider as tannins all materials which are capable of converting hide substance into imputrescible product. Without an understanding of this usage the term "synthetic tannins" is likely to appear misleading, since the chemical constitution of most of the industrial syntans bears not the slightest relation to that of true tannin. Indeed, much of the pioneer work on syntans was carried out before the chemical constitution of tannin was known. In order that this distinction may be clearly evident, the author devotes the first section to a review of the recent work on the synthesis of the true vegetable tannins. This is followed by a consideration of the different groups of syntans resulting from the condensation of phenols, hydroxybenzenes, naphthalene derivatives and products containing the anthracene, di- and tri-phenylmethane groups. The tanning effects of mixtures and of natural products other than true tannins (including sulphite waste liquor) are next treated, followed by a short section on analytical methods.

Part II covers the industrial production and application of syntans. Naturally, since much of the author's work was done in the laboratories of the Badische Anilin und Sodafabrik, the products of this company receive practically exclusive attention. Much of the material in this part will be of interest to the practical tanner, and the book should find a place in every tanner's library. ALAN G. WIKOFF.

A TEXTBOOK OF CHEMICAL ENGINEERING. Second edition. By *Edward Hart*, Ph.D. 241 pages, 229 illustrations. Easton, Pa.: Chemical Publishing Co., 1922. Price, $4.

Considerable additional information has been incorporated in the second edition of this book. New chapter headings include: Corrosion, Industrial Management, Pumps, Mechanical Handling of Materials, Autoclaves. Several of these could quite profitably receive more extended treatment in subsequent editions. It would seem that Professor Hart has formed the nucleus for a work which will become increasingly important as succeeding editions embody the suggestions which are sure to result from the author's earnest solicitations.

The author's perfect frankness on several points is quite refreshing. Thus, in speaking of obstacles to publication of information he says: "Boards of directors very often pursue the very silly policy of refusing to allow publication of information obtained in the working out of a process. The cry is that it has cost them much money and they are therefore unable to reveal it to competitors. This is true in some cases, but it is nevertheless true that the publication of many results whose publication could do no possible harm is forbidden in pursuance of a narrow policy which the directors deny in public and practice in private. As a result of this, research departments are often little better than information departments whose chief aim is to steal methods from competitors."

While many valuable data are scattered throughout the volume, the impression made upon the reader by the work as a whole is that of a collection of miscellaneous notes grouped somewhat hastily rather than a careful, orderly presentation of the subject. More attention to this point might add greatly to the value of subsequent editions without in any way interfering with the textbook style. Logical arrangement is not inconsistent even in a textbook. ALAN G. WIKOFF.

Synopsis of Recent Chemical & Metallurgical Literature

Comprehensive Study of Analyses of Coals

The results of analyses of hundreds of coals from 25 states and the Territory of Alaska are given in Bulletin 193, "Analyses of Mine and Car Samples of Coal Collected in the Fiscal Years 1916 to 1919," by Arno C. Fieldner, Walter A. Selvig and J. W. Paul, recently issued by the United States Bureau of Mines. Information as to the heating values of all coals tested is also given in the bulletin, which should be of interest to all extensive users of coal fuel.

Many mine samples of coal are analyzed each year in the laboratories of the Bureau of Mines. The analyses are made in connection with investigations relating to fuels belonging to or for the use of the United States Government, the causes of accidents in coal mines, the geologic relations of coal beds and the quality and the value of the coal and lignite in the public lands. The systematic collection and analysis of such samples in connection with fuel investigations were begun in 1904 at the government fuel-testing plant at the Louisiana Purchase Exposition, and were under the direction of the United States Geological Survey for 6 years. Descriptions of the coal samples collected between the beginning of this work, July 1, 1904, and the transfer of the fuel-testing and mine-accident investigations to the Bureau of Mines, July 1, 1910, were compiled and published in Bureau of Mines Bulletin 22. Descriptions and analyses of samples collected during the fiscal years 1911 to 1913 were published in Bureau of Mines Bulletin 85. Descriptions and analyses of samples collected during the fiscal years 1913 to 1916 were published in Bureau of Mines Bulletin 123.

In order that the material in this bulletin may be used to supplement that presented in Bulletins 22, 85 and 123, the same plan of geological classification has been followed, the analyses and descriptions of the samples being grouped in alphabetical order according to the states, county and town near which the mines or prospects sampled are situated.

Information regarding coal sampling and analytical methods employed by the Bureau of Mines and a bibliography on the coal resources of the world are contained in the bulletin.

The entire distribution of Bulletin 193 will be through the Superintendent of Documents, Government Printing Office, Washington, D. C., from whom the report may be obtained at a price of 35 cents. Bulletins 22, 85 and 123, the previously issued compilations of coal analyses made by the Bureau of Mines, are sold by the Superintendent of Documents at prices of 85, 45 and 50 cents, respectively.

Is Borax a Deleterious Constituent of Fertilizer?

Considerable interest during the past 5 years has been centered around the effect of borax in fertilizer on crops. This originated when the potash from Searles Lake was used in some mixed fertilizers and disastrous results followed. The reason for this was traced to the presence of borax in the fertilizer, and this in turn was traced to the Searles Lake potash. The recent paper of the United States Department of Agriculture, Bulletin 998 (July 3, 1922), by B. E. Brown of the Bureau of Plant Industry, is therefore extremely interesting. Experimental work was carried on during the year 1920 at various experimental fields of the Bureau of Plant Industry. Rows of potatoes were fertilized with a 4-8-4 mixture from nitrate of soda, sulphate of ammonia, cottonseed meal, muriate of potash and acid phosphate, the ammonia being derived equally from the three nitrogen sources. To this mixture was added 1, 2, 3, 4, 5, 10, 20, 30, 50, 100, 200 and 400 lb. respectively of borax per acre of ground. The yield from the various plots was compared. It is interesting that with 1, 2 or 3 lb. of borax per acre the plant growth is apparently stimulated, but when the borax is increased to 5 and 10 lb., marked injury and stunting of the plant is very evident. This effect is increased with 20, 30, 40 and 50 lb. of borax until with 100 and 200 lb. almost no plant growth is evident. From differences noted in the way in which the fertilizer is applied, it was found that if a week were permitted to elapse after the application of borax fertilizer, the effect of the borax was somewhat less, although not markedly so. This experimental work is a splendid contribution to the knowledge of the effect of borax on potatoes and is extremely interesting to the chemical industry in view of its connection with the Searles Lake potash. This potash, of course, has now been prepared free from borax so that no hesitation need be felt in its use. It served originally, however, to call attention to the borax problem.

Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Synthetic Chemical Interests Plan Tariff Change Appeal to Congress

Will Not Take Advantage of Appeal Under Flexibility Provisions of New Law Until After Attempt to Modify Rates in Congress

TARIFF duties on coal-tar products and synthetic organic chemicals from other than a coal-tar base will be the subject of attention when Congress reconvenes, although just what will be asked by the industries affected has not been made clear to the House Ways and Means Committee or the Senate Finance Committee.

From direct correspondence and other information received by the Finance Committee, it appears that at present there are three distinct movements in this connection to change the recently enacted tariff law and involving two, or more likely three, separate bills.

One of these movements looks toward a higher duty on synthetic organic chemicals and medicinals from other than a coal-tar base. The new tariff act gives these products a rate of 25 per cent ad valorem, foreign valuation. This was the rate recommended by the Finance Committee. The House used the same figure, but as the bill when it passed that body originally based ad valorem rates on American valuation, the result would have been much higher in cost of imports. The Bursum amendment, adopted by the Senate, placed these products on the same footing and with the same rates as coal-tar products, but after the various changes in conference the provision was stricken from the coal-tar paragraph and restored to an individual paragraph at the 25 per cent, foreign valuation duty. The duty on these products in the Underwood tariff varied, some being free and others bearing duty up to 20 per cent. However, for many months synthetic organic products were protected by the dye and chemical control act. This embargo was lifted with the effective date of the new tariff and the industry's protection dropped from an embargo to 25 per cent.

Will Appeal to Congress

Under the flexible tariff section, it would be possible for this industry to apply for relief through investigation by the Tariff Commission and Presidential proclamation increasing rates if the results of the investigation justified such action, but it is understood here that an effort first will be made to secure a higher rate direct from Congress. What rate will be asked has not been made known to the committees.

In connection with coal-tar products, two ideas have been suggested to the Finance Committee, which may be handled in a single bill or in separate measures, with the probabilities favoring the latter method if the ideas are to be pushed.

The first is to reclassify the paragraph on finished products entirely, and probably that on intermediates also, and to insert different duties for different products. The claim is advanced that some products do not require as high protection as given in the existing law, while others need much greater protection against foreign competition. The second suggestion is to remove the proviso in the Fordney-McCumber act which prohibits an increase in rates on coal-tar products under the flexible tariff section, these being the only rates to which this prohibition applies.

Overemphasized Dyes

Definite moves along these lines may be expected in a few weeks. Reception by Congress is of an uncertain nature. There is a strong bloc, especially in the Senate, which believes that the synthetic chemical industry has not been given adequate protection.

Friends of the industry believe that a mistake was made in the past in stressing dyes so strongly and that if at least equal emphasis had been put upon other features of the industry the results might have been different.

Would Expand Tariff Commission

The Director of the Budget has been asked to approve an appropriation of $1,000,000 for the United States Tariff Commission for the year 1923-24.

A study of the new responsibilities devolving upon the commission under the administrative sections of the Fordney-McCumber tariff bill are so great that the members of the commission think the present appropriation should be trebled.

If the directors of the budget and Congress approve the request for the $1,000,000 appropriation that the Tariff Commission has requested for the fiscal year 1924, a large expansion in the various commodity divisions will take place. The commission expects to enlarge its commodity division staffs all around, with the more pronounced increases in the sugar, chemicals and textiles staffs.

Franco-German Potash Combine Rumor Persists

Alsatian Company Admits Negotiations Relative to Division of U. S. Business

Reports persist that negotiations are under way looking to a division of the American potash market between Germany and France. French potash interests have repeatedly made the threat that they would enter into an agreement with the Germans if they did not secure a just share of the business in the American market. They advocate an allotment of 75 per cent of the American business to German producers and 25 per cent to France.

Inquiries made by the American Embassy at Paris at the request of the Departments of Commerce and State resulted in the following report to the latter department:

"The Embassy is informed by the Alsatian Commercial Co. that while conversations are being held relative to a potash agreement no decisions have yet been reached."

French Production Grows

Potash production in France increased during the second quarter of the current year, according to official French figures just furnished the Department of Commerce. The production during that quarter was 46,282 tons K_2O. The production during the first quarter was 38,733 tons.

A material increase is noted in the exports from France of the double sulphates of potash and magnesia. The exports of carbonated potash also have increased. On the other hand, there have been material decreases in exports of nitrate and chloride of potash.

The Sulphur Export Association

Taking advantage of the Webb law provision authorizing the organization of export associations, the three sulphur producers—namely, the Union Sulphur Co., the Freeport Sulphur Co. and the Texas Gulf Sulphur Co.—have entered into a combination for handling the sale of their product in foreign markets.

The new organization is to be known as the Sulphur Export Association and its officers are as follows: C. A. Snider, president; executive committee, H. D. Whitton of the Union Sulphur Co., E. P. Swenson of the Freeport Sulphur Co. and W. L. Aldridge of the Texas Gulf Sulphur Co. A board of directors, to consist of two representatives of each company, is still to be appointed.

Reparation Dye Plan Is Harmless to Industry

State Department Gives Assurance That American Dye Industry Will Not Be Jeopardized

No action toward the acceptance of reparation dyes to be credited against the United States' account for maintenance of American troops on the Rhine will be taken until Congress meets, the State Department has indicated, as legislation will be necessary to establish machinery for distribution.

Official word has come from the State Department that whatever is done in this matter will fully protect domestic interests and that the quantity of dyes to be accepted will be valued at only a small fraction of the American bill for troop maintenance. It was indicated that the value of the reparation dyes to be accepted under the contemplated scheme would be between $3,000,000 and $5,000,000 a year. In this connection it is pointed out that the life of the Reparations Commission, under the treaty of Versailles, has less than 3 years yet to run. It is said that the plan is acceptable to all of the Allies.

Outline of Proposal

Under the treaties, the Reparations Commission is entitled to 25 per cent of the output of the German chemical works. Of this quantity, approximately one-fifth has been allotted the United States. Until recently, when the act expired, the character of the dyes accepted here has been regulated by the dye and chemical control act. The Textile Alliance has been acting as unofficial distributor, and the money paid by the consumers has been sent to the Reparations Commission.

The general idea of the pending proposition is to accept approximately the same quantity and the same character of dyes and have the money paid for them go into the United States Treasury to be credited against the bill for keeping American troops in the occupied areas of Germany.

Machinery for Distribution

The machinery for the distribution of the dyes will be set up under executive authority, with Congressional sanction, it is stated. In advance of Congressional action, however, the State Department does not expect to reveal just how it will provide for the distribution. The Secretary of State declines to discuss how the prices of the dyes would be fixed or other details.

It has been intimated that probably authority will be asked to empower the President to dispose of this matter, which would enable him to designate any government department or any trade association for that purpose. A resolution to this effect was introduced in the Senate last July, but did not receive action before adjournment. However, assurance was given that the importation of the German dyes would not threaten with extinction the American dye or chemical industries.

There is no question about the deliveries of the dyes. This has already been arranged for, it was stated. The only question remaining now is how they are to be sold.

Congress heretofore has been wary of taking any action which might be interpreted as involving the United States with the League of Nations, but under the circumstances here presented, when a method for partly collecting a foreign account is held forth, a more favorable view might be taken.

Chemical Engineers to Survey College Courses

In accordance with the vote of the Institute of Chemical Engineers at the June meeting in Niagara Falls, the council of the Institute has appointed a committee on chemical engineering education. The purpose of this committee is to obtain, as far as possible, the adoption of recommendations, embodied in the final report of the former committee on this subject, by the educational institutions. It is intended that, after 3 years' efforts to obtain this adoption, the committee shall select and publish the names of institutions offering chemical engineering courses which are approved by the Institute.

H. C. Parmelee, editor of *Chemical & Metallurgical Engineering*, is chairman of the committee, which is composed of ten other members, five of whom represent educational institutions and five the industry. The members who are interested primarily in educational work are Joseph H. James, W. K. Lewis, A. H. White, R. H. McKee and S. W. Parr. The members engaged primarily in industrial work are C. E. K. Mees, A. D. Little, C. L. Reese, W. C. Geer and W. R. Whitney.

Hoskins to Address New York Section of French Chemical Society

"Experiences of a Consulting Chemist" is the promising title of an intimate talk which will be delivered by Dr. William Hoskins, of Chicago, before the regular meeting of the American Section of Société de Chimie Industrielle, at the Chemists' Club, New York City, Oct. 13, 1922. All chemists and chemical engineers of New York and vicinity are cordially invited to be present at this meeting, which should be extremely interesting, as Dr. Hoskins' experiences have been wide and varied, and his reminiscences will no doubt be entertaining as well as instructive.

Tables of Data Issued for Zinc Chloride Solutions

A copyrighted zinc chloride solution table has been issued by the Manufacturing Chemists' Association. The table shows the relationship between Baumé degrees, specific gravity, concentration, weight per cubic foot and pounds of zinc chloride per cubic foot. Approximate allowances for temperature also are shown.

Leading Paint Men Select Technical Books

Leaders in Industry Express Choices for Ten Basic Books in Field

The basic books in the paint industry, as selected by leading members of the industry for inclusion in the business library of the McAlpin Hotel of New York, have been announced by L. M. Boomer, manager of the hotel. These selections came to Mr. Boomer as a result of an inquiry instituted among the leaders in the paint industry to assist him in building up a business library of the ten books in each of twenty industries selected by the leaders of those industries.

Among those giving selections from which final choice will be made are:

Paul S. Kennedy, industrial department, Murphy Varnish Co., Newark, N. J.; G. B. Heckel, secretary Paint Manufacturers' Association of the United States, Philadelphia, Pa.; R. L. Hallett, National Lead Co. research laboratories, Brooklyn, N. Y.; Nathaniel D. Chapin, the Billings-Chapin Co., Cleveland, Ohio; Henry A. Gardner, Institute of Paint and Varnish Research, Washington, D. C.; J. Sibley Felton, president Felton, Sibley & Co., Philadelphia; Maximilian Toch, vice-president Toch Bros., New York City; C. M. Lemperly, the Sherwin Williams Co., Cleveland, Ohio; A. S. Butler, president McDougall Co., Inc., Buffalo, N. Y., and G. C. Morton, president Carpenter-Morton Co., Boston, Mass.

Among the books selected were:

The Manufacture of Varnish and Kindred Industries, Livache and McIntosh; Varnishes, Oil Crushing, etc., Livache and McIntosh;; Drying Oils, Boiled Oils, etc., Louis E. Andes; D. Van Nostrand & Co., New York City.

Technology of Paint and Varnish, Sabion, John Wiley & Sons.

Quality Varnish, P. S. Kennedy, Murphy Varnish Co.

White Lead—Its Use in Paint, A. H. Sabin, John Wiley & Sons.

Red Lead and How to Use It, A. H. Sabin, National Lead Co., 111 Broadway.

Lead and Zinc in the United States, W. R. Ingalls, Hill Publishing Co.

Linseed Oil and Other Seed Oils, W. D. Ennis, D. Van Nostrand & Co.

Lead and Zinc Pigments, C. D. Holley, John Wiley & Sons.

An Introduction to the Study of Physical Metallurgy, Walter Rosenhain, D. Van Nostrand & Co.

Metallurgy of Lead, H. O. Hofman, Scientific Publishing Co.

Metallurgy of Lead, H. F. Collins, Charles Griffin & Co., Ltd., London.

Painters' Colors, Oils and Varnishes, Hurst, Chas. Griffin & Co.

Chemistry of Paints, Toch, D. Van Nostrand & Co.

German and American Varnish Making, Bottler and Sabin, John Wiley & Sons.

White Paints and Painting Materials, Scott, *Modern Painter*, Chicago.

Mixed Paints, Color Pigments and Varnishes, Holley and Ladd, John Wiley & Sons.

Paint Technology and Tests, Gardner, McGraw-Hill Co.

Paint Researches and Their Practical Application, Papers on Paint and Varnish; Gardner, P. H. Butler, Washington, D. C.

Proceedings of Scientific Section, Paint Manufacturers' Association of United States, P. H. Butler, Washington.

Paint Researches and Their Practical Application; Paint Technology and Test; Papers on Paint and Varnish, H. A. Gardner.

Corrosion and Preservation of Iron and Steel, Garner and Cushman.

Mixed Paints, Color Pigments and Varnishes, Drs. Holley and Ladd.

Paint Vehicles, Japans and Varnishes; Lead and Zinc Pigments; Dr. Holley.

Pigments, Paint and Painting, E. Berry.

A.I.C.E. to Establish Student Chapters

Amendment to Constitution Provides for Undergraduate Societies in Engineering Schools

The Council of the American Institute of Chemical Engineers has reported that the amendment to the constitution, printed in full below, has been passed by letter ballot of active members. This amendment provides for the establishment of student chapters of the A.I.C.E. at engineering schools of high standing where there is an active member of the Institute on the faculty.

REGULATIONS FOR STUDENT CHAPTERS

1. A student chapter in affiliation with the American Institute of Chemical Engineers, composed of students in a school of engineering of recognized standing, whose teaching staff includes an active member of the Institute, may be organized upon favorable vote by the Council. The name of such an affiliated society shall be "The ————————Students Chapter of the American Institute of Chemical Engineers."

2. The qualifications required of a proposed student chapter shall include:

(*a*) An organization of students in an engineering school of high standing which affords opportunity for specialization in chemical engineering;

(*b*) The endorsement of the application by the head of the chemical engineering department;

(*c*) A minimum membership of 12 students.

3. Each student chapter shall establish its own rules of government and procedure, which shall conform with any regulations which may be formulated by the American Institute of Chemical Engineers. It is also intended that each student chapter shall control the occurrence and character of its own meetings; but the American Institute of Chemical Engineers desires especially to aid in promoting the success and value of student chapters by frequent consultations and advice, as well as by arranging for speakers, on request, whose address will broadly supplement the class-work of the members. To this end the Council of the Institute will elect a councillor for each student chapter from among the active members of the Institute, who shall advise the student chapter in its relation to the parent society, and who shall transmit with his recommendations the report of the chapter called for in section 4.

4. Each student chapter shall submit an annual report, not later than the last day of May of each year, which shall include:

(*a*) A summary statement of the meetings held during the calendar year; giving the date of each, the attendance, the principal speaker and his subject, and other pertinent information;

(*b*) Names of the officers, and number of members, by classes, at the date of the report.

5. The annual dues of each student chapter shall be $15 per year, subject to any regular assessment or increase of dues of active members of the Institute, which, under provisions approved by the Council, shall entitle it to the following:

(*a*) A copy of each issue of the *Bulletin* and *Transactions* of the American Institute of Chemical Engineers and of all papers and discussions printed as separates and programs of meetings;

(*b*) Attendance at meetings.

The annual dues shall apply to the current fiscal year and shall be payable in advance, due Jan. 1. The secretary of the American Institute of Chemical Engineers shall send out bills for dues each December for the following year. Student chapters admitted on or after July 1 of each year shall pay $7.50 only for the balance of the current fiscal year.

6. Among the privileges offered to the members of student chapters are:

(*a*) Individual subscription to the *Transactions* of the American Institute of Chemical Engineers at a special price of $4 per volume;

(*b*) To receive at cost, on request, copies of such separate papers as may be printed in pamphlet form;

(*c*) The right to attend the meetings of the American Institute of Chemical Engineers;

(*d*) The opportunity to hear, on special occasions, speakers whose personal experience qualify them to speak with authority upon the many questions which are of particular importance to the student during his college course.

7. Application for admission of student chapters to the American Institute of Chemical Engineers shall be in the form prescribed by the Council.

8. A student chapter may be disbanded upon its own request and with the approval of the Council, provided its annual dues for the current calendar year have been paid. The Council may discontinue a student chapter if its annual dues are not paid promptly, or if it becomes inactive, or if its continuance is considered not for the best interest of the Institute.

This step represents an attempt to supplement curriculum activities with advice and instruction which should be of value to the students in their professional work. Contact with the activities of the Institute should prove stimulating to the student groups.

Push Dam Construction at Muscle Shoals

Every effort is being made at Muscle Shoals to complete the excavation in cofferdam No. 2 and get the concrete in before high water. At present the work is being delayed somewhat by the difficulties of obtaining cement, sand and gravel. Progress would have been halted almost entirely had the Corps of Engineers not owned about 80 box cars. These box cars were handled in solid trains accompanied by convoys of Corps of Engineers men and used exclusively to bring in cement supplies. In this way it has been possible to avoid any serious slowing down of the cement work. Sand and gravel for this job come from a point down the river. Owing to the unusually low stage, great difficulty has been experienced in getting the floating equipment over the shoals.

COMPLETE IN 1925

As early next season as the water will permit it is planned to close the south channel and work actively in that cofferdam and in the powerhouse cofferdam. Unless unforeseen difficulties should arise, it is believed that the dam will have been completed early in 1925.

At the present time 1,100 men are at work at Muscle Shoals. To date there has been no difficulty in getting all the labor needed. The force, however, is to be expanded to about 2,000 and as the local labor supply already is under employment, some difficulty is expected in recruiting the additional labor which will be needed.

New York University Plans Courses in Ceramics

New York University has arranged to include the subject of clay products and clay products manufacture in a series of lectures on the geology of commerce and industry, soon to be started. The discussion will cover brick, tile and kindred products of the ceramic industry, dealing with the fundamental facts regarding the raw material situation, character and source of supply, methods and costs of preparing the raw materials for market, relation to other lines of industry, etc.

Iron and Steel Institute to Meet in New York

The twenty-second general meeting of the American Iron and Steel Institute will be held at the Hotel Commodore, New York City, on Friday, Oct. 27, 1922. A distinguished list of speakers have prepared papers to be read at the morning and afternoon sessions. Discussions from the floor will follow the reading of the paper. The complete program follows:

Address of the president, Elbert H. Gary, chairman, United States Steel Corporation, New York.

Modern Methods of Mining Coal, H. Foster Bain, director, Bureau of Mines, Washington, D. C.

The Storage of Bituminous Coal, H. H. Stoek, professor of mining engineering, University of Illinois, Urbana, Ill., and J. V. Freeman, director, coal and coke research laboratory, United States Steel Corporation, Joliet, Ill.

Present Status of the Electric Furnace in Refining Iron and Steel, J. A. Mathews, Crucible Steel Co. of America.

Economic Importance of the Power Plant in the Steel Industry, E. F. Entwisle, Bethlehem Steel Corporation, Steelton, Pa.

The Steel Requirements of the Automotive Industry, C. H. Wills, president, C. H. Wills & Co., Marysville, Mich.

Heating Furnaces for Blooms, Slabs and Billets, W. P. Chandler, Jr., fuel and experimental engineer, Carnegie Steel Co., Duquesne, Pa.

Use of Liquid Fuel in Metallurgical Furnaces, R. C. Helm, director, Worcester research laboratory of the American Steel & Wire Co., Worcester, Mass.

The Thermal Efficiency of the Open-Hearth Furnace, C. L. Kinney, Jr., superintendent No. 1 open-hearth department, South Chicago Works, Illinois Steel Co., South Chicago, Ill., and G. R. McDermott, fuel engineer, South Chicago Works, Illinois Steel Co., South Chicago, Ill.

Fluorspar and Its Uses, G. H. Jones, president, Hillside Fluorspar Mines, Chicago, Ill.

Chemical Experts Needed on Tariff Commission

The Tariff Commission under the new law has greatly increased responsibility with respect to many import matters. A considerable number of experts will be required to carry out this work, and, among others, several chemists will be needed. At an early date it is desired to add specialists on heavy chemicals and essential oils. Such men should, of course, be graduate chemists with some years of industrial experience and should be competent to prepare reports on domestic production, international movement of chemicals, competitive conditions, costs, etc.

Persons interested in such positions should take the matter up with the Tariff Commission, Washington, at once, as some of this work must be undertaken at an early date.

Some Impressions of European Chemical Industries

New York Section, A.C.S., Hears Interesting Talks by Parsons, Hendrick and Brooks—British Editor Also Speaks

The fall season of society activities in New York City was opened last Friday by an enthusiastic meeting of the local section of the American Chemical Society. A fair proportion of the section's 2,100 members were on hand to listen to the stories brought back by our recent European travelers —Parsons, Hendrick and Brooks—and to an engaging talk by our distinguished visitor, Frederick E. Hamer, editor *Chemical Age* (London).

Preceding the program scheduled for the evening, Dr. Charles L. Parsons, as secretary of the national society, was given an opportunity to tell of the plans now being made for educating the public to the vital importance of chemistry in our economic life. Two proposals have been made. The first is that each section of the A.C.S. should appoint a member whose duty shall be to interview every Congressman and Senator from the district and see to it that they have a proper appreciation of the relation of our science to the country's industrial and social progress. The second plan, reported to have been proposed by Mr. Garvan, was that the society should interest chemical and allied manufacturers to give the industry national publicity in all of their advertisements by including the sentence: *"This Is a Product of Our American Chemical Industry."*

Dr. Parsons Banquets and Dines

Later in the evening in describing his recent trip to Europe, Dr. Parsons gave a detailed account of the Lyons meeting of the International Union of Pure and Applied Chemistry, in which as a vice-president he represented the United States. His constantly recurring references to the many banquets, dinners and lavish entertainments at Lyons and later at Marseilles brought forth many a hungry and thirsty sigh from his audience. A more serious comment on these entertainments, however, was the fact that in contrast to some of our own scientific meetings, they were always attended by Cabinet members and other high officials of government and state.

From a technical viewpoint nitrogen fixation is still the most important subject of industrial research in Europe. In England the Dillingham plant is about to be put in operation to produce 100 tons of ammonia a day. The big problem at the Badische works in Germany, according to Dr. Parsons, is not in the fixation reaction itself but in the economic production of hydrogen. Because of difficulties and expense connected with the carbon-steam method, a great deal of study has been given to electrolytic hydrogen. This process is believed by them to be the coming method. Claude in France is said to have developed a process of taking hydrogen out of such gases as illuminating and coke-oven gas, by means of high pressures and low temperatures. Because of the quantitative recovery of such byproducts as benzol and ethylene it believed that the hydrogen can be obtained practically without cost.

British Chemical Industries

Mr. Hamer, who is in this country as a delegate to the meeting of the Associated Business Papers, Inc., declared that there is a growing feeling in England that the commercial and professional opinion of the industrial press offers better guidance to the government than does the manufactured politics of the daily papers.

Economic conditions in the British chemical industries have practically paralleled those in this country, according to Mr. Hamer's observations. Politically, however, he has reason to believe that they are better off in England than we are here. At least the government has definitely kept its promises to the chemical industries. The safeguarding of industries act, even with its shortcomings in administration and a strong opposition from the merchant class, has recently received a decidedly favorable vote of confidence by the British Parliament. Much of the credit for the general active condition of the British industry is due, Mr. Hamer believes, to the virile work of the Association of Chemical Manufacturers and its secretary, Mr. Woolcock; to the Chemical Engineering Group, the Chemical Industry Club, and various kindred organizations.

Personalities and Processes

Ellwood Hendrick's talk was mostly a bunch of anecdotes—interesting reminiscences of personalities and gossip about pleasant acquaintances made during his stay in London and his attendance at the meeting of the Society of Chemical Industry in Glasgow. He described the quaint customs, appearances and characteristics of some of England's foremost chemists, including such men as Sir J. J. Thomson, Sir William Pope, Professors Armstrong, Donnan and Ruttan, E. V. Evans and Stephen Miall. Finally, after threatening to exhaust his bountiful supply of superlatives, Dr. Hendrick described the interesting and business-like manner in which the Society of Chemical Industry conducted its annual meeting. There was the implication that some of our own societies could do well to emulate this excellent example.

Dr. B. T. Brooks closed the meeting with brief reference to a number of technological developments which had come to his attention while abroad. Most significant, perhaps, is the work in Germany on the hydrogenation of coal to produce liquid fuels resembling crude petroleum and yielding corresponding products on distillation. Over $5,000,000 has already been spent in developing this process, which by simple hydrogenation under high pressures is said to result in an 80 per cent conversion of bituminous coal to liquid and gaseous products.

Another interesting reaction is the British process of hydrogenating CO to methyl alcohol. With a yield attained of 80 per cent, methanol can be produced at a cost of 1s. per gallon.

Dr. Brooks also referred to the Anglo-Persion Co.'s new process for using hypochlorite solutions instead of sulphuric acid in petroleum refining. A paper on this subject which was presented by Dr. Brooks at Pittsburgh will shortly appear in *Chem. & Met.*

Literature Needed by Russian Engineers

The need of Russian scientists and technologists for American literature is well known. The division of engineering of the National Research Council is constantly receiving requests from various institutions in Russia for recent American scientific literature. It is urged that persons having extra copies of scientific books, periodicals, publications of government and state scientific bureaus and scientific institutions, and authors' reprints of an original character or containing technical information, which have appeared since 1914, contribute them for this worthy cause.

All shipments for scientists in Russia should be sent by express, or if very heavy, by freight, to the American Relief Administration, care of Gertzen Co., 70 West St., New York City. Each consignment forwarded to New York should be accompanied by a list of the publications sent. This will enable the New York office and the committee to check up the shipment and its receipt and distribution in Russia. One copy of this list should be placed on top of the literature before the package is closed and five copies, together with all letters containing advices of shipment, express and shipping receipts, should be addressed to the American Relief Administration, Russian Scientific Aid, 42 Broadway, New York City. The cost of overseas transportation of all material forwarded to New York is borne by the American Relief Administration. Its distribution in Russia will then be arranged for by the Russian Academy of Scientists or a special committee representing recognized Russian scientific organizations in cooperation with local units of the A.R.A.

Australian Investigations on Tanning Materials

For some time past the Institute of Science and Industry has been carrying out investigations on tanning materials in Western Australia. Two of the more important of these investigations have now been completed. One relates to the Western Australian red gum, Marri kino. A suitable process has been devised for getting rid of the objectionable red color which this kino imparts to leather when tanned with it. The other relates to a comprehensive investigation of the tanning materials of Western Australia.

Trade Commission Cites Turpentine and Celluloid Concerns

The Federal Trade Commission has issued a formal complaint against the Clifford Smith Co., of Richmond, Virginia, distributor of paints.

The respondent is charged in the complaint with exploiting, by advertising and by other means, a substitute for turpentine under the name of "Argentine turpentine," thus deceiving the purchasers of such commodity into the belief that the product is turpentine when such is not the case.

The Atlantic Comb Works, of New York City, has also been cited in a formal complaint by the Federal Trade Commission. The concern manufactures and sells toilet articles composed of nitrated cellulose or pyroxylin plastic, known commercially as "celluloid," "pyralin," "fibreloid," "viscoloid" and by other names. This product resembles ivory in color and general appearance and the respondent, the complaint alleges, exploits the same under the title and designation of "White Ivory," thus deceiving the purchasing public into the belief that the articles so distributed by respondents are made of ivory in whole or in part.

Stockholders Ratify Merger of Electric Alloy With Atlas

Stockholders of both the Electric Alloy Steel and the Atlas Crucible Steel, of Dunkirk, N. Y., have formally approved a merger into the Atlas Steel Corporation, organized under New York charter. The capital structure of the new concern is $2,000,000 bonds, $1,000,000 debentures, $2,000,000 of bank loans, $500,000 of prior preference stock, $6,000,000 of 7 per cent cumulative preferred stock, of which $5,000,000 will be issued, and 100,000 shares of no par value of common stock.

The company will have an annual productive capacity of 45,000 tons of high-speed and special-analysis steel, and will be the second largest independent producer in its field in this country. L. J. Campbell, chairman of the board and chief officer, says the Youngstown offices of Electric Alloy will be closed and quarters established at Dunkirk.

New Cement Plants to Be Built in Birmingham District

The announcement by the Lehigh Portland Cement Co. that it will immediately construct a portland cement plant in Birmingham, Ala., on a block of land next to the Alabama byproducts plant assures the construction of two large cement plants which will cost approximately $2,500,000 each. The estimated production of the Lehigh plant will be 1,000,000 bbl. per annum and that of the Phoenix recently announced 1,500,000 bbl. per annum.

The Lehigh plant will be built on 480 acres of land that is completely underlaid with limestone, thus giving an almost inexhaustible supply of one of raw materials.

Former Carnegie Steel Men Organize New Company

The Greenville Steel & Iron Co., recently organized at Greenville, Pa., has awarded a general contract to the McClintic-Marshall Co., Oliver Building, Pittsburgh, for the initial buildings for its proposed new plant on site lately acquired near the city limits, comprising about 35 acres of land. The structures will include an open-hearth furnace building, 100x150 ft.; 1-story rolling mill, wire-drawing mill, machine shop, warehouses, power house, and other mechanical buildings. At a later date it is proposed to construct a 500-ton blast furnace, additional rolling mills, foundry and other structures, to develop a maximum output of 350,000 tons of material per annum. Production will be devoted to steel castings, general steel products, wire specialties, etc. The entire plant is estimated to cost about $2,500,000, including machinery. H. P. Bope, formerly connected with the Carnegie Steel Co., is president; H. E. McConnell, consulting metallurgical engineer, also previously associated with the Carnegie Co., will be managing director. The Greenville Chamber of Commerce is interested in the project.

Manufacturing Chemists Appeal for Regular Car Supply

Irregular car supply has so interfered with the handling of certain of the heavy chemicals and chemical raw materials that it has been necessary for the Manufacturing Chemists' Association to make formal representations on the subject to the car service committee of the American Railroad Association.

Personal

RAY W. AMES, professor of mining engineering, University of Illinois, gave an address at a recent meeting of the Dallas Technical Club, at the Mecca Café, Dallas, Tex.

RAYMOND K. BOWDEN, of Niles, Ohio, has been appointed instructor in metallurgy for 1922-23, at Carnegie Institute of Technology, Pittsburgh. Mr. Bowden leaves a position with the Crucible Steel Co. in Pittsburgh.

C. A. BROWNE was nominated as chairman of the New York Section of the American Chemical Society at the meeting on Oct. 6. C. E. DAVIS was nominated for vice-chairman and B. T. BROOKS for secretary-treasurer.

ROBERT S. BRADLEY has been elected chairman of the board of the American Agricultural Chemical Co., New York. GEORGE B. BURTON has been elected president.

F. E. HAMER, editor of *Chemical Age*, London, is in New York as representative of Benn Bros., Ltd., to the meetings of the Associated Business Papers, Inc., and the National Conference of Business Paper Editors. Mr. Hamer intends to visit Philadelphia, Wilmington, Baltimore and other Eastern industrial centers before his return to England, which he plans for about Oct. 28.

H. W. HARDINGE is returning from a 3 months' trip in Europe, on the S.S. Berengaria, which sailed Oct. 3. His trip was for the purpose of studying mining and industrial conditions in Italy, Switzerland, France and England.

I. M. JACOBSON, who has been at the University of Chicago doing graduate work, has returned to the Bureau of Standards, where he will be engaged on the problems of aviation chemistry. The work will include particularly the studies of balloon fabrics and dopes for treating airplane fabrics.

FRANK M. JONES of the research department, Brown Company, Berlin, N. H., will leave Nov. 1 to accept the position of chief chemist of the Durex Chemical Corporation at Sweetwater, Tenn.

A. L. PITMAN, until recently assistant director of the Bangor station of the Massachusetts Institute of Technology School of Chemical Engineering Practice, is now in charge of the institute's consulting work for the Tidewater Oil Co.

JOHN F. PRICE has been appointed vice-president of the George T. Trundle, Jr., Engineering Co., 118 St. Clair Avenue, Cleveland, Ohio. Mr. Price was formerly comptroller of the Brown Hoisting Machinery Co., Cleveland, Ohio.

DAVID J. PRICE, engineer in charge of development work in the Bureau of Chemistry, has been designated by Secretary Wallace to represent the United States Department of Agriculture and co-operate with the Chamber of Commerce of the United States in the nation-wide fire-prevention movement now being undertaken by that organization. In this campaign considerable attention will be given to industrial dust explosions and fires, and Mr. Price will serve on the National Fire Waste Council.

W. S. RUGH, Montreal, Que., gave an interesting illustrated lecture on the smelting industry before the members of the local Rotary Club, at a recent meeting at the Windsor Hotel.

E. P. SAWHILL has been placed in charge of conveyor sales of the Brown Hoisting Machinery Co., of Cleveland.

Obituary

HERBERT C. FOLLINGER, manager of the Chicago office of the Chain Belt Co., died of pneumonia at his home in Chicago, on Sept. 27. Mr. Follinger was 38 years of age at the time of his death. He was born at Fort Wayne, Ind. He became associated with the Chain Belt Co. in 1914, and in 1916 was appointed district manager for the Chicago territory.

JAMES LUND, vice-president of the Merrimac Chemical Co., who had been with the company 38 years, died at his home in Malden, Friday, Sept. 29, 1922.

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

Present Trend of Coal Production and Prices

rogress Made Since Settlement of Coal Strike Indicates That a Possible Industrial Fuel Shortage Turns on the Question of Transportation Rather Than Mine Production

SLIGHTLY lower prices for soft coal and the widespread publicity iven to Henry Ford's advice that coal uyers "delay purchases, as prices must op further" have combined to bring out a situation in the coal market hich may entail grave responsibilities industry. In the opinion of the coal ade, as voiced by *Coal Age*, this can ean nothing but higher prices, "espe- ally with transportation conditions as ey are and will be this winter," and is on the question of distribution ther than production that the issue sts.

It is estimated that at present 25 r cent of the motive power of e railroads is out of commission, and is is at a time hen they are at- mpting to handle e peak of the ear's coal busi- ess. The general elief is that pres- nt delayed pur- hases will result a congestion fol- wing the resump- on of business on scale greater than an be cared for roperly by the arriers.

Production Leveling Off

roduction of both ituminous coal nd anthracite ap- ears to have eached a tem- orary level, bi- uminous at around 9,750,000 net tons nd anthracite at 1,850,000 tons a week. ccording to the reports of the Geologi- al Survey, "the total of all coal raised about 11,600,000 net tons, which is ill somewhat less than the amount re- uired to meet current consumption and e heavy movement up the Lakes, and t the same time to rebuild consumers' ocks."

Output of Anthracite and Bituminous

The output of anthracite during the eek ended Sept. 30 was estimated to e between 1,800,000 and 1,900,000 net tons, as against 1,856,000 tons in the preceding week.

The total production of bituminous coal, which is shown by weeks since 1919 in the accompanying chart, was estimated at from 9,600,000 to 9,900,000 tons. From these curves it will be observed that the present weekly rate of production is nearly a million tons above that of the year of depression, 1921, but is from one and one-half to three million tons below the years 1919 and 1920. Recent returns and figures for the cumulative production during 1922 for bituminous and anthracite coal and beehive coke will be found in Table I, prepared from data issued each week by the Geological Survey.

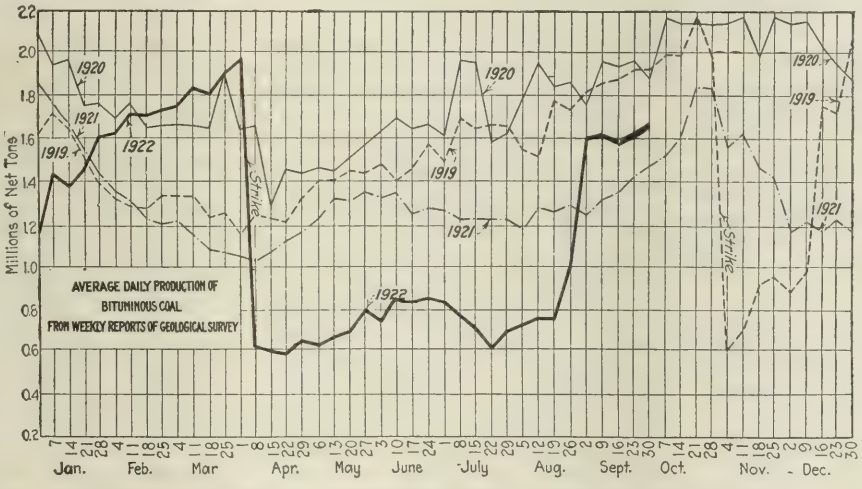

FIG. 1—ESTIMATED AVERAGE TOTAL DAILY PRODUCTION OF BITUMINOUS COAL

TABLE I—ESTIMATED PRODUCTION OF COAL AND COKE

(Net Tons)

Week ended:	1921	1922
Bituminous Coal		
Sept. 9 (*b*)	7,083,000	8,791,000
Sept. 16 (*b*)	8,187,000	9,737,000
Sept. 23 (*a*)	8,527,000	9,702,000
Daily average	1,421,000	1,617,000
Calendar year	286,550,000	261,149,000
Daily average, cal. year	1,280,000	1,162,000
Anthracite Coal		
Sept. 9	1,483,000	50,000
Sept. 16 (*b*)	1,749,000	1,107,000
Sept. 23 (*a*)	1,725,000	1,856,000
Calendar year	67,759,000	25,224,000
Beehive Coke		
Sept. 16 (*b*)	64,000	123,000
Sept. 23 (*a*)	70,000	135,000
Calendar year	4,034,000	4,625,000

(*a*) Subject to revision. (*b*) Revised from last report.

Beehive Coke Production

Late returns for the week ended Sept. 16 reduced the estimates of beehive coke production in that week to 123,000 tons. Reports for the following week (Sept. 18-23) indicated an out-turn of 135,000 tons. This was nearly double the out-turn of the corresponding week in 1921, but was only one-third of the average weekly rate in 1920. Reports more recently received from the principal coke carriers indicate that during the last week of September the output jumped to 162,000 net tons, an increase over the preceding week of 18 per cent.

Cumulative production during 1922 stands at 4,625,000 tons. In the corresponding periods during the 4 years immediately preceding it was as follows:

1918	22,489,000	1920	15,695,000
1919	14,485,000	1921	4,034,000

Thus 1922 is 79 per cent behind 1918, 68 behind 1919, 71 behind 1920, and but 14 per cent ahead of 1921.

Coal Prices

The *Coal Age* index of spot bituminous prices declined on Oct. 5 to 404, as compared with 418 for the preceding week. This corresponds to an average spot price of $4.89 at the mines.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	150.78
Last week	150.14
October, 1921	151
October, 1920	263
April, 1918 (high)	286
April, 1921 (low)	140

Practically all of the gains reported last week were maintained and there were a few additional advances. Citric acid, borax and cottonseed oil quotations were somewhat higher and more than compensated for the slightly lower prices of caustic soda and linseed oil.

The General Rise of Commodity Prices

Wholesale prices, as measured by most of the general commodity indexes, have shown a distinct rising tendency except perhaps for August and September. The Bureau of Labor Statistics figure based on 404 commodities—including both raw materials and finished products—stood at 150 for June, increased to 155 for July and continued without change in August. The trends of the various groups are shown in Table II.

TABLE II—INDEX NUMBERS OF WHOLESALE PRICES, BY GROUPS OF COMMODITIES
(1913=100)

	June	July	Aug.
Farm products	131	135	131
Foods	140	142	138
Cloths and clothing	179	180	181
Fuel and lighting	225	254	271
Metals and metal products	120	121	126
Building materials	167	170	172
Chemicals and drugs	122	121	122
House-furnishing goods	176	173	173
Miscellaneous	114	114	115
All commodities	150	155	155

The twenty-five representative chemicals included in *Chemical & Metallurgical Engineering's* weighted index of chemical prices have declined for the most part during the past few months. There is reason to believe, however, that September's average of 147.70 marks the low point in the present movement and barring unfavorable developments at present unforeseen, a gradual and consistent improvement may logically be expected during the fall and winter months.

More Cement Made and Shipped in August Than in July

Cement production in the United States during August, according to the Geological Survey, totaled 11,864,000 bbl., an increase of 107,000 bbl. over the preceding month. Shipments amounted to 14,361,000 bbl., or 511,000 bbl. heavier than July.

PRODUCTION, STOCKS AND SHIPMENTS OF PORTLAND CEMENT, BY MONTHS, 1921-1922

Despite the fuel and car shortage, both production and shipments during August show improvement over July records. In fact, the August output exceeds that of the corresponding period in 1921 by 1,420,000 bbl. Shipments in August, 1922, showed an increase of 2,021,000 bbl. over the same month last year. A rate of shipment in excess of production left only 5,737,000 bbl. in reserve at the end of August, which was 2,696,000 bbl. under the stocks on hand July 31.

The Iron and Steel Market

PITTSBURGH, Oct. 6, 1922.

The recent curtailment in pig iron and steel production proves to have been no more than an episode. The rate of production in June had been the highest of the year and that rate is now practically regained. The deficiency in production in the three intervening months, from production that would have occurred with the June rate, is less than half a month's output at the June or the current rate. Undoubtedly a material part of the steel shipped up to Aug. 1 had been ordered as a safeguard against the coal strike interfering with steel production and the provision may easily have been ample to cover the slight restriction that occurred. Of late steel buyers have been menaced with transportation restriction. Now the restriction is a fact and there is danger of there being somewhat greater restriction.

TRANSPORTATION DIFFICULTIES

Car shortages, for shipping finished product, are experienced at most steel plants, and in some cases the shortages are very severe. The noteworthy item is that the Carnegie Steel Co. has piled 100,000 tons of finished and semi-finished steel, all of which should have been shipped as made. The American Sheet & Tin Plate Co. is motor trucking sheet bars from Duquesne to McKeesport and Monessen, and even at that has had approximately a 10 per cent reduction in its finishing mill operations, from lack of steel. Box cars have been scarce for many weeks, but by dint of effort the company has been able to ship nearly all its product.

Open-top cars are now even scarcer than box cars, this being attributed to the coal movement. While much is being said, the exact situation cannot be appraised. There is no ready explanation of the fact that cars are so scarce when it is seen that the total car loadings in the week ended Sept. 16 were only 6 per cent under the record week, for if one attempt to explain by reference to there being a heavy coal movement he is confronted by the Geological Survey's report that bituminous coal production in that week was less than 10,000,000 tons, whereas in many weeks in 1920 there was production of more than 12,000,000 tons. The fact simply remains that there is loud complaint that steel mills do not obtain enough cars to load all their product, while hitherto the complaint has been that not enough coal and coke was being received.

Advances in basis prices of finished steel products, for late delivery, appear to have ended. At the same time delivery premiums are tending to diminish. The prospect seems to be that within a few weeks all delivery premiums will have vanished. Later, it is likely that basis prices may decline somewhat. The swing is more easily predicted than the time. The general buying movement ended recently, present activity being in early deliveries only. Another general buying movement will scarcely come until after there has been a period of quietness, during which some declines in basis prices can barely be avoided. The chief question is as to the extent of the prospective declines. The low point of early this year cannot be attained, as wage rates are much higher. Furthermore, it is impossible that sellers will again quote below cost, as it was claimed they did early this year. The experience then does not encourage a repetition now.

Events confirm the wisdom of the rail mills in their recent offer to book rails for the first half of 1923 at the old price of $40, in anticipation of the advance to $43, effective at the beginning of this week. Exact figures are not obtainable, but it appears that rails ordered will total considerably more than a million tons, while there has also been heavy buying of joints, bolts, spikes and tie plates, making a total business put under cover of about one and a half million tons. When the offer was first made it was not clear in all quarters that the mills would have spare production in the winter, but it is now plain that the orders will be needed in winter and probably in spring.

STEEL AND IRON PRICES

Bars and shapes are 2@2.25c. in the open market, depending on delivery and character of order, plates being 2.15@2.50c., but with little tonnage at above 2.25c. The Steel Corporation price seems to be 2c. on all three products, but buyers are no longer interested in such deliveries as the corporation can make, its order books being very well filled. The 3.35c. sheet price of the corporation is nominal, as the corporation is sold out until it opens books for first quarter. Independents are getting 3.50@3.60c., according to tonnage and delivery. Nails are uniform at $2.70. Pipe prices are practically uniform, on a 68 per cent basing discount, and all mills are far behindhand in deliveries of merchant pipe, particularly butt weld galvanized. Tin plate demand is seasonally poor, with $4.75 remaining the regular market.

Valley merchant furnaces have scarcely any pig iron to offer. For Pittsburgh delivery the market seems to be in control of the Cambria Steel Co., which is quoting $33 on bessemer, $31 on basic and $32.50 on foundry, f.o.b. Johnstown, with $1.77 freight to Pittsburgh, the same as from the valleys.

Connellsville furnace coke is up 50c., at $12@$12.50, and foundry, still quotable at $13.50@$14, is stronger at that range. Offerings in the open market are very limited, although production on the whole continues to increase. The limiting factor is car supply, rather than the strike, this having been the case for about a month.

The Pittsburgh district coal market is lower, good grades of steam coal being available at $3.50@$3.75, or about 50c. less than a week ago. Gas coal is off about 25c. Byproduct coal is barely quotable and cannot be said to be easier.

The St. Louis Market

ST. LOUIS, MO., Oct. 5, 1922.

Trading in the industrial chemical market has been along very active lines during the past two weeks, and from present indications should continue at this pace. Some of the heavy chemicals which have only been marking time for the past few months have now shown a remarkable improvement. This is particularly true of such items as phenol and some of the potash salts. Prices have been on the upward trend since the new tariff became effective, but are gradually firming up, and it is hoped that in a very short time the market will again be stable.

ALKALIS

Nothing beyond the ordinary has happened in the alkali market since our last report. Only a routine business is being transacted, but prices are firm at former levels. *Solid caustic soda* in 5- to 10-drum lots is still being quoted at $3.90 per 100 lb. delivered buyer's door, with the usual differential prevailing for the flake. *Soda ash* is moving only through the normal channels, with prices the same as previously reported. In 5- to 10-bag lots $2.20 per 100 lb. for the regular 58 per cent light is being quoted. *Bicarbonate of soda* has advanced slightly and is now being quoted at $2.50 in 5-bbl. lots. In some instances this is being shaded slightly, but such is the exception and not the rule. *Sal soda* business is only routine, with prices a little weaker if anything.

GENERAL AND SPECIAL CHEMICALS

Heavy mineral acids are going very well, with a noticeable increase in the demand during the past month. Prices on all grades have been very strong with the exception of *muriatic*, which has been sluggish. Manufacturers report, however, that the former large stocks of this acid are now about depleted and that a firmer market will again be established. *Phenol* has been moving in large volume in spite of the sharp increase in price, and further advances would not prove surprising. Trading in *citric acid* since our last report has been quiet, but sales are still being restricted by manufacturers, which would indicate that spot stocks of domestic goods are very small. Prices are firm. Spot goods of *oxalic acid* are still difficult to locate and are being quoted at 17½@18c., St. Louis. The demand has been exceedingly active. *Ammonia water* continues to move in a routine way, prices remaining the same. *White arsenic, powdered,* is ruling at 9c. per lb. f.o.b. New York in carload lots, with a very strong market and a scarcity of supplies. The demand for *carbon bisulphide* has been along steady lines and prices very firm, which is explained by the fact that supplies have not been heavy and no surplus stocks accumulated this season. There has been very little change in the *copperas* situation—that is, so far as supplies are concerned—but since our last report producers have advanced their prices $2 per ton and now quote $20@$21 per ton in bulk, f.o.b. factory. *Glycerine* is going strong and the market is safely in the hands of producers. Our prediction of two weeks ago has been more than fulfilled and prices of 18½c. in drums are being firmly maintained. *Sulphur* has eased up a bit in price and is now being quoted at $1.90 in 50-bag lots. There is no natural cause for this decline in price, since the demand is at least normal. Price cutting among producers is probably the explanation. The market for *zinc dust* is very quiet with no change in prices, which are now being quoted at 9½c. in carload lots, St. Louis. The *zinc sulphate* market is very strong at 3½c. in carload lots, f.o.b. St. Louis. It would not be a surprise to see an advance very shortly.

VEGETABLE OILS AND NAVAL STORES

Castor oil has shown no inclination to weaken and the best that can be done now is 14c. per lb. in drums for U.S.P. No. 1. This item is moving strong with a good demand and producers are in control of the market. *Turpentine* has wavered very little since our last report and is now quoted at $1.41 per gal., as against $1.40 when we last reported. *Linseed oil* has done little in the way of price changing and users are limiting purchases to immediate demands.

The New York Market

NEW YORK, Oct. 8, 1922.

Many of the chemicals imported in largest quantity have continued in the advance noted last week in these columns. Although transactions in the aggregate have not been materially greater than during the past few weeks, the general tone of the market has improved considerably. The industry, on the whole, is quite optimistic concerning future business.

An interesting comparison can be made with the market one year ago and at present. Then buyers were quite cautious on surplus material due to the downward tendency of prices and purchases were mostly of a hand-to-mouth nature. The capital issue in the present market is not how low prices are going, but to what extent the upward trend will continue. Yellow prussiate of potash was offered during the latter part of 1922 at 24c. per lb. Present quotations range around 38c. Citric acid sold at 42c. during January and is bringing 52c. per lb. on the spot market. Barium chloride was offered quite freely at $50 per ton in 1922. The present market is exceedingly strong at $105 per ton. The same sort of comparison also holds for acetic acid, acetate of lime, formaldehyde, oxalic acid, nitrite of soda, prussiate of soda, permanganate of potash and various other chemicals.

The most important feature of the week's activities was the advance by producers on all varieties of lead acetate. Imported caustic potash continues to head the list of most active imported items. Dealers are very firm in their demands for higher prices. Yellow prussiate of potash recorded a late advance for spot goods. Commercial white arsenic has also been advanced and goods are very scarce for spot or nearby shipment. Lower prices were heard at the works on oxalic acid, the quotations for which had already discounted the effects of the new duty.

GENERAL AND SPECIAL CHEMICALS

Acetate of Lead—Manufacturers advanced prices on all varieties 1c. per lb. White crystals are now being quoted at 11½c. per lb. The demand continues to improve.

Arsenic—Prices for the white powdered are high and considerable activity has been reflected during the interval. November-December shipment sales have been made at 9½c. per lb. The insecticide industry has again come into the market and contracted as far ahead as March. Spot goods range from 9½@10c. per pound.

Bleaching Powder—Producers are quite firm in their views at 2c. per lb. f.o.b. works in large drums. Small containers were bringing up to 2¼c. per lb. Demand is generally active.

Caustic Potash—Imported 88-92 per cent is being sold around 6½c. per lb. The tone of the market is very strong and some dealers quoted higher figures. Consumers have shown added interest and leading factors recorded several carlot sales.

Caustic Soda—Export quotations were somewhat lower at $3.45@$3.50 per 100 lb. Goods for domestic consumption are bringing 3¾@4c. per lb. Contract prices remain quotably unchanged.

Chlorate of Soda—Domestic makers are quoting 6½c. per lb., f.o.b. works. Imported material is held around 6½@6¾c. per lb. A firm market with an advancing tendency is noted.

Nitrite of Soda—Imported material is obtainable in very limited lots at 9½c. per lb. The inquiry has shown considerable improvement and the general tone of this market is much firmer.

Prussiate of Potash—Spot prices have been very firm during the week and all indications point to higher levels. Several transactions were reported at 38@38½c. per lb. Supplies are very scarce and shipments seem to be around the same level as the spot market.

Prussiate of Soda—Dealers are holding stocks firm at 24@25c. per lb. The demand is very active for moderate sized quantities. Shipment prices for November-December are offered at 24½c. per lb., duty paid.

Sal Ammoniac—The white granular imported goods was quoted at 6¾@7c. per lb. Domestic factors continue to quote 7¾@8½c. per lb. The gray variety is very scarce at 7¾@8½c. per pound.

WAXES

Beeswax — Conditions surrounding this market have been of a quiet nature and prices were somewhat irregular during the interval. Supplies were around the market in larger volume, with the pure white quoted at 36@40c. per pound.

Hydrofluoric, 52 per cent	lb.	.11 – .11½	.11¾ – .12
Lactic, 44 per cent tech	lb.	.09½ – .10	.10½ – .12
Lactic, 22 per cent tech	lb.	.04½ – .04¾	.05 – .05½
Molybdic, c.p.	lb.	3.00 – 3.25	3.30 – 3.75
Muriatic, 20 deg. (see hydrochloric)			
Nitric, 40 deg	lb.	.06 – .06½	.06¾ – .07
Nitric, 42 deg	lb.	.06½ – .06¾	.07 – .07½
Oxalic, crystals	lb.	.16 – .16¼	.16½ – .17
Phosphoric, 50 per cent solution	lb.	.07½ – .08	.08¼ – .09
Picric	lb.	.20 – .22	.23 – .27
Pyrogallic, resublimed	lb.	—	1.65 – 1.75
Sulphuric, 60 deg., tank cars	ton	9 50 – 10 00	
Sulphuric, 60 deg., drums	ton	12.00 – 14.00	
Sulphuric, 66 deg., tank cars	ton	15.00 – 16.00	
Sulphuric, 66 deg., drums	ton	19.00 – 20.00	20.50 – 21.00
Sulphuric, 66 deg., carboys	ton		
Sulphuric, fuming, 20 per cent (oleum) tank cars	ton	19.00 – 20.00	
Sulphuric, fuming, 20 per cent (oleum) drums	ton	22.00 – 22.50	23.00 – 24.00
Sulphuric, fuming, 20 per cent (oleum) carboys	ton	31.00 – 32.00	33.00 – 34.00
Tannic, U. S. P.	lb.		.60 – .75
Tannic (tech.)	lb.	.40 – .45	.46 – .50
Tartaric, imported crystals	lb.	—	.31 – .31¼
Tartaric acid, imported, powdered	lb.	—	.31⅝ – .31½
Tartaric acid, domestic	lb.	—	— .32
Tungstic, per lb. of WO	lb.	—	1.00 – .110c
Alcohol, ethyl (Cologne spirit)	gal.	—	4.75 – 4.95
Alcohol, methyl (see methanol)			
Alcohol, denatured, 188 proof No. 1	gal.	—	.36 – .38
Alcohol, denatured, 188 proof No. 5	gal.	—	.36 – .38
Alum, ammonia, lump	lb.	.03½ – .03½	.03¾ – .04
Alum, potash, lump	lb.	.03½ – .03½	.04 – .04½
Alum, chrome lump	lb.	.05 – .05¼	.05½ – .06
Aluminum sulphate, commercial	100 lb.	1.50 – 1.65	1.70 – 2.25
Aluminum sulphate, iron free	lb.	.02½ – .02¾	.03 – .03¼
Aqua ammonia, 26 deg., drums (750 lb.)	lb.	.06¾ – .07¼	.07½ – .08
Ammonia, anhydrous, cyl. (100-150 lb.)	lb.	.30 – .30½	.30½ – .31
Ammonium carbonate, powder	lb.	.08½ – .08½	.09 – .09½
Ammonium nitrate	lb.	.06 – .06½	.06¾ – .07½
Amylacetate tech	gal.	—	2.35 – 2.50
Arsenic, white, powdered	lb.	.09½ – .09¾	.10 – .10½
Arsenic, red, powdered	lb.	.12 – .12¼	.12½ – .13
Barium carbonate	ton	80.00 – 82.00	83.00 – 85.00
Barium chloride	ton	105.00 –107.00	108.00 –110.00
Barium dioxide (peroxide)	lb.	.20 – .21	.21½ – .22
Barium nitrate		.09 – .09¼	.09½ – .10
Barium sulphate (precip.) (blanc fixe)	lb.	.04 – .04½	.04½ – .04¾
Blanc fixe, dry	lb.	.04 – .04½	
Blanc fixe, pulp	ton	45.00 – 55 00	
Bleaching powder	100 lb.	2.00 – 2.10	2.15 – 3.25
Blue vitriol (see copper sulphate)			
Borax	lb.	.05½ – .05¾	.06 – .06¾
Brimstone (see sulphur, roll)			
Bromine	lb.	.27 – .38	.28½ – .35
Calcium acetate	100 lb.	2.75 – 2.85	2.90 – 3.25
Calcium carbide	lb.	.04½ – .04¾	.05 – .05½
Calcium chloride, fused, lump	ton	22.00 – 23.00	23.50 – 27.00
Calcium chloride, granulated	lb.	.01½ – .01¾	.02 – .02¼
Calcium peroxide	lb.	—	1.40 – 1.50
Calcium phosphate, tribasic	lb.	—	.15 – .16
Camphor	lb.	—	.87 – .88
Carbon bisulphide	lb.	.06¾ – .07	.07½ – .07¾
Carbon tetrachloride, drums	lb.	.10 – .10¼	.10½ – .12
Carbonyl chloride, (phosgene)	lb.	—	.60 – .75
Caustic potash (see potassium hydroxide)			
Caustic soda (see sodium hydroxide)			
Chalk, precip.—domestic, light	lb.	.04½ – .04½	
Chalk, precip.—domestic, heavy	lb.	.03½ – .03½	
Chalk, precip.—imported, light	lb.	.04½ – .05	
Chlorine, gas, liquid-cylinders (100 lb.)	lb.	.05 – .05½	.05½ – .06
Chloroform	lb.	—	.25 – .32
Cobalt oxide	lb.	—	2.00 – 2.10
Copperas	ton	20.00 – 22 00	23.00 – 30.00
Copper carbonate, green precipitate	lb.	.20 – .20½	.20½ – .21
Copper cyanide	lb.	—	.58 – .600
Copper sulphate, crystals	100 lb.	5.75 – 6.00	6.10 – 6.504
Cream of tartar	lb.	—	.26 – .27
Epsom salt (see magnesium sulphate)			
Ethyl acetate com. 85%	gal.	—	.65 – .70
Ethyl acetate, pure (acetic ether, 98% to 100%)	gal.	—	.90 – .95
Formaldehyde, 40 per cent	lb.	10½ – 10¾	.11 – .11½
Fullers earth, f.o.b. mines	net ton	16.00 – 17.00	
Fullers earth—imported powdered	net ton	30 00 – 32.00	
Fuse oil, ref	gal.	—	2.75 – 2.90
Fusel oil, crude	gal.	—	1.65 – 1.85
Glauber's salt (see sodium sulphate)			
Glycerine, c.p. drums extra	lb.	—	.18 – .18½
Iodine, resublimed	lb.	—	4.40 – 4.50
Iron oxide, red	lb.	—	.12 – .18
Lead acetate, white crystals	lb.	—	.11½ – .12½
Lead arsenate, powd	lb.	.13 – .13½	.13½ – .14½
Lead nitrate	lb.	—	.15 – .20
Litharge	lb.	.07½ – .08	.08½ – .09
Magnesium carbonate, technical	lb.	06 – 06½	.06¾ – .07¾
Magnesium sulphate, U. S. P.	100 lb.	2 00 – 2.25	2.30 – 2.50
Magnesium sulphate, technical	100 lb.	—	1.00 – 1.80
Methanol, 95%	gal.	—	.70 – .71
Methanol, 97%	gal.	—	.71 – .72
Nickel salt, double	lb.	—	.11 – .11½
Nickel salt, single	lb.	—	.12 – .12½
Phogene (see carbonyl chloride)		—	—
Phosphorus, red	lb.	—	.40 – .45
Phosphorus, yellow	lb.	—	.30 – .35½
Potassium bichromate	lb.	.10 – .10½	.10½ – .11
Potassium bromide, granular	lb.	—	.17 – .23
Potassium carbonate, U. S. P.	lb.	.12 – .12½	.13 – .16
Potassium carbonate, 80–85%	lb.	.06 – .06½	.06½ – .06¾
Potassium chlorate, powdered and crystals	lb.	.07½ – .07¾	.08 – .08½
Potassium cyanide	lb	—	.55 – .57
Potassium hydroxide (caustic potash)	100 lb.	6.50 – 6 60	6.65 – 7.00
Potassium iodide	lb.	—	3.45 – 3.55
Potassium nitrate	lb.	.06½ – .06¾	.07 – .08
Potassium permanganate	lb.	.18 – .18½	.18¾ – .19
Potassium prussiate, red	lb.		.95 – 1.00
Potassium prussiate, yellow	lb.	.38½ – .38¾	.39 – .39½
Rochelle salts (see sodium potas tartrate)			
Salammoniac, white, granular	lb	.06¾ – .07	.07¼ – .07½
Salammoniac, gray, granular	lb.	.07¼ – .08	.08¼ – .08½
Salsoda	100 lb.	1.20 – 1.40	1.45 – 1.60
Salt cake (bulk)	ton	25.00 –27.00	
Soda ash, light, 58 per cent flat, bags, contract	100 lb.	1.60 – 1.67	2.00 – 2.25
Soda ash, light, 58 per cent flat, bags, resale	100 lb.	1.75 – 1.80	1.85 – 2.35
Soda ash, dense, in bags, resale	100 lb.	1.85 – 1.90	1.95 – 2.40
Sodium acetate	lb.	.08 – .08¼	.08½ – .09
Sodium bicarbonate	100 lb.	1.75 – 1.85	1.90 – 2.30
Sodium bichromate	lb.	.07½ – .07¾	.08 – .08¼
Sodium bisulphate (nitre cake)	ton	4.50 – 4.60	4.65 – 5.50
Sodium bisulphite powdered, U.S.P.	lb.	.04½ – .04½	.04¾ – .05¼
Sodium chlorate	lb.	.06½ – .06¾	.07 – .07½
Sodium chloride	long ton	12 00 –13 00	
Sodium cyanide	lb.	.19½ – .21	.21½ – .25
Sodium fluoride	lb.	.09 – .09½	.09¾ – .10
Sodium hydroxide (caustic soda) solid, 76 per cent flat, drums, contract	100 lb.	3.35 – 3.40	3.75 – 4.00
Sodium hydroxide (caustic soda) solid, 76% flat, drums, resale	100 lb.	3.45 – 3.50	3.55 – 4.00
Sodium hydroxide (caustic soda), ground and flake, contracts	100 lb.	3.80 – 3.90	4.25 – 4.40
Sodium hydroxide (caustic soda) ground and flake, resale	100 lb.	4.00 – 4.15	4.40 – 4.60
Sodium hyposulphite	lb.	.02½ – .02¾	.03 – .03½
Sodium nitrite	lb.	.09½ – .09¾	.10 – .10½
Sodium peroxide, powdered	lb.	.28 – .30	.31 – .35
Sodium phosphate, dibasic	lb.	.03¾ – .04	.04½ – .04½
Sodium potassium tartrate (Rochelle salts)	lb.	—	.18 – .21
Sodium prussiate, yellow	lb.	.24½ – .25	.25½ – .25½
Sodium silicate, (40 deg. in drums)	100 lb.	.80 – 1.00	1.05 – 1.25
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04½	.04½ – .05
Sodium sulphite, crystals	lb.	.03½ – .03⅝	.03¾ – .04½
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05½ – .06
Sulphur, crude	ton	18.00 –20 00	
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	—	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30 00 –40 00	
Talc—domestic powdered	ton	18 00 –25 00	
Tin bichloride	lb.	.10 – .10¼	.10½ – .10¾
Tin oxide	lb.	—	.39 – .40
Zinc carbonate	lb.	.14 – .14½	.14½ – .15½
Zinc chloride, gran	lb.	.06 – .06½	.06½ – .07
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.95 — $1.00
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.28 — .30
Aniline oil, drums extra	lb.	.15 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.60 — .85
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.53 — .55
Beta-naphthol, tech	lb.	.23 — .25
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.12 — .15
Ortho-cresol, in drums (100 lb.)	lb.	.16 — .18
Cresylic acid, 97–99%, straw color, in drums	gal.	.56 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.51 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.32 — .34
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.72 — .75
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.72 — .75
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.10 — .11
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.07½ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35

Nitro-toluene	lb.	$0.15	$0.10
Para-W acid	lb.	1.15	1.30
Ortho-amidophenol	lb.	2.10	2.15
Ortho-dichlor-benzene	lb.	.17	.20
Ortho-nitro-phenol	lb.	.80	.85
Ortho-nitro-toluene	lb.	.10	.13
Ortho-toluidine	lb.	.12	.14
Para-amidophenol, base	lb.	1.20	1.25
Para-amidophenol, HCl	lb.	1.25	1.30
Para-dichlorbenzene	lb.	.17	.20
Paranitroaniline	lb.	.72	.80
Para-nitrotoluene	lb.	.55	.65
Para-phenylenediamine	lb.	1.55	1.60
Para-toluidine	lb.	.85	.90
Phthalic anhydride	lb.	.35	.38
Phenol, U. S. P., drums	lb.	.21	.22
Pyridine	gal.	1.75	2.75
Resorcinol, technical	lb.	1.50	1.55
Resorcinol, pure	lb.	2.00	2.10
Salt	lb.	.55	.60
Salicylic acid, tech., in bbls	lb.	.25	.27
Salicylic acid, U. S. P	lb.	.29	.30
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.12	.14
Sulphanilic acid, crude	lb.	.24	.26
Sulidine	lb.	1.20	1.30
Toluidine, mixed	lb.	.30	.35
Toluene, in tank cars	gal.	.25	.28
Toluene, in drums	gal.	.30	.35
Xylidines, drums, 100 gal	lb.	.40	.45
Xylene, pure, in drums	gal.	.40	.45
Xylene, pure, in tank cars	gal.	.45	....
Xylene, commercial, in drums, 100 gal	gal.	.33	.35
Xylene, commercial, in tank cars	gal.	.30	....

Waxes

Prices based on original packages in large quantities f.o.b. N.Y.

Bayberry Wax	lb.	$0.19½	$0.20
Beeswax, refined, dark	lb.	.30	.32
Beeswax, refined, light	lb.	.34	.35
Beeswax, pure white	lb.	.36	.40
Candellila, wax	lb.	.34	.36
Carnauba, No. 1	lb.	.40	.42
Carnauba No. 2, North Country	lb.	.25	.26
Carnauba, No. 3, North Country	lb.	.19	.19½
Japan	lb.	.15	.15½
Montan, crude	lb.	.03¾	.04
Paraffine waxes, crude match wax (white) 105-110 m.p.	lb.	.04	.04¼
Paraffine waxes, crude, scale 124-126 m.p.	lb.	.02½	.02¾
Paraffine waxes, refined, 118-120 m.p.	lb.	.03¼	.03¼
Paraffine waxes, refined, 125 m.p.	lb.	.03¼	.03½
Paraffine waxes, refined, 128-130 m.p.	lb.	.04	.04¼
Paraffine waxes, refined, 133-135 m.p.	lb.	.04½	.04¾
Paraffine waxes, refined, 135-137 m.p.	lb.	.05	.05¼
Stearic acid, single pressed	lb.	.09	.09½
Stearic acid, double pressed	lb.	.09½	.09¾
Stearic acid, triple pressed	lb.	.10½	.10¾

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl	280 lb.	$6.45	$6.55
Rosin E-I	280 lb.	6.60	6.65
Rosin K-N	280 lb.	6.70	6.80
Rosin W. G.-W. W	280 lb.	7.75	8.25
Wood rosin, bbl	280 lb.	6.25	....
Spirits of turpentine	gal.	1.27	1.28
Wood turpentine, steam dist	gal.	1.15	....
Wood turpentine, dest. dist	gal.	1.12	.70
Pine tar pitch, bbl	200 lb.	.....	6.00
Tar, kiln burned, bbl. (500 lb.)	bbl.	.....	9.50
Retort tar, bbl	500 lb.		9.00
Rosin oil, first run	gal.	.38	....
Rosin oil, second run	gal.	.41	....
Rosin oil, third run	gal.	.48	....
Pine oil, steam dist., sp.gr., 0.930-0.940	gal.		1.00
Pine oil, pure, dest. dist	gal.		.95
Pine tar oil, ref., sp.gr. 1.025-1.035	gal.		.46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla	gal.		.35
Pine tar oil, double ref., sp.gr. 0.965-0.990	gal.		.75
Pine tar, ref., thin, sp.gr., 1.080-1.960	gal.		.25
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990	gal.		.25
Pinewood creosote, ref	gal.		.52

Fertilizers

Prices remain quotably unchanged

Crude Rubber

Quotations same as previous report

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls	lb.	$0.12½	$0.13
Castor oil, AA, in bbls	lb.	.13	.13½
China wood oil, in bbls	lb.	.12½	.12¾
Cocoanut oil, Ceylon grade, in bbls	lb.	.08¼	.08⅜
Cocoanut oil, Cochin grade, in bbls	lb.	.08⅜	.09
Corn oil, crude, in bbls	lb.	.09¼	.10
Cottonseed oil, crude (f. o. b. mill)	lb.	.07¼	.07½
Cottonseed oil, summer yellow	lb.	.11½	.11⅝
Cottonseed oil, winter yellow	lb.	.12	.12¼
Linseed oil, raw, car lots (domestic)	gal.	.87	.88
Linseed oil, raw, tank cars (domestic)	gal.	.84	.85
Linseed oil, boiled, in 5-bbl lots (domestic)	gal.	.90	.91
Olive oil, denatured	gal.	1.15	1.17
Palm, Lagos	lb.	.06¾	.07
Palm, Niger	lb.	.06	.06¼
Peanut oil, crude, tank cars (f.o.b. mill)	lb.	.08½	.08¾
Peanut oil, refined, in bbls	lb.	.12	.12¼
Rapeseed oil, refined in bbls	gal.	.78	.80
Rapeseed oil, blown, in bbls	gal.	.86	.87
Soya bean oil (Manchurian), in bbls. N. Y.	lb.	.11½	....
Soya bean oil, tank cars, f.o.b., Pacific coast	lb.	.09½	.09¾

FISH

Light pressed menhaden	gal.	$0.51	....
White bleached menhaden	gal.	.54	.55
Blown menhaden	gal.	.61	....
Whale Oil, No. 1. crude, tanks, coast	gal.	.45	.48

Miscellaneous Materials

Asbestos, crude No. 1, f.o.b., Quebec, Canada	short ton	$600.00	$800.00
Asbestos, shingle stock, f.o.b., Quebec, Canada	short ton	65.00	80.00
Asbestos, cement stock, f.o.b., Quebec, Canada	short ton	15.00	17.00
Shellac, orange fine	lb.	.61	.62
Shellac, orange superfine	lb.	.63	.64
Shellac, A. C. garnet	lb.	.62	.63
Shellac, T. N	lb.	.56	.57

All other prices remain quotably unchanged

Ferro-Alloys

Ferrotitanium, 15-18%, f.o.b. Niagara Falls, N. Y	net ton	$200.00	$225.00
Ferrochromium, per lb. of Cr contained, 6-8% carbon, carlots	lb.	.10	10½
Ferrochromium, per lb. of Cr contained, 4-6% carbon, carlots	lb.	.10½	.11
Ferromanganese, 78-82% Mn, domestic	gross ton	69.00	72.00
Spiegeleisen, 19-21% Mn	gross ton	38.00	39.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo	lb.	2.00	2.50
Ferrosilicon, 10-15%	gross ton	38.00	40.00
Ferrosilicon, 50%	gross ton	63.00	65.00

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

PHOENIX—The Southwestern Portland Cement Co., El Paso, Tex., has preliminary plans under way for the erection of a new plant on site selected near Phoenix, to consist of a number of buildings, with power house, etc., estimated to cost about $1,200,000, including machinery. The new mill will give employment to a working force of about 200 men, and will be operated as a branch of the main plant at El Paso. O. J. Binford is secretary and general manager.

Alabama

BIRMINGHAM—The McWane Cast Iron Pipe Co., Birmingham, has awarded a contract to the Ingalls Iron Works, Birmingham, for the erection of the first unit of its proposed new plant on property recently acquired at East Birmingham, to be 105 x 340 ft., and equipped as a foundry for the production of cast iron pipe of small size. Other foundry units will be built at a later date. J. R. McWane is president.

Arkansas

MCRAE—The Reynolds Brothers Co. has tentative plans under consideration for the erection of a new plant on local site for the manufacture of brick, tile and other burned clay products.

California

LOS ANGELES—The Pacific Coast Borax Co., Kohl Bldg., San Francisco, has plans nearing completion for the erection of the initial unit of its proposed new plant in the harbor district, on site recently acquired, to be 2-story, 250x400 ft., with foundations to provide for the constructionn of three additional stories at a later date. With other projected structures, the plant will cost close to $1,000,000, including machinery. Albert C. Martin, Higgins Bldg., Los Angeles, is architect.

Connecticut

NORWALK—The Meeker Union Foundry Co. has awarded a contract to the T. J. Pardy Construction Co., Bridgeport, for the erection of a new 1-story foundry, for the manufacture of iron castings.

Georgia

ATLANTA—The Vulcanite Roofing Co., Beaver Rd., Buffalo, N. Y., a subsidiary of the Beaverboard Companies, same address, has tentative plans under consideration for the erection of a new local plant for the manufacture of composition roofing products. A site is being selected.

Illinois

CHICAGO—The Benedict Stone Corp., 33 West 42nd St., New York, N. Y., manufacturer of composition stone products, has preliminary plans in progress for the erection of a new branch plant at Chicago. It is proposed to organize a subsidiary company to operate the works. The parent organization is arranging to increase its capital, the proceeds to be used for general expansion.

ELGIN—Construction has been commenced on a new 1-story foundry at the plant of the Woodruff & Edwards Co., State St., manufacturer of hardware products, to be 50x100 ft., and estimated to cost approximately $100,000, including equipment.

Louisiana

MONROE—Thomas Stilwell, Anderson, Ind., associated with interests connected with the Lippincott Glass Co., Hartford City, Ind., is perfecting plans for the operation of a local plant for the manufacture of chimneys and kindred blown glass products. Another plant will be operated at Cedar Grove, La. The operating companies will be of co-operative character.

Maryland

BALTIMORE—The Solarine Co., Emerson Bldg., manufacturer of metal polishes, etc., has awarded a contract to Frainie Brothers & Haigley, 19 West Franklin St., for the erection of its proposed 1-story plant at Eagle and Smallwood Sts., estimated to cost close to $100,000, including machinery. E. H. Glidden, American Bldg., is architect. Harry A. Allers is president.

Massachusetts

EVERETT—The Stone & Forsyth Co., 67 Kingston St., Boston, manufacturer of paper products, has awarded a contract to the Blake & Pope Co., 50 State St., Boston, for the construction of an addition to its mill on Spring St., Everett, to be 2-story, 41x75 ft.

MALDEN—In connection with its new local plant building, for which contract recently was let, Wadsworth, Howland & Co. Inc., 139 Federal St., Boston, manufacturer of paints, varnishes, etc., is arranging an appropriation of approximately $600,000 for the construction of a number of other plant units. Plans will be prepared at an early date. A research laboratory will be established in connection with the plant. The company has acquired the Ocean Paint Works, Inc., 211 47th St., Brooklyn, N. Y., and will operate this factory as a subsidiary; the plant has a capacity of about 1,000 gal. per day.

Michigan

MUSKEGON—The Central Paper Co. is completing plans for the construction of a new 3-story addition to its mill on Richard St., estimated to cost approximately $200,000, with machinery. E. J. Gaddes is secretary.

DETROIT—The Austin-Kelly Ink Co., 2270 Franklin St., has filed plans for the construction of a new 2-story plant on Bellevue Ave., near Sylvester St., estimated to cost approximately $30,000.

MONROE—Plans are being completed for the construction of a new 1-story foundry addition at the plant of the Monroe Auto Equipment Co., to be 40x60 ft. Bids will soon be asked. A. F. Meyer is president.

SAGINAW—The Saginaw Chemical Co., 1618 North Michigan Ave., has preliminary plans under consideration for the construction of a plant on South Michigan Ave., consisting of two 1-story buildings, 68x100 ft. and 30x40 ft. respectively, estimated to cost about $50,000. It is expected to call for bids early in the coming year. James C. Graves is vice-president.

Missouri

ST. LOUIS—The Reardon Co., 2200 South 2nd St., manufacturer of glue, paints and kindred products, has awarded a general contract to Hirsch & Co., Wainwright Bldg., for the construction of a 3-story and basement plant addition at 2nd and Clinton Sts., 40x80 ft., to cost approximately $50,000. H. G. Clymer, Wainwright Bldg., is architect.

SPRINGFIELD—The Springfield Tanning Co., 214 Holland Bldg., formerly known as the Southwestern Tanning Co., has awarded a contract to the Pauly Construction Co., 741 South Ave., for the erection of its proposed 1-story and basement leather tanning plant, 100x135 ft., on West Commercial St. Work will be placed under way at once. W. R. Wolfe heads the company.

New Jersey

TRENTON—The New Jersey Porcelain Co., Pennsylvania and Mulberry Sts., has acquired a tract of property, fronting on New York Ave., extending from Strawberry to Plum St., as a site for the construction of a new plant. Plans will be prepared at an early date.

STOCKTON—The B. C. Tillinghast Rubber Mfg. Co., recently organized under state laws, has acquired the local plant of the Stockton Rubber Co., which has been under control of a receiver for more than a year past. The new owner will make immediate improvements, including the installation of new machinery to cost about $25,000. Employment will be given to about 50 persons for initial operations. Williams J. McLaughlin is vice-president and general manager; and Dominick Price, secretary and treasurer.

New York

NEW YORK—The Corn Products Refining Co., 17 Battery Place, has plans under consideration for extensions and improvements in its refining plants at Edgewater, N. J., and Pekin and Argo, Ill., to include the construction of new buildings and the installation of additional equipment. It is said that a fund of about $3,000,000 has been arranged for the expansion. The company will also enlarge its plants in France and Germany, estimated to cost in excess of $1,000,000, with equipment.

GOUVERNEUR—The Aldridge Paper Co., First National Bank Bldg., is considering plans for the construction of a new local plant, to cost about $35,000. N. R. Caswell is head.

NEW YORK—The J. Spaulding & Sons Co., 484 Broome St., manufacturer of fiber products, will soon break ground for addition to building at its plant on Wheeler St., Tonawanda, to cost about $150,000, including machinery. The new structures will supplement a plant addition now practically completed, representing a cost of close to $250,000. Plans are being prepared by George F. Hardy, 309 Broadway, New York, is engineer.

BUFFALO—Robert J. Gray, Dart St., near Bradley St., has made application to the city council for permission to equip a building at the location noted for a sherardizing plant, for zinc galvanizing and kindred work.

Ohio

NEWCOMERSTOWN—The Canton Brick & Tile Co., New Philadelphia, O., is completing plans and will soon break ground for the construction of a 1- and 2-story plant on the Hardy Asher estate property recently acquired. It will consist of a number of buildings, estimated to cost about $250,000, with machinery. W. H. Demuth heads the company.

BEDFORD—The Mason Tire & Rubber Co., Kent, O., has plans in progress for enlargements at the plant of the Owen Tire & Rubber Co., Bedford, recently acquired. It is proposed to increase the capacity from 500 to 1,500 tires a day. The company has arranged for a bond issue of $2,000,000, a portion of the fund to be used for the expansion.

NILES—The Brier Hill Steel Co., Youngstown, O., has plans in progress for the construction of proposed additions to the Thomas plant at Niles, to increase the capacity approximately 25 per cent. The installation will comprise new annealing furnaces, rolling mill equipment and other machinery, and is estimated to cost about $1,000,000, including buildings. A fund of this amount has been appropriated.

Oklahoma

BLACKWELL—The Tower Gasoline Co., Oklahoma City, has preliminary plans under consideration for the construction of a new oil refinery on local site, to include a gasoline absorption plant. It is also proposed to construct additions to a number of present gasoline works in other districts. L. Z. Harrison is general manager.

HOLDENVILLE—Charles Morris, Holdenville, is organizing a company to construct and operate a local plant for the manufacture of brick, tile and kindred burned clay products.

Pennsylvania

PITTSBURGH—The Stroh Steel Hardening Process Co., Westinghouse Bldg., will construct by day labor its proposed new plant at Chateau and Ridge Sts., to consist of a number of buildings, including foundry for the production of steel castings. The plant will cost about $250,000, with equipment. W. Y. Stroh is president.

CLARION—The Berney-Bond Glass Co. is said to have tentative plans under way for the rebuilding of its local plant

estroyed by fire, Sept. 24, with loss estiated at close to $400,000, including equipent. The works have been giving mployment to about 200 operatives.

PHILADELPHIA—The Wilmot Fleming Iron Steel Co., recently organized by Wilmot leming, 956 Foulkrod St., has preliminary lans in progress for the construction of a ew 1- and 2-story plant on site selected at ottman and G Sts., estimated to cost in xcess of $50,000. It will be equipped for he manufacture of general steel products. Ir. Fleming heads the company, and will ct as engineer for the works. Others inerested in the company are Paul E. Good nd Joseph J. Carr.

PHILADELPHIA—The Paper Manufacturrs' Co., 526 Cherry St., is razing the uilding at 5th, Willow and Randolph Sts., o make way for the construction of a ew 5-story mill, estimated to cost in xcess of $75,000. Clarence C. Wunder, 415 Locust St., is architect. Francis A.)'Neill is president.

EPHRATA—The Borough Council is aranging an ordinance providing an appro- riation of $30,000 for the construction of filtration plant at the municipal waterorks.

Tennessee

KINGSPORT—The Mead Fibre Co. has warded a general contract to W. A. Allen, Kingsport, for the construction of its proosed 2-story and basement mill addition, 5x275 ft., to be equipped for the manuacture of paper products and for finishing work. . The structure is estimated to cost bout $350,000, with machinery. The Management, Engineering & Development Co., Callahan Bank Bldg., Dayton, O., is rchitect and engineer, and will prepare lans for other future extensions estimated o bring the investment close to $1,000,000.

CHATTANOOGA—The Debois Tube & Rubber Co. has preliminary plans in progress or plant enlargements to more than double he present capacity. The expansion is stimated to cost in excess of $75,000.

Texas

HEARN—The Travis Cottonseed Products Co. is reported to be planning for the ebuilding of its oil mill, destroyed by fire, Sept. 17, with loss estimated in excess of 100,000, including machinery.

HOUSTON—The Armstrong Steel Co., Fort Worth, is selecting a local site for the construction of a plant for the manufacture of steel products, to consist of an open-hearth urnace, mills and other structures, estinated to cost approximately $1,000,000. The plant will be equipped for an annual roduction of about 60,000 tons. The present Fort Worth mills, with rated capacity f 40,000 tons per year, will be continued n operation. R. L. Van Zandt is president.

Utah

NEPHI—The Nephi Plaster & Mfg. Co. as plans under way for enlargements in ts mill, to include the construction of a omplete plant unit for the manufacture f agricultural gypsum products. The equipment installation will comprise grinding nd crushing machinery, screening apparatus, power equipment, etc. The work is stimated to cost in excess of $50,000.

Virginia

FREDERICKSBURG—The National Tanning Extract Corp. has acquired a local building, formerly used by the Wilson Dye Works, nd will occupy the structure for the manufacture of tanning extracts. Improvements will be made and equipment installed at an early date.

HOPEWELL — The Hummel-Ross Fibre Corp. has awarded a contract to the Wise Granite & Construction Co., American Bank Bldg., Richmond, for the construction of a 1- and 2-story plant, estimated to cost close o $100,000, with machinery. The Joseph H. Wallace Co., 5 Beekman St., New York, N. Y., is architect and engineer.

Washington

SEATTLE—The Washington Iron Works, Inc., has awarded a contract to the Austin Co., Smith Bldg., for the construction of a 1-story foundry approximating 65,000 sq.ft. f floor space, to be equipped for the production of steel and gray iron castings.

MICA—The American Firebrick Co., Mica, near Spokane, has plans under way for the rebuilding of the portion of its No. 2 plant, recently destroyed by fire, with loss of about $35,000, including equipment.

MT. VERNON—The Star Brick & Tile Co., Bay View, near Mt. Vernor, will soon commence the rebuilding of the portion of its plant, recently destroyed by fire, with loss approximating $25,000, including equipment. C. B. Mayhew heads the company.

West Virginia

CHARLESTON — The Libbey-Owens Co., Nicholas Bldg., Toledo, O., has plans in progress for the construction of six new additions to its local plant, ranging from 2-story, 45x240 ft. in size to smaller structures. The expansion is estimated to cost close to $300,000, including equipment. A complete cutter shop will be installed. The DeVore Co., 908 Nicholas Bldg., Toledo, is architect and engineer. E. D. Libbey heads the company.

Wisconsin

GREEN BAY—The Fort Howard Paper Co. has commenced excavations for a new 2-story and basement building, 100x140 ft., at its plant, to cost about $75,000. The general building contract has been let to the H. J. Selmer Co., McCartney National Bank Bldg.

MILWAUKEE — The Jelinek - Krueger Leather Goods Co., 416 4th St., is planning for the rebuilding of the portion of its plant, destroyed by fire, Sept. 9, with loss estimated at about $25,000.

Canada

CALGARY, ALTA.—The Imperial Oil Corp., 347 Madison Ave., New York, N. Y., has tentative plans under consideration for the construction of a new oil refinery at Calgary, with gasoline extraction plant, designed for a capacity of about 2,500 bbl. per day. The initial plant will give employment to more than 200 men, and is estimated to cost close to $2,000,000, with machinery. It is expected to commence construction early in the coming spring.

Capital Increases, Etc.

THE TRENTON LIME CO., Remsen, N. Y., has filed notice of increase in capital from $40,000 to $625,000, for proposed expansion.

THE LUDINGTON RUBBER CO., Ludington, Mich., has filed notice of dissolution under state laws.

THE MCLAURIN-JONES CO., Brookfield, Mass., a consolidation of the Ideal Coated Paper Co., Brookfield; Ware Coated Paper Co., Ware, Mass.; and the Samuel Jones Co., Newark, N. J., specializing in the production of gummed papers, has arranged for a bond issue of $400,000, the proceeds to be used for expansion and additions to working capital.

THE PEEL CHEMICAL CORP., 19 North Moore St., New York, N. Y., has filed notice of increase in capital from $200,000 to $450,000.

THE ENAMELED STEEL SIGN CO., 190 North State St., Chicago, Ill., has filed notice of increase in capital from $50,000 to $100,000.

THE ATLAS STEEL CORP., Dunkirk, N. Y., has been organized under state laws with a capital of 1,000 shares of stock, no par value, to take over and merge the Atlas Crucible Steel Co., Dunkirk, and the Electric Alloy Steel Co., Charleroi, Pa. Plants will be operated at the two places noted, and at Welland, Ont. Louis J. Campbell is head of the consolidated company.

THE EASTERN SUGAR CORP., a subsidiary of the Cuba Cane Sugar Corp., 112 Wall St., New York, N. Y., operating a refinery in Cuba, known as the Violeta Mill, has arranged for a bond issue of $10,000,000, a portion of the proceeds to be used for expansion and additions to working capital. W. E. Ogilvie is president.

R. RICHARDSON HILL & CO., INC., Saginaw, Mich., a Delaware corporation, has filed notice of change of name to the Old Hickory Dye-Chemicals Co., at the same time increasing its capital from $300,000 to $650,000.

THE GRAND RAPIDS GLUE CO., Grand Rapids, Mich., has filed notice of dissolution under state laws.

THE WHITELEY MALLEABLE CASTINGS CO., Muncie, Ind., has filed notice of dissolution under state laws.

THE SEAMAN PAPER CO., 208 South La Salle St., Chicago, Ill., has filed notice of increase in capital from $3,000,000 to $4,000,000.

THE GILL & HALL CO., Salem, Mass., manufacturer of leather products, has filed notice of dissolution.

THE CHOCTAW COTTON OIL CO., Ada, Okla., is planning for an increase in capital to $2,500,000 for proposed expansion.

THE SUGAR ESTATES OF ORIENTE, INC., affiliated with the West India Sugar Finance Corp., 129 Front St., New York, N. Y., operating three sugar refineries in the Province of Oriente, Cuba, has arranged for a bond issue of $6,000,000, for general operations, expansion, etc. Thomas A. Howell is president.

THE TRI-STATE PULP & PAPER CORP., High Bridge, N. J., has filed notice of increase in capital from $8,000,000 to $13,200,000.

THE MAGNA METAL CORP., Doremus Ave., Newark, N. J., has been reorganized with a capital of $100,000, to manufacture a special metal similar to aluminum, and said to be lighter and stronger than such material. The operation of the present plant will be continued.

THE ARMSTRONG CORK CO., Pittsburgh, Pa., has called a special meeting to approve an increase in capital from $17,000,000 to $30,000,000.

THE UTILITY COLOR & CHEMICAL CO., 700 Broad St., Newark, N. J., has filed notice of dissolution.

THE DUNLOP RUBBER CO., River Rd., Buffalo, N. Y., is said to be planning for a bond issue of $10,000,000, for general operations, expansion, etc.

C. G. Ludvigh has been appointed receiver for the FLOROME CHEMICAL CORP., 24 Wooster St., New York, N. Y.

THE ARMOUR LEATHER CO., Chicago, Ill., has taken title to the plant and business of Alexander Brothers, Inc., Philadelphia, Pa., manufacturer of leather products, for a cash consideration said to be $806,000.

Robert A. Messler has been appointed receiver for the TRENT BRICK CO., Brunswick Ave., Trenton, N. J.

Industrial Developments

LEATHER—The American Hide & Leather Co., New York, has adopted a full-capacity schedule at its side leather plant at Ballston Spa. N. Y. The Woburn, Mass., tannery of the company, devoted to patent leather production, has been advanced to about 75 per cent of normal. The Western plants are increasing their operating schedules, with the Sheboygan, Wis., tannery running on a 70 per cent production basis.

Howe Brothers, Boston, Mass., are arranging for increase in operations at their sole leather tanneries.

The American Oak Leather Co., Boston, Mass., is said to be arranging for the removal of its cutting plant from South St. to a building on Congress St., for immediate increased production.

The Crescent Leather Co., Woburn, Mass., manufacturer of patent leather, has advanced operations to a working basis of about 1,000 sides a day.

RUBBER—The Dayton Rubber Mfg. Co., Dayton, O., is running full at its local plant, with monthly averages higher than ever before in the history of the company.

The Republic Rubber Co., Youngstown, O., is advancing production at its local mills. It is expected to resume operations in full at the tire-manufacturing department within a few weeks. The Canton, O., mill of the company is now running on a normal basis, with regular working force.

After a number of weeks idleness, John P. Hill, receiver for the Hydro United Tire Co., Pottstown, Pa., has reopened the plant on a basis of 600 tires a day, giving employment to a working force of about 300 persons.

The Goodyear Tire & Rubber Co., Akron, O., is resuming normal production at its No. 2 plant, devoted to the manufacture of tires for Ford automobiles, following the recent curtailment.

PAPER—The York Haven Paper Co., York Haven, Pa., is running under heavy production, giving employment to a regular working force. A 10 per cent wage increase has been made at the mill, effective Oct. 1.

The American Writing Paper Co., Holyoke, Mass., has advanced production at its different state mills, and is now operating in excess of 85 per cent of capacity.

The Castanea Paper Co., Lock Haven, Pa., has increased the wages of operatives at its local mill. All departments are running full.

The Alaska Pulp & Paper Co. has resumed operations at its Speel River, Alaska, mill, following a suspension for some time past. It is expected to keep the plant in service throughout the winter.

The New York & Pennsylvania Co., Lock Haven, Pa., is maintaining active production in all departments at its local mill. A wage advance of 3c. an hour has been granted employees.

OIL—The Wortham Refining Co., Wor-

tham, Tex., is planning for the early resumption of operations at its local petroleum refinery, following a curtailment for a number of weeks past.

The Mexico Petroleum Co., New York, is operating its refining plant at Tampico, Mexico, at maximum capacity, and expects to continue on this basis for an indefinite period.

The Skelly Oil Co., Midland, Okla., is operating in all departments at its refineries and byproducts plants. An average of 75,000 bbl. of crude oil per month is being run through the stills, with output devoted to fuel oil, kerosene, gasoline, naphtha distillate, gas oil and lubricating oils.

IRON AND STEEL—The Cleveland-Cliffs Iron Co., Cleveland, O., is arranging for the resumption of operations at its iron and chemical plants at Gladstone, Mich., on Oct. 15, following a suspension for some time past. This will be the last charccal furnace to be placed in blast in the state, making 100 per cent operation of such furnaces for the first time since 1920.

The Carnegie Steel Co., Youngstown, O., has placed its Lower Mill furnace in blast, bringing production to close to 100 per cent in this district. Only one company furnace is now idle.

The United States Steel Corp. is increasing production at its mills in the Wheeling, W. Va., district to close to normal. The Wheeling Steel Co. and the Whitaker-Glessner Co. mills in this section are also running full. The Yorkville, O., plant of the Wheeling company is now on a 75 per cent operating basis.

The Gulf States Steel Co., Birmingham, Ala., has advanced the wages of employees at its Gadsden, Ala., plant, 10 per cent. About 2,000 men are affected. This makes the second such increase within the past three months. The mill is running full.

The Nagle Steel Co., Pottstown, Pa., recently organized with a capital of $300,000 by George H. Heck, 518 Commercial Trust Bldg., Philadelphia, Pa., and associates, has taken over the plants of the company of the same name at Pottstown and Seyfert, Pa., secured from the receiver. The new company has resumed production at the Pottstown mill under double shift working force, and plans to reopen the Seyfert plant before the close of the month.

The Republic Iron & Steel Co., Youngstown, O., is making ready for operation at the fifth furnace at its Hazleton plant. Four units are now in blast. Work is also under way at its Hanna furnace, and this unit will soon be blown in.

The Reading Iron Co., Reading, Pa., has placed its local sheet mill in operation, giving employment to about 250 men. The plant has been idle for about 6 weeks past.

The Midvale Steel & Ordnance Co. is arranging for the immediate blowing in of the second blast furnace at its Coatesville, Pa., plant.

New Companies

THE ASTOR CHEMICAL CORP., New York, N. Y., care of Bickerton, Willenberg & Fleischer, 220 West 42nd St., representatives, has been incorporated with a capital of $10,000, to manufacture chemicals and chemical byproducts. The incorporators are L. E. Meyers, B. White and E. Weisberg.

THE SOUTHERN TANNING & MFG. CO., Punta Gorda, Fla., has been incorporated with a capital of $50,000, to manufacture leather products. J. T. Swinney is president; T. C. Crosland, vice-president; and W. W. Knight, secretary-treasurer, all of Punta Gorda.

THE COLONIAL BRICK CO., Cliffwood, N. J., care of Fred Hankins, Cliffwood, representative, has been incorporated with a capital of $100,000, to manufacture brick, tile and other burned clay products. The incorporators are Orman W. Ketchum, Frank J. Bell and George M. Craigen, all of Cliffwood.

THE FIXEM MFG. CO., Detroit, Mich., has been incorporated with a capital of $35,000, to manufacture special powders, chemical specialties, etc. The incorporators are Carl Wrobel, M. Peters and Alfred P. Norton, 3066 Van Dyke Ave., Detroit.

THE AMERICAN JAPANNING CO., Woburn, Mass., has been incorporated with a capital of $10,000, to manufacture japanned metal products, etc. James J. Finnegan is president; and Samuel Gorin, 9 Allen St., Boston, treasurer.

THE INTERCONTINENTAL RUBBER PRODUCTS CORP., New York, N. Y., care of the Registrar & Transfer Co., 900 Market St., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $6,040,000, to manufacture rubber products.

THE FIMA LABORATORIES, INC., Rochester, N. Y., care of G. B. Wesley, attorney, Rochester, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are W. Mathie, R. J. Fisher and H. E. Moore, all of Rochester.

THE MICHIGAN STEEL CORP., Jersey City, N. J., care of the Corporation Trust Co., 15 Exchange Place, Jersey City, representative, has been incorporated under state laws to manufacture steel sheets and other steel products. The capital is 22,000 shares of stock, no par value.

THE EAST-WEST FEFINING CO., Los Angeles, Calif., care of James Westervelt, 522 Citizens National Bank Bldg., Los Angeles, representative, has been incorporated with a capital of $100,000, to manufacture refined petroleum products. The incorporators are Fred S. Wilson and George B. Clark, Santa Monica, Calif.; and S. R. Harding, Los Angeles.

THE OSTRO PRODUCTS CORP., Jersey City, N. J., care of the United States Corporation Co., 15 Exchange Place, Jersey City, representative, has been incorporated under state laws with capital of 500 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are William E. Lake and James B. L. Orme.

THE EMPIRE DRAWN STEEL CORP., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws with capital of $3,750,000, to manufacture steel products.

THE SWIHALL MFG. CO., 410 Rush St., Chicago, Ill., has been incorporated with a capital of $25,000, to manufacture rubber specialties. The incorporators are A. E. Anderson and Oscar W. Anderson.

THE WIRE FIBROUS PRODUCTS CO., Jersey City, N. J., care of the Corporation Trust Co., 15 Exchange Place, representative, has been incorporated with a capital of $1,000,000, to manufacture fiber products.

THE LIBERTY PAINT PRODUCTS CO., care of the Colonial Charter Co., Ford Bldg., Wilmington, Del., representative, has been incorporated with a capital of $100,000, under Delaware laws, to manufacture paint, varnish and kindred products.

THE Z. G. V. CHEMICAL PRODUCTS CO., Kearny, N. J., has been incorporated with a capital of $100,000, to manufacture chemicals and chemical byproducts. The incorporators are Robert E. Van Order, John E. Zellers and Lovett A. Grant, Jacobus Ave., Kearny. The last noted represents the company.

THE OSWEGATCHIE PAPER CO., Gouverneur, N. Y., has been incorporated with a capital of $200,000, to manufacture paper products. The incorporators are S. B. and A. F. Wardwell and E. B. Sterling. The company is represented by Cobb, Cosgrove & Kimball, Watertown, N. Y.

THE LIMESTONE BRICK CO., Boston, Mass., has been incorporated with a capital of $100,000, to manufacture sand-lime brick and kindred products. Robert J. Cram is president; and Drew B. Hall, 20 Georganna St., Braintree, Mass., treasurer. The last noted represents the company.

THE SENECA PETROLEUM CORP., care of the Corporation Service Co., Equitable Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $1,000,000, to manufacture petroleum products.

THE BURKE-HUMPHREYS PRODUCTS CO., New York, N. Y., care of F. A. McKenzie, 305 Broadway, New York, representative, has been incorporated with a capital of $25,000, to manufacture chemicals and chemical byproducts. The incorporators are C. Humphreys and J. H. Burke.

THE AUTOCESSORIES CHEMICAL CO., Waterbury, Conn., has filed notice of organization to manufacture special chemical products for automotive service. W. B. Price and R. W. Belfit, both of Waterbury, head the company.

THE WAVERLY RENDERING & BYPRODUCTS CO., Newark, N. J., care of the New Jersey Registration & Trust Co., 525 Main St., East Orange, N. J., representative, has been incorporated with a capital of $125,000, to manufacture greases, lubricating products, etc.

THE LITTLEFIELD-SEGAL LEATHER CO., Peabody, Mass., has been incorporated with a capital of $20,000, to manufacture leather products. Arthur S. Littlefield is president; and Chapin Segal, Abington, Mass., treasurer. The last noted represents the company.

THE MINTER CITY OIL MILL, INC., Minter City, Miss., has been incorporated with a capital of $30,000, to manufacture cottonseed oil products. The incorporators are M. F. Sturtivant and T. C. Buford, both of Minter City.

THE FUSETITE CORP., Watertown, N. Y., has been incorporated with a capital of $100,000, to manufacture cement products. The company is a subsidiary of the Northern New York Utilities Co., Watertown. The incorporators are H. and N. A. Young, and F. A. Rogers, Watertown.

THE DUNBAR CANE PRODUCTS CORP., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, representative, has been incorporated under Delaware laws with capital of $11,000,000, to manufacture sugar products.

THE BACON HILL BRICK CO., Atlantic City, N. J., has been incorporated with a capital of $100,000, to manufacture brick, tile and other burned clay products. The incorporators are S. A. Burris and John C. Slape, 446 Guarantee Trust Bldg., Atlantic City. The last noted represents the company.

THE WILLIAMS LIME MFG. CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under Delaware laws, with capital of $100,000, to manufacture lime and kindred products.

THE CO-OPERATIVE CUT GLASS WORKS, 446 Ash St., New Bedford, Mass., have filed notice of organization to manufacture glass produces. G. G. Enos, 46 Holden St., New Bedford, heads the company.

THE FOURLOCK TILE CORP., Ridley Park, Pa., has been incorporated with a capital of $20,000, to manufacture ceramic tile products. The incorporators are David Hennis, James G. Cooke and William R. Calligan, 15 East Felton St., Ridley Park. The last noted represents the company.

THE ALLEN COUNTY OIL CO., Scottsville, Ky., has been organized under state laws to manufacture petroleum products. The incorporators are Guy S. Amos and E. J. Lee Rust, Birmingham, Ala.; and C. W. Hill, and B. A. Hale, both of Scottsville.

Coming Meetings and Events

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

TANNERS' COUNCIL will hold its annual meeting Oct. 19 and 20 at the Congress Hotel, Chicago.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, 52 East 41st St., New York City: Oct. 13—Société de Chimie Industrielle, regular meeting. Oct. 20—Society of Chemical Industry, Grasselli Medal. Nov. 10—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting. Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting, May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

ne Chemical Exposition, or Two?

RESENT indications are that two chemical expositions will bid for the favor and patronage of the emical industry in 1923. As intimated in our litorial comment of September 27, a rival exposition as proposed even before the Eighth National Exposion of Chemical Industries was closed. And now the ew project has been formally launched as the Chemal Industries Exposition, sponsored in its organizaon by ADRIAAN NAGELVOORT. Briefly, it is based on he co-operative principle, the exhibitors being *ipso acto* members. A board of directors is to manage the usiness.

Holding no brief for any particular exposition comany or organization, and having in mind only the est interests of the industry, we are glad to give space sewhere in this issue to a statement by Mr. NAGELOORT in which he gives the reasons, as he sees them, at call for an exposition modeled on new lines. With uch that he says we are in hearty accord. An exposion management should be in lively contact with the xhibitors, and the chemical industries *per se* should be ell represented in a chemical exposition. Further, the emical industry still needs an exposition as a great ducational force in driving home the interrelation and nterdependence of its constituent parts, and its bearng as a whole on the national welfare.

Following Mr. NAGELVOORT thus far, we come to a oint of divergent opinion when he holds that a coperative body is essential to a well-rounded, successful xposition, and that a commercial enterprise under proessional management cannot, or is not likely to, achieve is end. There is room for a difference of opinion, ecause there are successful co-operative expositions, lthough they are conducted along slightly different nes than those hitherto adopted in the National Expoition of Chemical Industries. Our own opinion has een previously expressed on two occasions, following he seventh and eighth expositions respectively. And us far we see no reason for changing our fundaental position. Mr. NAGELVOORT may prove us wrong, ut as a matter of policy we should prefer to labor ith the present management in an effort to improve s methods and results, rather than force a division f the industry by opening a rival show. This would eem to be the part of wisdom, at least until the resent management proves so utterly incompetent, r so stiff-necked and obstinate, as to make success mpossible. And since, in our judgment, we have not egun to approach that point, we deprecate the posibility of two expositions.

For eight years the chemical show has been an anual affair. The current intervening year is still oung, and no man can foresee what it will bring forth. Is it hopeless to believe that subsequent events will point the way to a unification of interests and a happy acceptance of ideas that will give us one great exposition representative of the chemical industry of the United States? We think not.

European Conditions As We See Them

WORD pictures of conditions in Europe have almost become the order of the day. With each returning ship fresh travelers add either to the clarity or confusion of ideas, according as their experience has been deep or casual, biased or disinterested. Each attempts, and no doubt achieves a measure of success in his efforts, to portray conditions as he saw them; but the criterion of the value of his conclusions must be the facilities he enjoyed for observation, the extent to which he was able to delve beneath the superficial aspect of affairs and fortify his judgment with essential and significant facts.

At the risk of adding one more note to the concert of American opinion on Europe, but with confidence that it will prove enlightening as well as harmonious, we begin publication in this issue of a series of short articles, impressions of European conditions, by Mr. J. S. NEGRU, Managing Editor of *Chem. & Met.* For six months, from February to August of this year, he traveled the central European countries, Belgium, France, Italy, Switzerland and Germany, as a representative of this magazine for the purpose of learning at first hand the facts in the technical, economic and social affairs of those countries. Our purpose was to afford the business and professional clientèle of *Chem. & Met.* an opportunity to view through an engineer's eyes the things about which merchants, bankers, economists and other groups of our population had been writing from their respective points of view. There is value and advantage in getting opinions on moot questions from one having the same background and fundamental training as ourselves. There is confidence in the methods of observation and the processes of deduction—a feeling that various factors have been properly evaluated so that the final conclusions are comparable to those which we ourselves would have reached under similar circumstances and with similar opportunities.

A significant fact in the outcome of Mr. NEGRU'S trip is that while he set out hopeful of obtaining much in the way of new technical information, of research, of new and improved products and processes, the field proved so barren in this respect as to have yielded little or no fruit. On the contrary, he found European industry so deeply involved in economic distress as to lead him almost to abandon the search for technical matters and turn his attention to the business and financial situation as it affects personnel, processes and

products in the chemical and related industries in Europe, and incidentally in this country. This aspect, then, will characterize the articles which we hope will prove helpful in getting a correct view of European conditions.

Recognizing a Community of Interest

SOME waning of interest in the Chemical Warfare Service is becoming manifest even within the chemical industry itself. Just as those who live behind levees are inclined to forget about floods when the river is low and neglect protective measures, so it is, observers in Washington point out, with the work of the Chemical Warfare Service in peace time. It is thoroughly understood that such a tendency is the natural one. It applies to all branches of the military service. The Ordnance Department, for instance, is having the greatest difficulty to induce manufacturers to co-operate in the design of their materiel so that equipment may be planned that offers the minimum of manufacturing difficulties.

As to the Chemical Warfare Service, however, there is a feeling that the chemical industry should be careful to keep alive its co-operation and to maintain all its contacts with the organization. This is regarded as imperative, since the Chemical Warfare Service has not been thoroughly "sold" to the American public. More than that, the industry is under particular obligations to the Chemical Warfare Service, since its officers boldly took a course in defense of the dye embargo which was known to be unpopular with a majority of the members of Congress—the body to which the Chemical Warfare Service must look for its funds and for its very existence. In view of that disregard of its own selfish interest, there is a feeling that the chemical industry should be unusually observing in keeping alive its co-operation with the Chemical Warfare Service in an effort to solve its problems.

Chemical Imports And Reparations

PERSISTENT reports by the newspapers that chemicals would be accepted on the reparations account have caused a stir which now appears to have been wholly unjustified by the real facts in the situation. Nevertheless this bogey will doubtless bob up again at intervals as some enterprising newspaper man runs onto a new angle or a new possibility of the story. It is worth while, therefore, to have clearly in mind a few of the facts involved.

The State Department has unquestionably been considering the proposal that the government be paid for the expense of maintaining the American army of occupation in Germany by means of imported dyes and chemicals. The amount due the United States is approximately $250,000,000. If that debt be regarded as interest-bearing and 4 per cent be assumed as a cost of money to the government, then $10,000,000 per year will have to be paid on account simply to keep up the interest. To make any appreciable inroads on the principal would require several times that sum annually.

In the past, import of dyes and chemicals through the Textile Alliance was made without direct participation of the government. The government simply sanctioned the proceedings and handled none of the money or commodity. The new proposal would necessitate either money or commodity or both being handled by the government at some stage of the proceeding. There is at first sight no legal ground for entry of the government upon such a proceeding without specific additional approval through new legislation by Congress. Furthermore, to permit such import would be contrary to the entire spirit of a protective tariff policy. Therefore, if Congress should be asked and should grant permission for establishing such an importing agency, it doubtless would be limited to one that could bring into the United States such dyes or chemicals as would not compete with domestic products. But if one limits the import to non-competitive commodities, then the quantities involved would be small. Estimates as to how small they would be vary considerably, but no one seems to feel that the amount would be greater than three or four million dollars per year and, what is more probable, only about one million dollars per year.

Considering these figures, it is evident that no material progress can be made in payment of reparation accounts by the import of chemicals unless an entire change in our foreign trade policy is adopted by Congress, or by the State Department without the consent of Congress. In view of these facts, there is certainly nothing alarming about the rumors even though they seem to have very credible source and backing.

We should not lose sight of the fact that the appointing of an import agency might establish precedent for the importation of other commodities than dyes and fine synthetic organic chemicals. There is no doubt that this country will eventually have to take its payment for the expenses of the army of occupation in commodities, for it is not conceivable that we would be granted any cash payment while other reparation accounts for Belgium, France and other European countries remain unpaid. There will be great temptation therefore, for legislative and administrative officials who desire to make a good financial showing for government affairs to look forward to some arrangement for the regulated import from Germany of commodities the sale price of which can be credited to the United States Government instead of going to the German exporter. This is a tendency and a possibility which deserve careful study. That there is likely to be any such development seems improbable, but in forecasting future developments it is worth while to consider even so remote a contingency as this.

Making Use of Facts and Figures

BUSINESS judgment in the long run can be no better than the information on which it is based. This simple truth is the real evidence on which that very practical scientist HENRY S. DENNISON is willing to rest the case of "Facts and Figures" vs. "Hump and Hunch." In a talk last week before the National Conference of Business Paper Editors he gave it as his opinion that many of the hard-headed old fellows who have opposed the scientific management of industry and the use of facts and figures really carry around just this sort of data with them and don't know it. Their "hunches" are based, in a sort of subconscious way, on sound knowledge and ripe experience tucked away somewhere in the backs of their heads. Charts and graphs, they say, will eliminate judgment and make business merely the Punch-and-Judy show of automatons. On the contrary Mr. DENNISON avers that these facts and figures are

sponsible for the most exacting demands on judgment. is when a man is in possession of all the facts in a se that he is most likely to ponder the consequences his decision.

Take, for instance, the problem of facilities. How do ou know when to order machinery, or additional equipent, or a new building? Right now you may be badly need of one of these things, but how about six months a year from now when the piece is installed or the uilding completed? Here it is that the executive with finite knowledge of his business, of its normal line of rowth and of the records of the past and present inustrial situation can gage his purchase with precision nd foresight.

The past is our only yardstick for measuring the uture, and it can be put to work in no more useful way an in helping to solve the problems of buying and elling. The long-time price curve of a commodity lotted along with warehouse stocks is a most reliable uide to the buyer. He needs but to establish some iedian line of "normalcy" and when prices are above hat line to buy relatively less, when prices are below he median line to buy relatively more. Such a policy onsistently pursued must mean a dollars-and-cents savng to the buyer. Furthermore, it relieves him of that rain which accompanies the frantic endeavor to find he exact bottom of the market or, what is more comorting, he avoids the disastrous tumble from the top.

Business, because it is such a multifarious thing, can ever be charted with the certainty and fairness of an ngineering project. There will always remain breaches nd gaps which will not be bridged by facts and figures. abor policies, employee selection, promotion, etc., are stances in which we must always lean heavily on huan judgment and appraisal. But even if our data are ragmentary and incomplete, it is no reason why we hould not use what we have to best advantage. The hysician knows but a surprisingly small fraction of the ndamental facts of health and disease, yet it is on he judicious utilization of these facts that the medical rofession has made its remarkable progress. The govrnment, the trade associations and other agencies are t work gathering data, the completeness of which will epend in the last analysis on whether or not it is put practical use. Are you, as an individual, making the ost use of the facts and figures of your business? f not, you are the loser.

The Coal Users' Part

T WILL not be coal production but rather coal transportation that will limit fuel supply during the comng winter. It is almost certain, even with an open inter, that there will be distressing shortages at some oints and if we have a severe winter the shortage will e very serious in many localities. Anything that the al user can do to relieve this situation even slightly s a duty to the community as well as to himself.

One very obvious but often neglected responsibility f this sort is the prompt loading and unloading of cars. ot alone coal cars but cars of all types must be moved s expeditiously as possible if the railway systems of he country are to function even fairly well this winter. t behooves the chemical industries which are large sers of freight cars to make adequate preparation for eir part in this work. When a car is placed for loading, it should be filled at once and billed by the most direct route to destination. When a loaded car arrives at a siding, it must be unloaded immediately. No excuses should be permitted to interfere with this part of rail traffic handling.

The difference between immediate and only "fair" handling of this situation may make the difference between adequate and inadequate fuel supply. The price which one may pay in current inconvenience or bonus for overtime in order to accomplish these results will be a splendid investment. It will pay to get ready now and not wait until bad weather or traffic congestion makes the problem even more serious than it already is.

From One High Position to Another

IT IS with mingled feelings of pleasure and regret that we receive the announcement that Dr. S. W. STRATTON is to leave the Bureau of Standards to assume the presidency of Massachusetts Institute of Technology. The change will represent a great loss for the bureau. That institution will for many years stand as a monument to the vision and constructive ability of the man who has been its chief from the beginning until now when, twenty-one years old, it stands a mature evidence of well-nurtured growth.

Nor is there doubt that M.I.T. should receive our congratulations. It is an institution in which any man may find large opportunity for service and for constructive effort and hence to Dr. STRATTON also go our congratulations on the opportunity in this new field which that institution will afford.

May his work there prove as successful as has his public service in the Bureau of Standards. One could scarcely wish him greater success than that.

Any Size Is Standard

INQUIRY was made at the booth of one of the exhibitors at the recent Chemical Exposition for a catalog of stock sizes and shapes. The answer to the query was that any size or shape desired is gladly made for customers and that no standard sizes of the material were listed or carried in stock. This represents for the particular industry rather an unfortunate situation, and yet one all too common at present in many lines of business.

In this particular case, each new size or shape requires new dies or new tools. Yet the company stands ready to deliver any size as standard. It would be interesting to know how much this really costs the purchasers of the material, for certainly it would be vastly more economical if a reasonable number of standards were maintained and effort made to limit purchasers to these as far as their needs really could be served thereby. The saving might be a substantial sum in dollars per year and probably an appreciable percentage of the cost of any shipment of special sizes.

In a vast majority of cases there is considerable latitude in choice of sizes for such materials as the one in question. A designer is perfectly willing to vary a few hundredths of an inch, and if given adequate data will find it quite as convenient to design his equipment to use the sizes which the maker carries regularly in stock as a standard. It is surprising in this modern day of efficient management to find that a prominent concern apparently ignores the advantages of simplification in production. Doubtless there are many others. All should stop and consider the folly of the policy.

Readers' Views and Comments

Black Fractures in Carbon Tool Steel

To the Editor of Chemical & Metallurgical Engineering

SIR:—We have recently had opportunity of examining a small piece of steel, sent us by Mr. Green and described by him in your columns for Aug. 9 (p. 265). Some comments written primarily from the standpoint of men working with malleable cast iron may be of value.

Under the microscope the graphite in the piece sent us is present in thin flakes and not nearly as much spheroidized as is the temper carbon of malleable casting. I have never in the past seen such a flaky condition in any graphite which was precipitated below about 1,050 or 1,100 deg. C. There is here some suggestion that the observed graphite came out early in the history of the specimen, yet the fact that the graphite does not exist in the surrounding ring is scarcely consistent with the precipitation of graphite in the ingot before rolling. May we suppose that the ingot was graphitic and that the pressure exerted by the rolls assisted the recombination of graphite, due to the contraction in volume assaociated with the formation of cementite, as suggested by Heike? If this assumption is not tenable, then it would seem that the only possible explanation is that such stresses are set up in the surface layers during rolling which have prevented graphitization during the anealing period. There is here another anomaly.

It is well known that even in the high-silicon, high-carbon alloys of the malleable cast iron industry graphitization is a matter of many hours. The times may run from 40 to 80 hours above 1,500 deg. F., followed by at least an equal time in cooling. How graphite should form in but slightly hypereutectoid steels in a time as short as is involved in the annealing of tool steels has always been a mystery to me. I have frequently heard the experience mentioned, but Mr. Green's sample is the first which I have personally seen.

H. A. SCHWARTZ,
Manager of Research,
The National Malleable Castings Co.

Cleveland, Ohio.

The Record of Science

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have just read with considerable interest and enthusiasm the address of William Warner Bishop before the Michigan Chapter of Sigma Xi on "The Record of Science." There is one very significant statement in this address: "Bibliography is the foundation of research." Mr. Bishop gives a very clear brief for his premise, and the case could not be argued by a single man better equipped to argue the case.

Mr. Bishop further shows that we are placing too much stress on the laboratory side of research and not enough on the fact side.

Facts support Mr. Bishop in his assertion. In the second edition of the National Research Council's "Research Laboratories in Industrial Establishments of the United States" we find over 526 organizations supporting research laboratories. In *Science* for Jan. 13, 192[illegible] on page 51 we find that there is invested in this countr[illegible] alone 565 funds for research, yielding annually ove[illegible] $22,000,000. Yet I venture to assert that not 50 pe[illegible] cent of these same institutions provide adequate fund[illegible] if any at all, for a good foundation in research—namely, what I choose to call " laboratories for researc[illegible] fact-oring"; to put it in Mr. Bishop's phraseology[illegible] laboratories in the "book sciences." To illustrate th[illegible] relative importance given to the laboratory for ordinar[illegible] research and the laboratory for fact research, or library[illegible] I know of one industrial firm that invested over $400,00[illegible] for research laboratories, and yet the sum invested i[illegible] book equipment was less than one-tenth of that amount[illegible]

Why not establish endowments for laboratories i[illegible] research fact-oring and fellowships in the "boo[illegible] sciences?" The need is here and should be met.

Pittsburgh, Pa. K. WALKER.

A New Vessel for the Absorption of Hydrochloric Acid

To the Editor of Chemical & Metallurgical Engineerin[illegible]

SIR:—I note in "Readers' Views and Comments" i[illegible] your Aug. 23 issue M. A. Laury of Rockville Center L. I., has misunderstood a statement in my article whic[illegible] appeared in your Aug. 2 issue, and I am writing you t[illegible] clear up this point in case other readers have give[illegible] it the same interpretation.

My statement to the effect that it was only possibl[illegible] to produce acids of low strength from towers was in[illegible] tended to convey the idea that only low-strength aci[illegible] can be produced if the absorbent is permitted to flo[illegible] through the tower absorption system by gravity onl[illegible] and is not recirculated and applies more especially t[illegible] the gases of higher strength than those of lowe[illegible] strength.

The point which I intended to bring out was tha[illegible] in order to obtain acids of higher strength by singl[illegible] exposure of the absorbent to the gases it is neces[illegible] sary to use absorption equipment which will permi[illegible] rapid removal of the heat generated and that the con[illegible] struction of a tower to accomplish this is not, in genera[illegible] practicable.

Acid of much higher strength than 20 deg. Bé. ha[illegible] been obtained from towers, but only by cooling the aci[illegible] produced in the tower and recirculating this throug[illegible] the tower repeatedly until the strength is increase[illegible] to the desired point. STEPHEN L. TYLER.

New York City.

Correction

In one of the "Sidelights on the Chemical Exposition[illegible] appearing in the Sept. 27 issue, the "Dow" tray thick[illegible] ener was mentioned as having been applied to th[illegible] clarification of raw cane juice by the firm of "Petree[illegible] Dow." This of course should have been called the Do[illegible] tray thickener and the firm is Petree & Dorr.

Mechanical Improvements vs. Fundamental Research in the Leather Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of Aug. 30 (page 465) you publish an article from the versatile pen of John Arthur Wilson, entitled "Mechanical Improvements vs. Fundamental Research in the Leather Industry." The writer has made an exhaustive study of the mechanical end of the leather business and while he agrees thoroughly with Mr. Wilson that opportunities for increased production efficiency lie less in mechanical improvements than in fundamental research, he feels bound to impress on the tanner that 6 months' tanning of sole leather is not only an unnecessary waste of time and money invested, but almost a commercial crime for which all users of leather have to pay.

The fundamental chemical research under Professor Thomas of Columbia and that of Mr. Wilson have been of inestimable value to the tanning industry, and they have gone far toward a campaign of industry to show the tanner what the possibilities—yes, certainties—of chemistry can accomplish, yet I feel sure that neither of these accomplished men would agree with me that sole leather can be tanned in 5 or 6 days with but one handling, producing fine, light-colored, plump, smooth grain leather of great toughness. The apparatus that produces this result is very simple of construction and "foolproof" in operation.

I am not writing this to draw attention to my patents or to describe in detail the apparatus that is in daily operation at our laboratories, but simply to give my views as to why the tanners do not abandon the antiquated and senseless method of tanning they now pursue.

It has been my experience that tanners, as a rule, are too slow and even unwilling to adopt what seems to them a revolutionary process of tannage, but it must be known that the two largest producers of sole leather are now tanning a part of their product in less than a week's time and are fast approaching complete installation of rapid tanning machines.

I want to assure Mr. Wilson that while it is true that the rate of tanning, the rate of penetration of tan liquor into a hide, the degree of plumpness of the leather and its color and smoothness are all controllable chemically, it is just as true, and more understandable, when leather is tanned in a machine where every individual hide gets the same treatment in 5 or 6 days.

The great drawback to the English Wilson machine lies in the fact that the sides, as they come from the trenches, are in a very tender state and will not withstand constant falling and folding as they revolve in the machine, as such flexing produces tan wrinkles and raised grain. Sole leather, to be properly tanned and plumped, should have practically no movement that will bend or wrinkle the hides.

The writer spent two long years in developing apparatus that would automatically tan 144 sides in a machine having 1 minute periods of immersion and emersion, permitting the hides to slip gently into the tanning liquor and to float through the same in a natural position, emerging from the liquor without sharp bending or unfolding. As before stated, we are able to get the best results in 5 and 6 days.

While the industry needs the most highly trained chemists available, it also needs men who will accept facts as against theory, and who will awake to the fact that "layaways" should be obsolete and that a vast amount of money can be saved to the industry if tanners will develop a spirit of investigation and acquaint themselves with development that may be theirs for the asking.

The Chemical Industry and Its Exposition

To the Editor of Chemical & Metallurgical Engineering

SIR:—It is reassuring to find in *Chemical & Metallurgical Engineering* the admission that criticism—adverse criticism—of the Chemical Exposition as now conducted does exist and is finding expression in several quarters. As noted in your editorial, this criticism has been diverse and confusing; but out of all the clamor and discussion one point stands out clearly—namely, that the management needs closer contact with the exhibitors.

It is admitted quite generally that the producers of our chemicals, chemical equipment and raw materials, as well as the chemists, engineers, plant managers and salesmen, were not in sufficiently close touch with the management to make an entire success of this national exposition.

Hence has arisen the need for a new enterprise, a Chemical Industries Exposition managed by the industries themselves, such as is now proposed. By its name, the Chemical Industries Exposition, the new organization is pledged to serve the interests of chemistry. It promises to show what industries chemistry has built up and how chemistry works in those industries.

Our first chemical show was a brave attempt to fulfill such a promise. The time was propitious and the show was considered a success, while the expositions that succeeded the initial show were also considered successes; but now that the novelty has worn off and we can scrutinize conditions more closely we find that a true exposition of our chemical industries has never been held, what we have had being only a heterogeneous mixture with an overwhelming number of exhibits that would fit in a machinery show or a show by any other name as well as in a chemical show.

A true exposition of our chemical industries is as necessary today as it was in 1915. To borrow the language of the salesman, it is the ideal way of "selling" the chemical industries to the country at large. It should be the ideal way of demonstrating that in our chemical industries lies the possibility of our greatest industrial development.

This is what is proposed by the new Chemical Industries Exposition, which will be a purely co-operative organization for the advancement of our American chemical industry. An exposition under the management of professional showmen such as we have had in recent years cannot be considered representative, neither can it be arranged as an exclusive, orderly and well-balanced exposition of the chemical industries as was originally intended and as is now proposed.

In view of the foregoing it is hoped that *Chemical & Metallurgical Engineering* will yet see its way clear to support the new enterprise.

To Study Fuel Economy in District of Columbia

At the request of the director of the budget, the Bureau of Mines is conducting a fuel economy survey to investigate the conditions under which fuel is used in the various government fuel-using plants in the District of Columbia, and to determine what economies, if any, can be made in the use of such fuel.

European Conditions as I Saw Them

Epitome of Six Months' Study in Germany, Belgium, France, Switzerland and Italy—Failure of Germany's Economic War the Fundamental Cause of Present Financial Collapse and Its Effect on Other Nations

By J. S. Negru

Editor's Note: Mr. Negru, managing editor of *Chem. & Met.*, has just returned from a 6 months' trip to Europe, where he studied the industrial, technical and economic conditions in the principal countries of the Continent. This article is the first of a series that will portray intimately the results of his interviews with financial, political and industrial leaders. Other articles will deal with detailed observations on which this summary is based.

A SIX months' trip through Belgium, France, Italy, Switzerland and Germany for the purpose of getting first-hand information and impressions on the technical and economic status of those countries may seem at first sight a simple and agreeable undertaking. As a matter of fact, it proved to be a very trying task when it came to the actual performance. Although many circumstances and conditions were anticipated and taken into consideration well in advance, many more unforeseen circumstances were encountered during the trip which sometimes made it necessary to alter quite radically the plans laid down while still in New York City.

Plans of Trip as Outlined and as Carried Out

It was quite easy to outline a plan covering places to visit, persons to see and subjects to study. In fact, this was done to a nicety. The places to visit were those generally regarded as the leading industrial regions of the above-mentioned countries. The persons to see were obviously the leaders in the industries, the presidents and secretaries of the leading technical societies, the editors of the well-known technical papers for the different industries covered by the thirteen McGraw-Hill engineering and industrial papers, with special attention to those covered by *Chemical & Metallurgical Engineering*. Incidentally, there were other important sources of information—economists, labor leaders and just plain folks. The subjects to be studied were mainly the actual technical progress during the last few years, scientific research, the economic conditions as to production, and relations between employer and employee. Incidentally, I was to get some ideas on everyday working conditions with respect to machinery, apparatus and processes in European plants compared with those in the United States.

A schedule covering this broad program was carefully made out, advance information was sent abroad regarding my contemplated trip and its purpose and the anticipated trend of events and interviews were sketched out as fully as possible. With plans thus matured and with a deep feeling of the importance of the trip to the readers and advertisers of *Chem. & Met.* and other McGraw-Hill publications I embarked on the good ship Finland sailing from New York Feb. 11 and arrived in Antwerp Feb. 22.

In the interim of the past 6 months I have visited the places scheduled and many more; I have interviewed the persons originally selected and many more of equal importance. But unforeseen conditions arose when it came to the subjects to be studied. The economic status of the countries visited was so abnormal and so differently interpreted by interested parties that I was led to dwell far more in detail on this part of the program than on anything else.

My first intention was to edit my notes in chronological sequence, but the present upheaval in all the industrial countries of Europe, particularly in Germany, leads me to believe that it were more timely first to outline what I regard as the very fundamental cause of the breakdown in Germany, with the result that all of the other countries are feeling acutely the repercussion of such an unhealthy economic condition.

Obedient Germans

The German possesses as a general rule a highly developed obedient mind, and few are those who, being sufficiently emancipated, dare assert their individuality. The German Government created during the so-called revolution shortly before the armistice is a sort of emergency organization like the receiver of a bankrupt business concern, with a beautifully written constitution as a guide, but with no self-asserting leaders, and hence extremely weak.

To this very day practically the entire German people are still lulled with the belief that Germany, more than any other belligerent country in the World War, acted as a civilized nation, and do not yet know the extent of the wanton destruction engineered by their military and industrial leaders in the occupied French, Belgian and other allied countries. The Germans, as I have learned to see them, consider themselves persecuted for no reason whatever. They were not given to understand that they must make good, partly at least, what they call incidental war destruction. They were fed from the beginning, and still are fed, with an abnormal hate toward France, and more recently with an even more abnormal so-called friendship toward England. Thus they have been led to the point where they typify to the very letter the cartoon "Vox Populi" printed in the June 2, 1922, issue of *Fliegende Blätter*, which is here reproduced.

The German Economic War

With a weak government on one side and a meek people on the other, it will be seen how very easy it was for wolves in sheep's clothing to bring about what really happened—namely, to involve Germany in a disastrous war before, so to speak, the ink was yet dry on the signature of the Versailles treaty.

Many are the interpretations of the causes leading to the present pitiful condition in Germany, but all of them seem to be attempts to place the blame on the other fellow and not in the least on the Germans themselves. The Versailles treaty stipulations are being represented as demanding far more than Germany can fulfill. All such interpretations by bankers and others are, to my judgment, dictated strictly by egoistic business considerations. But when analyzed in the light of many conversations I had with leading German intellectuals and plain people in many German districts, the break-

From *Fliegende Blatter*, June 2, 1922.

VOX POPULI

down seems to be a normal consequence of losing the economic war which she has been waging against all the world for nearly the past 3 years.

Briefly stated, the specific plan of this economic war was to flood all foreign countries with German finished products, especially those requiring a large amount of manual labor, at prices far below their intrinsic value. It was to be a super-dumping policy in the expectation of spreading unemployment in other industrial countries, thus creating an atmosphere and undercurrent of opposition to the Versailles treaty, and offering as a condition of truce the cancellation of that treaty and a status quo ante bellum 1914.

Such an economic war was conceived by a few Germans of the Stinnes type as the best means of evading the fulfillment of the conditions of the peace treaty. This was not because Germany could not fulfill them, but because primarily the German honor must be saved. And the worst that could happen to tarnish the good name of Germany, according to their peculiar psychology, would be to submit to the treaty stipulations. They were not able to bring themselves to act as good losers.

Failure of Germany in Its Economic War

When the German soldiers returned to their homes after the war, they were treated as unconquered *Helden* and still are considered as such. They found their houses, fields and factories open, in full prosperity and ready to engage them in productive work. It is well known that the Germans are very industrious. Before 1914 the intrinsic value of domestic production in Germany was many thousands of millions of gold marks per annum. The more so could have this been the case after the war if the new government and the masses had not been led astray by the then few powerful Germans who thought to evade the stipulations of the Versailles treaty by means of an economic war. How very simple such a war looked to them is proved by the readiness with which it was approved and carried on. That it was hastily conceived and badly fought is proved by the dire distress now confronting the German Government and the German people in a Germany which is still eminently rich.

The German mark, which in 1918 was worth 25 cents, has recently been quoted at a little less than 0.05 cent, and everything points to its further decline. And yet Germany is working at full capacity in all her industrial lines, the German people are among the most industrious in the world and German agriculture is sufficient to supply at least 70 per cent of the people's food requirements.

As in their conceited war policy of imposing peace negotiations by methods of frightfulness, so in the present economic war they hoped to reach their goal without counting on the psychology of the other nations. They expected that the foreign buyers of their products, who would purchase them at far below their intrinsic value, would content themselves with, say, a maximum of 100 per cent profit. But they did not count on the rapacity of the newly arisen middlemen who, not content with such profit, succeeded in placing in foreign countries the cheaply bought German wares at prices a trifle below those of similar domestic products. This fulfilled only part of the German aim—namely, the spreading of temporary unemployment. But it was done at the cost of breaking down the German fighting power by bringing the government near to the point of fraudulent bankruptcy, and this in spite of the fact that the tonnage of products exported and their true intrinsic value are so very high. Neither the total amount of gold marks

which Germany has paid to the Allies up to date nor the status of the Saar district and Upper Silesia warrants the bankruptcy of a country which only about 4 years ago regarded itself as the very leader among the world's nations and rattled the saber in an attempt to make everybody else admit it.

Germany Can Regain Her Place in the Community of Nations

The gradual losing of their economic war and not the hair-splitting notes to and from the Allies and the various conferences is the cause of the German breakdown. Fortunately this could be easily mended if only the German people could be brought to realize that just as in 1918 their armies did not return to their homes as unconquered *Helden*, so now their economic war is lost forever. Honest work with honest competition, coupled with a sincere resolution gradually to fulfill Germany's signed promises at Versailles, must be henceforth their guiding policy if they are to regain their new place in the community of nations.

The next of this series of articles will be published in the issue of Oct. 25, 1922.

Electrosmosis and Electrophoresis, Two Definitions*

By Oliver C. Ralston
Department of Interior, Bureau of Mines, Berkeley, Calif.

THE purpose of this note is to call attention to an exasperating confusion of terms in the literature that deals with electro-capillary phenomena, the electric double layer at phase boundaries and in colloid chemistry. The four following words should cover all general cases where an electric current is passed through a fluid medium, with or without a diaphragm, with or without the presence of other solid, liquid, or gaseous particles other than the electrodes or on the electrodes:

Electrolysis.	Electrophoresis.
Electrosmosis.	Electrostenolysis.

Nearly all the roots used in these words are of Greek origin. Electrolysis, for instance, is divided into electro and lysis from roots meaning "by means of electricity" and "loosening, dissolution or destruction" respectively. It is therefore well to consider first the meanings of portions of a few words.

Cath-	down or away.	Endos-	within.
-ode	way or path.	-mosis	push or impulse.
An-	up or toward.	Cata-	down or away.
-ode	way or path.	-phoresis	bearing or carrying.
Os-	mouth or pore (Latin).	-sis	suffix meaning process or state.
-mosis	push or impulse.	-osis	suffix meaning process or state.

With these few roots and their meanings it is now possible to discuss the above four words, which are proposed in the interest of obtaining uniform nomenclature, with a minimum of change from present practice and without inventing completely new words.

Object of Words Proposed

Electrolysis is a term universally accepted as meaning the act or process of chemical decomposition by means of the electric current.

Electrosmosis is proposed by the writer to supplant such terms as electric osmose, electrical endosmose, electric endosmosis, electro-osmosis, etc. All of these terms mean the passage of liquids through diaphragms (osmosis), due to the application of electrical forces. They are all in use, but all are somewhat awkward when used otherwise than as nouns. If the noun "electrosmosis" is adopted, it can be modified to the verb "electrosmoze" to correspond to the verb "electrolyze."

Electrophoresis is proposed to supplant a number of words that have been sadly misapplied but whose use has almost become correct through common (mis)usage. By electrophoresis is meant the travel, transport or "wandering" of a particle of solid, liquid or gaseous matter suspended in a mobile medium, liquid or gaseous, when a unidirectional electric stress is applied. At the present time "cataphoresis" is the word usually heard in this connotation, although "electrophoresis" has been used by a few discriminating writers.

The objection to the use of the word "cataphoresis" is that most of the particles suspended in aqueous solutions are negatively charged and migrate toward the anode, whereas the prefix "cata" or "cath" is already associated with "cathode" and "catholyte." A few writers have therefore tried to apply "cataphoresis" only in cases where particles wander toward the cathode, and have invented "anaphoresis" to apply to the usual case of wandering toward the anode. They were the ones who invented "electrophoresis" as the general phenomenon. Due to the wide use of "cataphoresis" it would seem unwise to try to force its use for a case of "electrophoresis" in which the particle wanders toward the cathode, a direction which is just the opposite of 90 per cent of the cases of so-called cataphoresis. Rather it seems wiser to adopt a term somewhat different in spelling, enough different to force recognition of the true meaning, and yet not enough different to need definition. Therefore:

Cathodophoresis is proposed to mean migration of suspended particles toward the cathode when under the influence of a unidirectional current.

Anodophoresis is proposed to mean migration to the anode.

Usefulness of the Term "Electrophoresis"

A further discussion of the possibilities of the use of the term "electrophoresis," as defined above, will show its great usefulness. It need not apply alone to colloidal solutions, but it can also apply to smokes, mists and fumes. The Cottrell electrical precipitation process has long lacked a single word to describe correctly its prenomena. It is permissible to speak of "electrophorizing" these suspensions of solid or liquid particles in gases. We can also "electrophorize" emulsions of water in crude petroleum, a process which has long wanted a name and is now in such large-scale use that a less accurate name is likely to be attached to it if we do not act to embody properly these ideas in suitable words.

Electrostenolysis is a term used to designate the deposition of certain metals in small capillary pores of certain diaphragms when solutions of these metals are electrolyzed. This is a rather obscure phenomenon, but its name is fortunately quite correctly derived and used. However, the definition should not be restricted to the deposition of metals in pores of diaphragms, as someone may discover methods of depositing other elements or groups in like manner.

*Paper presented at the forty-second general meeting of the American Electrochemical Society in Montreal, Sept. 21, 22 and 23, 1922.

Handling the Finished Products of Industry—VI

The Handling Problem in Sugar Manufacture Consists of Packing and Shipping a Single Finished Product in Many Ways—Solution of This Problem Illustrated by the Layout of the Baltimore Refinery of the American Sugar Refining Company*

By Graham L. Montgomery

ONE of the most difficult problems met with in handling finished products is that condition where a large bulk of product is to be packed in many packages and shipped in several ways. This type of problem is one encountered particularly in the sugar refinery.

Because of this difficulty, many plants of this type have never attempted the installation of a real handling system. Others have placed as much handling equipment as could well be worked in with their existing layouts, but have not been able to make their system a unified whole. This particular industry has been one where it has been necessary to wait for the construction of a real up-to-date plant in order to find the possibilities which lay in handling the finished sugar completely by automatic equipment.

Keeping these two facts of diversity of package and diversity of shipping-means in mind, together with the additional fact of large total output, let us consider the new refinery at Baltimore recently placed in operation by the American Sugar Refining Company. This plant is the most modern in the country. In designing it, the American Sugar Refining Company pooled the best of its knowledge and experience—forming a consulting board, made up of expert sugar men, refinery operating engineers, construction engineers and others, which worked out for the Baltimore plant a comprehensive handling method, one which provides ample opportunity for expansion when that becomes necessary.

The product is placed in every conceivable type of wholesale and retail package, and is shipped by all available means over a wide territory.

Where the Finished Product Handling Occurs

For the purpose of the study of the handling system used here, a good starting point can be made at the place where the granulated sugar leaves the screens which separate the coarse sugar and the dust from the commercial grade. There is, in the case of powdered sugar, one further manufacturing process—that where the granulated sugar goes through pulverizing mills. With this exception, all operations beyond the screen consist of handling and packing operations. These operations do not increase production or add to the quality of the product, but they are necessitated by the exigencies of marketing and involve what we classed as non-productive labor in the first article of this series.

This would hold for any sugar refinery. The Baltimore refinery here described illustrates the nearest approach to perfection that has been obtained in this work, the nearest approach to elimination of non-productive labor that seems at the present time possible; and the rendering of as many operations as can be automatic.

As a basis of study of the handling system, the following tabulation is given for methods of packing and types of shipping:

Packing

1. Granulated sugar packed in bulk barrels.
2. Granulated sugar packed in bulk sacks.
3. Powdered sugar packed in bulk barrels.
4. Granulated sugar packed in cotton bags.
5. Granulated sugar packed in paper cartons.
6. Powder sugar packed in paper cartons.

Shipping

1. Local shipment by gasoline or electric trucks.
2. Water shipments on lighters to ships or to piers.
3. Railroad shipment in box cars.

General Handling Considerations

From the screens, the desired grade of sugar may take two paths. Immediately below the screens are large maple-lined concrete bins to which the sugar may be fed directly by spout. These bins serve to supply the sugar for filling bulk barrels and sacks, the filling of these containers taking place immediately under the bins. They also serve as a storage reservoir to take sugar from the manufacturing department when the packing department is not working, and to keep the packing department supplied should the manufacturing department shut down for any reason.

When these bins are filled with sufficient sugar for loading the bulk barrels and sacks, the sugar is led from the screen by spouts on to a trough belt conveyor. This conveyor discharges into a vertical spout, which delivers the sugar in one of two ways. First, to the conveyor which supplies the packing department for paper cartons and cotton sacks, and second, to the conveyor system which feeds the powdered sugar department.

Packing Bulk Sugar in Barrels

Before describing the methods used for filling barrels with bulk sugar, it is of interest to consider how the barrels are handled from the cooperage.

The cooperage is housed in a building 465 feet away from the point where the barrels are to be filled. In this cooperage the lumber from which the barrels are constructed is received from the company's own lumber mills in cars and made up into the barrels—the heads being made separately and delivered to the packing department in the same quantity as the barrels.

It is interesting to note in passing that the American Sugar Refining Company owns its own forests, does its own lumbering, has stave and lumber mills, owns various railroads, due to this lumber work, which are even equipped in some cases to carry passengers—in fact, owns many similar adjuncts which make it practically independent of others for the necessary accessories, such as cartons and barrels.

The conveyor which carries the barrels from the cooperage to the packing building is particularly worthy of note. It is made up of two chains running parallel, just as in the ordinary slat conveyor; but, in place of

*Previous articles in this series have appeared in *Chem. & Met.* as follows: Article I, vol. 26, No. 18, p. 823, May 3, 1922; Article II, vol. 26, No. 19, p. 885, May 10, 1922; Article III, vol. 26, No. 24, p. 1,114, June 14, 1922; Article IV, vol. 27, No. 5, p. 199, Aug. 2, 1922; Article V, vol. 27, No. 15, p. 731, Oct. 11, 1922.

slats, ball-bearing rollers are used. The barrels ride forward on these rollers just as they would on a slat conveyor. But if the conveyor load is stopped for any reason, the conveyor continues on underneath the load without any particular amount of friction because of the ball-bearing rollers

This type of conveyor is particularly adapted to just such operations as filling or packing. It permits the production of barrels to go on at the cooperage regardless of the rate at which the barrels are filled, the long conveyor acting as a storage if filling is held up for any reason. There are many other cases where the operation at the loading end of the conveyor must run at a different speed from the operations at the discharge end. For this type of service, the conveyor described above, which is called a driven-roller conveyor, is in many cases ideal.

Handling Empty Barrels in the Packing Building

This straight run of conveyor from the cooperage enters the floor of the packing building on which barrels are packed at a point near the ceiling, and delivers through a gravity roller spiral to a second driven-roller conveyor, which runs the length of the barrel-loading dock and at the same level. By means of this conveying arrangement, a constant supply of empty barrels is kept handy at the loading dock. Reference to Fig. 1 shows the approximate arrangement of this system.

The workers who are doing the barrel filling take the barrels as needed fromthe last conveyor and after lining with paper place them on shakers under the filling spouts which lead from the large concrete bin previously mentioned. These shakers, by keeping the barrel agitated while it is being filled, insure its full loading.

Handling Filled Barrels

After the barrel is filled, it is rolled off of the shaker on the opposite side from the empty barrel conveyor and the head is placed in position. On this side of the barrel loading dock is another driven-roller conveyor similar to the others described. This conveys the filled barrels to the scale, where their weight is noted. So that the scale operator may have absolute control of the rate at which barrels pass over his scale, a pneumatic device has been installed at the end of the driven-roller conveyor, which causes the barrels to pile up here until wanted. By means of this penumatic device,

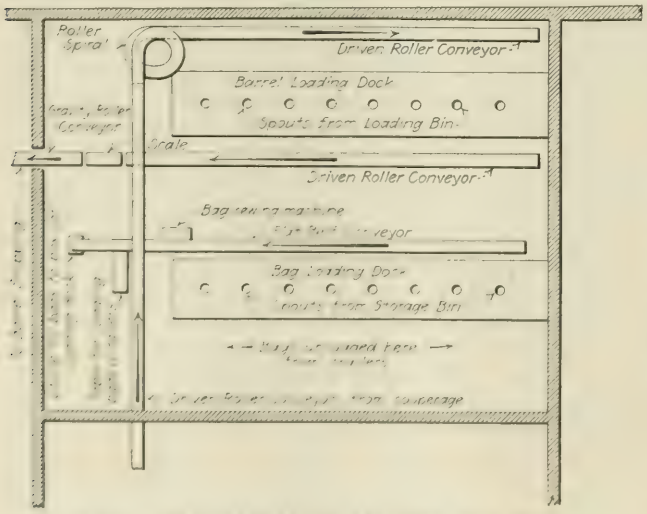

FIG. 1—DIAGRAMMATIC LAYOUT FOR BULK PACKING DEPARTMENT

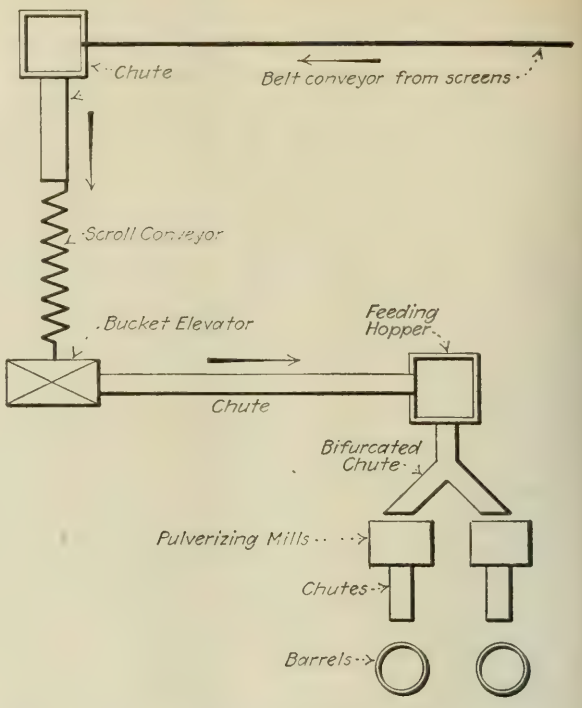

FIG. 2—DIAGRAMMATIC LAYOUT OF POWDERED SUGAR DEPARTMENT

he can release them one at a time onto the gravity conveyor which carries them over the scale. After their weight is noted, the barrels continue on this gravity roller conveyor, which discharges them on a loading dock, where they may be either loaded onto trailers or onto the barrel elevator and distributed as described under the heading of shipping.

Loading Bulk Sugar in Bags

Fig. 1 also shows the layout of the loading system for bags of bulk sugar. The routine is as follows: The empty bags are brought to the bag-loading dock on trailers. The workers place them as needed under spouts coming from the large concrete storage bins. Each of these spouts is provided with a weighing hopper, so that each sack receives a definitely weighed amount of sugar. After filling the sacks are placed on the conveyor shown in Fig. 1 running alongside of the bag-loading dock. This conveyor is a flat belt running on a bed of closely spaced ball-bearing rollers which insure a smooth-riding, flat surface for the bags to ride on. A rail has been placed along the far side of the conveyor against which the bags lean, so that they will not tip over. In this way, the bags are conveyed to the sewing machine, where they are closed; and they are then disposed of in one of two ways. First, for placing on trailers, they are deflected from the belt onto a loading table by a plow. From this loading table, they are placed on trailers as desired. Second, for box-car shipment, they discharge over the end of the bulk conveyor into a chute which conducts them to a point near the railroad shipping dock. The further disposition of these bags will be taken up under the subject of shipping.

Packing Powdered Sugar in Bulk

Reference to Fig. 2 will give the reader an outline of the conveying system used in handling powdered sugar. The bulk conveyor which receives the granulated sugar from the screen discharges into a straight

chute. Part way down this chute there is a deflector which, when in operation, delivers sugar to a branch chute. This chute delivers the sugar into a scroll or open-screw type conveyor. This latter feeds a small bucket elevator, which raises the sugar to a bin at the ceiling of the floor above. This bin in turn feeds the pulverizer mills, which discharge into a hopper, from which the powdered sugar may be loaded into barrels as desired. This hopper is also arranged to feed the automatic packing machinery, by which powdered sugar is placed in cartons.

As the demand for this particular kind of sugar in this particular package—that is, bulk barrels—is not great, there has been no necessity for installing an elaborate fixed handling system here. Instead, the empty barrels are brought to the proper position on trailers filled and then taken to the shipping or storing point on the same trailers.

Delivering Sugar to the Automatic Package Equipment

Mention has been made above of the conveyor which supplies the package department. When the granulated sugar storage bins are filled, this conveyor is fed directly from the screens—that is, if the manufacturing department is producing sugar at that time; on other occasions this conveyor may be fed by spout from the storage bins. These spouts are provided with hand-operated slide gates, and in this way can only be opened by the personal attention of the operator, so that there is little possibility of causing sugar to be fed to the conveyor when it is not desired to do so.

When sugar is fed to this conveyor directly from the screen, it is delivered from the belt conveyor under the screen to the vertical chute mentioned above. Both this vertical chute and the spouts from the bin deliver to the conveyor in the same manner. This is through an automatic loading hopper which is operated by the motion of the conveyor and which delivers to each bucket of the conveyor a certain definite amount of sugar—such an amount that the conveyor is carrying at its most efficient rate, each bucket being filled with the maximum which it will hold without any spillage.

Special Buckets Used for Sugar Handling

The conveyor used here is a pivoted bucket carrier of the type ordinarily used in power plant work for handling coal. There is one innovation here, however. The buckets are all aluminum, as is every other part of the conveyor which might come in contact with the sugar. This prevents any discoloration of the sugar by contact with iron.

The system of handling here used is shown in outline on Fig. 3. The pivoted bucket carrier may be discharged at either of two points. These discharges deliver the sugar to scroll conveyors, provided in the bottom of their casings with a series of rack-and-pinion operated gates. Under each of these scroll conveyors is a large maple-lined concrete storage bin. One of these feeds the automatic packing machinery which packs the sugar in paper cartons, while the other feeds the machinery which fills cotton bags.

Packing Sugar in Cotton Bags

There are various sizes of cotton bags such as 2 lb., 5 lb. and so on, into which sugar must be packed for the purpose of the retail trade. On the floor below the bin mentioned above, then, are located a series of bag-filling machines on which these various sizes of bags are filled. These machines are of a semi-atuomatic type. The operator takes a bag from the supply of empty bags which is placed near at hand and holds it under the filling spout of the machine. The machine automatically takes from the supply spout, through a weighing hopper, the amount of sugar desired to be placed in the bag. When the weighing hopper is filled, the supply is cut off and the contents of the weighing hopper is discharged into the bag. The operator repeats this operation, having under the filling spout an empty bag to receive each weighed discharge at the time of its occurrence.

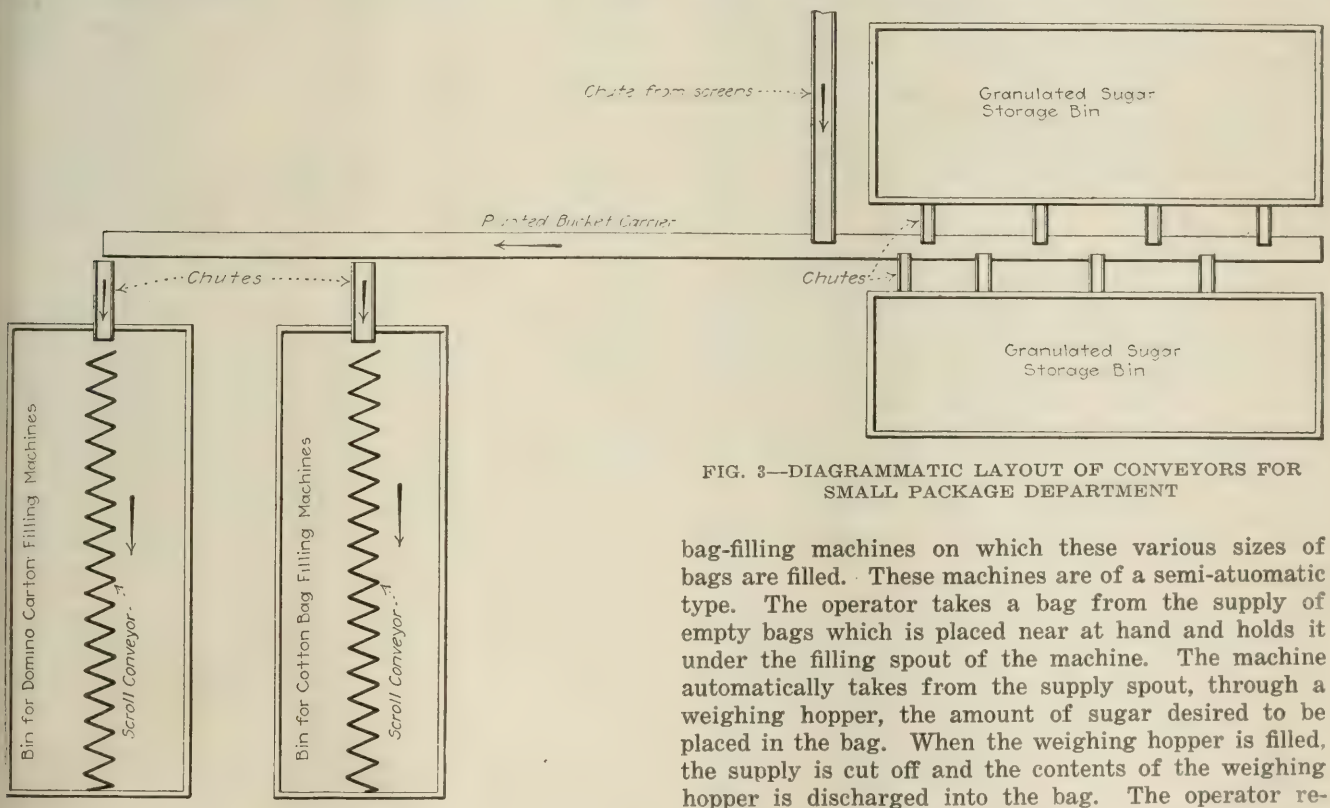

FIG. 3—DIAGRAMMATIC LAYOUT OF CONVEYORS FOR SMALL PACKAGE DEPARTMENT

The portion of the machine on which the bag rests under the filling spout is a rotating table, and after the bag is filled this carries it to a second operator. This operator is provided with a sewing machine, which is part of the filling machine, and with which the bag is closed. The rotating table then carries the finished

bag to a point where it is discharged and drops down a chute, for further disposition.

Automatic Filling of Paper Cartons

The machinery used for filling paper cartons with sugar is entirely automatic. In this machine, cartons are fed flat as shipped and the machine opens these cartons, finishes the bottom of them fast with glue and feeds them upright to the filling head. This filling head is in two parts, the cartons passing under it on a small rotary conveyor or carrousel. When the empty carton comes under the first filling spout, it is stopped by the mechanism and receives about nine-tenths of the load which it is to contain. The conveyor then carries it on under the second filling spout. The portion of the conveyor under this spout consists of an adjustable scale, which may be adjusted for various weights which the finished carton is to contain. The spout here is automatically connected with the scale and discharges a fine stream of sugar into the carton until the scale just balances, when the supply is shut off.

The carrousel then carries the filled carton beyond the spout and discharges it on to a straight conveyor which takes it through the sealing machine. In the sealing machine the top of the carton is folded down and pasted shut. An additional straight run of conveyor—flat belt type—takes the sealed carton to a packing table.

At these packing tables, operators stand who fill packing cases or large paper containers with the cartons of sugar. When these cartons are filled they are placed on a driven slatted conveyor, which conducts the cases under a nailing machine and the paper containers to a sealing department, where they are glued shut. From the nailing machine or the sealing department the filled containers are delivered to loading tables, where they may be loaded on trailers as desired. The empty containers are delivered to the packing tables by trailers also.

Packing Powdered Sugar in Cartons

The machinery used for packing powdered sugar in cartons is exactly the same as that used for packing granulated sugar in cartons except that when the carton is opened and the bottom glued shut an additional operation is introduced. This consists of forming and placing within the carton a paraffine paper lining. The general routine of handling after the cartons are filled is exactly the same as that used for cartons of granulated sugar.

Efficiency Developed in the Packing Department

The efficiency of the machinery for filling cotton bags could be determined only after a long period of observation. These machines are only semi-automatic and the rate of production from them depends entirely on the skill and willingness of the operators. The main advantage lies in the fact that they make a repetition job out of the filling—a job which may soon become automatic routine to the operator and at which high speed can easily be developed. It does not seem possible that anyone would question the increased efficiency of this filling method over a complete hand method.

The automatic equipment for filling cartons, on the other hand, presents a very definite picture of increased efficiency. The average production of these machines is twenty-eight filled cartons per minute.

The difficulties to be overcome in shipping material from this plant lie in the many points of origin of the various packages to be shipped and the fact that shipping must in no way be tied up to production, the production being free to go on without any reference to the amount of material which is shipped from the plant. For this reason all sugar shipped is placed in large sacks, in barrels or in good-sized wooden or paper containers.

This necessitates the further packing of the cotton bags in which granulated sugar is loaded. The chute which takes the cotton bags from the filling machine can deliver in two ways. One of these deliveries is made to a large sloping collecting table underneath the filling machine, and the other delivery is made to a similar collecting table a short distance away from the first one and parallel to it. At one of these collecting tables the sacks are loaded into barrels. Here the barrels are placed on shakers just as if they were to be loaded with bulk sugar and the sacks are thrown in and shaken down into a compact load. After a barrel is loaded the head is placed and the barrel is then taken to storage or shipping on a trailer.

The other collecting table is used for loading the cotton bags into burlap sacks. These sacks take 100 lb. as a complete load, and for convenience they are rested on scales during the time in which the sacks are placed in by hand. Along the side of this collecting table is a belt conveyor. This belt conveyor is exactly similar to that used at the point where bags are filled with bulk sugar and is operated in the same way, the bags being placed on it after they receive their required weight of small cotton bags and then, after passing through the sewing machine, are delivered to a table where they are loaded on trailers.

Storage With Reference to Shipment

Because of the fact that the production must go on without reference to the shipping, large storage spaces have been arranged. These storage spaces are sufficient to permit the storage of barrels, bags and containers as they are produced, until such time as they are shipped.

For this type of handling, from point of package origin to storage, and from storage to shipment, there is only one kind of conveying equipment which is thoroughly adaptable and flexible. This is the electric storage battery tractor and trailer—the system which has been adopted in this plant, and which is in general used for similar service in other industries.

As a special service for the handling of barrels the filled barrels may be delivered from the barrel-loading dock to a barrel elevator and elevated to the desired point.

This is a specially built barrel elevator which can raise and lower barrels to the various storage floors of the storage space. The trailer system is also used for barrels, however, and is used entirely for the bags and for the other containers.

In connection with the use of the trailers there have been installed large elevators of a capacity of 8 tons, with a platform about 17x17 ft. These elevators are provided with an automatic micrometer leveling device so that the operator stopping anywhere near the desired floor has to pay no further attention to his elevator, which automatically adjusts itself to the correct floor level. As the load is removed from the elevator or as the load is placed on it, this device serves to compensate for the change in loading and to keep the elevator in exact position.

The various loads are taken to the points of ship-

ment—that is the railroad car loading dock, the dock for loading trucks for local shipment, or the pier at which lighters are loaded—in every case by tractor and trailer.

The upper floors of the building, in which storage takes place, are not served generally by tractors, although this can be done if desired. The trailers are mounted on ball-bearing wheels and may be shoved easily by hand to their position on the floor or to the elevator as desired. When they are delivered by the elevator to the ground floor, they are picked up by the tractor and taken to the proper loading dock for shipment. In all cases the loading docks are as near as possible level with the carrier into which the load is to be placed, so that the trailers may be run directly into the car, lighter or truck. In this way all rehandling is eliminated and the only handling that occurs is when the container is placed on the trailer at its point of origin and when it is removed from the trailer to the proper place in the carrier in which shipment occurs.

Noteworthy Points of This Installation

The particular point worthy of note in this handling installation is the fact that it forms a unified whole. The sugar is delivered to the various packing operations, all from one central storage bin, to be carried through many diversified operations and into several forms of final shipping containers. The handling system used in connection with shipments is so arranged that all of these various containers may be handled in exactly the same way by a completely flexible system. It is readily seen that no matter how the plant may be extended the same method of packing can be duplicated, and the methods of handling to shipment would be exactly the same as at present, with the addition of possibly a few more tractors to the fleet now in use.

The large number of trailers necessitated by this system of storage and handling has been brought up many times as an objection to its use in other industries. This objection does not hold good in practice, because the use of this multiplicity of trailers absolutely eliminates any rehandling, and the non-productive labor entailed in shipping is cut to about one-third the amount which would be necessary if the usual two rehandlings were indulged in.

The writer wishes to acknowledge the courtesy of the American Sugar Refining Company in making available the date on its handling system, which solves so well a problem so often encountered.

Natural Indigo in Java

The classification of indigo in the Soerabaya market is dependent upon the percentage of indigo blue, which varies from 60 to 70 per cent. The production of indigo in Java has been rapidly declining, owing to inability to compete with synthetic indigo.

English Rail Specifications

According to a revision of the British Standard Specifications for bull head railway rails, issued in June, 1922, the chemical composition of the steel may be specified by the purchaser from the following classes (where range is not given, the figure is a maximum):

	Open-Hearth				Bessemer		
	Acid		Basic		Acid		Basic
	Ordinary	High-Carbon	Ordinary	High-Carbon	Ordinary	High-Carbon	Ordinary
C	0.45–0.55	0.50–0.60	0.45–0.60	0.55–0.65	0.40–0.50	0.45–0.55	0.40–0.50
Mn	0.90	0.80	0.90	0.80	0.70–1.00	0.90	0.70–1.00
Si	0.15	0.10–0.30	0.15	0.10–0.30	0.15	0.10–0.30	0.15
P	0.06	0.05	0.05	0.04	0.075	0.06	0.07
S	0.06	0.05	0.06	0.05	0.07	0.06	0.07

Carbon and phosphorus analyses must be made from each heat before rolling. Complete analyses must be made from every 100 tons of rails. Arsenic and copper must also be reported if desired. The rail to be analyzed is selected by the purchaser, and the drillings are taken from a ¾-in. hole driven longitudinally in the left center of the head.

One impact test (with a falling tup weighing 2,240 lb., which is described in detail) is made from every heat. A 5-ft. piece from the top rail may be selected by the purchaser, or the crop itself may be used if the maker consents. After two blows of specified height (5 to 7 ft.), the permanent set must not exceed 3.7 to 4.3 in., depending upon section and carbon content.

Furthermore, if the purchaser desires, he selects a rail from each 100 tons of material and a tensile test specimen is cut from the left center of the head. Retesting without prejudice is permitted if the fracture occurs outside the middle half of the gaged length. Tensile properties must conform to these relations:

	Ultimate Strength	Minimum Elongation in 2 In.
Ordinary carbons of any process	94 to 112,000*	15 to 12*
	112 to 119,000	10
Higher carbon open hearth	103 to 112,000	12
	112 to 123,000	10
Higher carbon bessemer	99 to 112,000	12
	112 to 119,000	10

* The minimum elongation for intermediate breaking strengths are in arithmetic proportion.

Retesting is permitted as follows: Two additional chemical tests may be made from the same heat or cast; if both pass, the entire 100 tons of rails is acceptable. If one or both fail, that individual heat is rejected, and the remainder of the lot of 100 tons treated and tested as a new lot. In this way the remainder of the lot is accepted as soon as a "cast" is found which passes the chemical test or retest. If the impact test fails, two additional tests may be made from two other rails. The heat is acceptable if both tests pass.

Retest for tensile properties follows the same procedure as retesting for chemical properties.

Ingots must be at least 200 sq.in. cross-section at the big end. They must be rolled bottom end ahead. All cold-straightening "shall be done by gradual pressure."

Storing Turpentine in Galvanized Tanks

Iron drums or tanks in which turpentine is to be shipped or stored should not be galvanized on the inside, but should be properly shellacked. This persistent white turbidity in turpentine was caused by a finely divided zinc compound held in suspension and a certain quantity of dissolved zinc. Iron oxide is also sometimes found in suspension. Shellacking instead of galvanizing will do away with this trouble.

It might be possible to ship or store freshly distilled turpentine, free from water, in iron or galvanized drums or tanks without producing this objectionable condition, but the smallest quantity of water will develop acids which partly dissolve and loosen either the iron itself or the zinc with which the iron has been galvanized. Turpentine stored over winter is practically certain to separate some water during the cold weather and any unshellacked metal surface will be attacked.

Modifications of the Sand Test For Detonators

By William M. Dehn

THE SAND TEST, as initiated by Snelling[1] and developed by Storm and Cope[2], is a rapid and practical method for measuring the explosive strengths of detonators and is based on the weights of 20- to 30-mesh standard sand crushed by their explosions. The fuse or electric detonators are imbedded in 100-gram masses of Ottawa sand contained in a suitably constructed bomb or explosion chamber of heavy steel. After the explosions, the weights of sand finer than 30 mesh are separated and weighed and the physical constants thus obtained are interpreted as the quantitative effects, or strengths, of the respective detonators.

Having had occasion recently to use the sand test and a number of questions relating to it having arisen, the writer was led to make a closer study of its operation and its principles. For example, Table I, calculated from a great volume of data of U. S. Bureau of Mines Technical Paper 125, shows remarkable regularities and raises a number of questions.

TABLE I—RESULTS OF SAND TESTS BY U. S. BUREAU OF MINES

Detonator No.	Average Weight of Charge	Percentages of Sand Retained on				Per Cent Sand Through 100-Mesh	Average Weight Sand Crushed	Sand Crushed by 0.1 g. of Charge
		40-Mesh	60-Mesh	80-Mesh	100-Mesh			
3	0.4953	14.93	18.11	10.64	6.94	49.38	22.03	4.44
4	0.6358	13.66	17.02	9.93	6.49	52.90	27.44	4.32
5	0.7220	13.11	17.06	10.10	6.61	53.12	30.90	4.27
6	0.9842	12.56	15.60	9.32	6.44	56.13	36.61	3.73
7	1.4377	11.89	15.07	9.27	6.04	57.73	47.16	3.28
8	1.8345	9.64	14.41	8.79	5.92	61.24	54.53	2.97
10	2.8691	8.12	12.69	8.64	6.16	64.39	68.74	2.40
a	*b*	*c*	*d*	*e*	*f*	*g*	*h*	*i*

Why are the strengths[3] apparently not proportional to the weights of the detonators used? Why are they apparently less and less per unit of weight, as the total weights are increased? Then, on the other hand, with increase of size of detonators, why are larger percentages[4] of sand broken up more finely? Conversely, with decrease of charge of detonators, why are relatively larger fragments[5] obtained? These and other questions were raised by earlier experiments with the sand test. Much light on these questions has resulted from an extensive study of the test, especially from use of the modified form of apparatus described herein.

Modified Testing Apparatus

The essential features of improvement in the new form of explosion chamber are shown in the figure. The metal tripod support and the heavy frame carrying the screw to hold down the cover at the point *G* are omitted. The apparatus is a transformed autoclave[6] whose interior dimensions are 4 and 9 in. The only novel feature involved is the cylindrical steel weight, 5 in. in height and nearly 4 in. in diameter; it is centrally perforated by a ¼-in. bore *DC* and weighs 6 kg. In its final and most efficient form, the lower part of the weight was bored out hemispherically as indicated by the line *C*. Earlier forms, such as the flat-bottom form *A* and the partly cupped form *B* are indicated in the figure. The detachable hook is used to lower and to raise the weight.

Methods of Using Detonation Bomb

A 500-gram charge of Ottawa sand, freshly standardized to the 20-mesh and 30-mesh sieves to be used, is placed in the detonation bomb. The fuse or the wires of the attached detonator are passed through the hole of the weight at the cup end and the detonator is adjusted so as to touch the weight and maintain a vertical position. The weight with attached detonator, is then lowered by means of the hook *E*. After detaching the hook the weight is pressed down by hand so that the sand fills the cupped bottom; then the detonator is adjusted in the sand to a height estimated to be centrally and symmetrically located. By means of a gas pipe the weight is tamped down until the character of the sound of the blows indicates that the sand under the weight is uniformly and completely packed. This tamping should begin with moderate force and should not disturb the upright position of the weight. Finally, stronger blows of the pipe will give the desired compactness. The fuse or the wires are next run through the tube *F* of the cover, the latter is screwed down tightly and the charge is fired, preferably with the apparatus resting on a concrete floor. The explosions usually impart "kick" to the apparatus, but no sand is ejected therefrom. The cover of the bomb is taken off and the steel weight is elevated by the hook. The sand is then poured and brushed onto a stout piece of paper. No special precautions need be taken to collect the dust finer than 100 mesh.

Since only sand larger than 30 mesh and 100 mesh

respectively are weighed—the sand finer than 100 mesh being calculated by difference—no attention needs to be given to the dust inevitably lost to the air during the explosion or while transferring and sifting. The sand is first run through a 20-mesh sieve for the purpose of removing some of the pure white, extremely fine sand found to be in a packed condition, also to remove fragments of the fuse and detonator cap. All of this material is thrown away. Next the sand is poured onto a 30-mesh sieve. Since many masses of white crushed and packed sand are found, they are powdered on the sieve by means of a cork attached to a stick, using it as a flat-bottom pestle. These compact masses of powdered sand give trouble during the stages of sifting, but their removal is necessary to secure accurate and concordant data. After all of the 30- to 100-mesh sand has been collected, it is again run through the 30-mesh sieve by shaking but not by using the cork pestle. In this manner a quantity of 20- to 30-mesh sand will be recovered and this must be returned to the main bulk of 20- to 30-mesh sand, because the cork will always force through the sieve some sand which will not pass through by ordinary shaking.

In this connection it is of interest to note that under the microscope Ottawa sand is observed to be spherical or spheroidal in form, with no flat or conchoidal surfaces; but after explosions, unchanged sand, sand with one flat or conchoidal surface, and sand with two or more such surfaces are observed. The original round sand is extremely resistant to comminution by friction with the cork pestle; the sharp edges of the broken fragments are quite easily broken off. Hence the total sand crushed is subject to little effect by the pestle, but the percentage of the sand finer than 100 mesh may be varied through long-continued rubbing with the pestle. A blank run to determine the sand crushed by tamping in the bomb and by the rubbing with the cork under the above conditions gave less than 0.5 gram of sand from the 500 grams used.

Features of Improved Apparatus

The essential improvements of the detonation apparatus over that of Storm and Cope are as follows:

1. A heavy weight is superimposed on the charge of sand so as to subject the latter to more of the explosive strength of the detonator.
2. The weight is cupped at its bottom so that the detonator explodes in the center of a ball of sand, thus giving a more symmetrical distribution of the explosive effect of the detonator.
3. The charge of sand is 1 lb., or preferably 500 grams, instead of 100 grams, so as to supply a sufficient excess of material upon which the detonator can exert its power.
4. Only two fractions of sand finer than 30 mesh are determined; hence the practical application of the sand test is greatly simplified.

Other incidental details of improvement of this test are obvious or will be indicated.

Function of Weight of Bomb

In connection with the use of the weight over the sand subjected to the force of detonating charges, it may be observed here that 100 to 200 per cent more crushed sand can be obtained by this means than Storm and Cope obtained in their experiments. For example, their average for a No. 6 cap was 36.61 grams of sand, while the improved apparatus gives a value for the same cap of 85 grams. From these data and others given in the accompanying tables, it is evident that the greater confinement of the sand under a weight permits of utilization of more of the power of the detonator than could be secured in the Storm and Cope bomb with only 100 grams of unconfined sand. In their experiments most of the power of the detonators was dissipated in a sand bombardment of the walls of the bomb without subjecting all of the grains to the critical intensity force necessary to shatter.

Whereas, on the one hand, it is admitted that no known test for the strengths of detonators can measure all of the energy liberated, yet, on the other hand, any modification of a test like the sand test which gives a closer approximation to the total and true value is likely to be the more accurate and useful.

The mass of metal superimposed on the sand—namely, 6 kg.—in the apparatus described can be increased with accompanying increase of sand crushed. The total mass of metal thus used must be limited by estimates of the strength of the detonation bomb and of economy of the standard sand to be used, with incidental attention given to the control of gases developed so as to avoid blow-out of sand.

It was found that the cupped-out bottom gave substantially 25 per cent more crushed sand than the heavier but flat-bottomed weight. The effects of this form, therefore, is not only to lessen the ballistic effect on the weight but also to supply a symmetrical distribution of force lines of the explosive.

Details Regarding Sand Used

The quantity of sand to be used in the detonation bomb may be varied, but it has been found that 500 grams gives the desirable ball-like form in the bomb and for purposes of economy of sand and of reduction of labor in sifting this mass may be considered a good practical limit. The writer believes Storm and Cope used far too little sand in their experiment, since a No. 7 cap can break up more than the total sand used by them.

Tamping of the sand under the weight was found to be necessary to give concordant and maximum effects of detonation. Such tamping not only assures elimination of relatively large air spaces under the weight but also gives a packed condition of the sand amounting to about 5 per cent. Increase of compactness was obtained by mixing with small percentages of water. The incompressibility and capillarity of the water, as well as its displacement of air, increase the "hammer and anvil effect." Too much water, however, causes a decrease of demolition owing to diversion of explosive energy to heat of vaporization.

The convenience of measuring only two fractions of broken sand is obvious not only in lessening the labor of analysis, but the two fractions empirically chosen have been found to serve a definite and useful purpose. For example, it will be observed that the percentages of sand finer than 100 mesh as determined by Storm and Cope varied for the respective detonators from 49 to 65. The percentages of sand finer than 100 mesh as determined in accordance with the method of this paper have fallen usually between 40 and 55.

Why are there such wide differences, especially in the case of the large detonators as used by Storm and Cope? The answer is obvious—namely, incomplete detonation effect on the sand is indicated by a high percentage of sand smaller than 100 mesh. Evidently the

sand next to the detonator will be broken most finely, hence limited and incomplete effects will be indicated by higher percentages of the finer sand. Conditions that will produce this effect are: too little sand; too big a detonation charge; faulty confinement in the detonator capsules; imperfect exterior compression resulting in local blow-out; asymmetric installation of the detonator in the mass of sand, resulting in irregular distribution of the force lines of the explosive; variations in the shape and size of the detonators used; variations in the size and shape of the sand used.

The first of these two conditions are illustrated by the data of Storm and Cope; the effects of most of the other conditions are obvious; the effects of variations of the size and shapes of the detonators and of the sand used introduce a number of interesting questions.

Demolition Values Depend on Surface as Well as Weight

Since masses vary as the cubes and surfaces as the squares, it is possible that different weights of the same explosive cannot reveal by the sand test, or indeed by any test, strengths directly proportional to such weights. For example, assume that the explosive spherically occupies 1 c.c. and 2 c.c. respectively. Then the surfaces exposed will be in the ratio of 1 : 1.59 instead of 1 : 2, and the explosive power cannot be exerted under identical conditions of space distribution. Now, because the gas generated by an explosive, especially of the detonating type, exerts its power most intensely at the surfaces confining the explosive, while ballistic pressure effects are conducted to varying distances in advance of the expanding sphere of gases, it is evident that the total area of such surfaces initially exposed is a very important factor as influencing the final total effect. This is especially true when small weights are involved or when the explosives are highly brisant. Under these conditions, as the spheres of gases expand, the intensity factor falls off rapidly for a number of reasons, chief of which are the cube-square relation and the cooling by adjacent materials. Since a critical intensity factor is necessary to crush sand and other materials, it is evident that under adverse conditions of space distribution much of the energy of detonating explosives may be dissipated as heat or by transformation to ballistic effects. For example, in Table II it

TABLE II—RELATION OF DEMOLITION TO SURFACE AND WEIGHT

Det. No.	Ratios of Surfaces	Ratios of Weights	Sand Crushed Surfaces	Sand Crushed Weights	S. and C.	Dehn	Relative Strengths S. and C.	Relative Strengths Dehn
6	4.50	0.9842	1.00	1.00	36.61	85	1.00	1.00
7	5.77	1.4377	1.28	1.46	47.16	111	1.29	1.30
8	5.95	1.8345	1.32	1.86	54.53	135	1.49	1.59

is obvious that the sand test does not give values for demolition strictly proportional to the weights used, but values intermediate to the ratios of surfaces and the ratios of weights. It is further obvious that that test best measures the strength of an explosive which gives values most nearly proportional to the weights used. The cube-surface relation of explosives will be investigated further.

Study of Optimum Size of Sand

Investigation of the size of the sand used in this test brought out some very interesting observations which are shown in Table III. In study *A*, rounded Ottawa sand differing slightly in diameter gave more demolition with smaller grains—that is, with sand pos-

sessing the greater surface exposed to the power of the explosive. This study emphasizes the necessity of using sand of narrow mesh variation; certainly if 20- to 30-mesh sand is used, it should be thoroughly mixed after running through the sieves.

From study *A* it may be concluded that sand finer than 20- to 30-mesh can be advantageously used for the sand test. This is neither proved nor disproved by study *B*, since only sand previously crushed by detonators was used therein. However, study *B* does prove that a limit to such fineness of sand is reached for maximum crushing effect and that this maximum probably lies between 30- and 120-mesh. It must be remembered that the crushed sand possesses flat conchoidal surfaces and partly cracked texture; hence the optimum fineness cannot be estimated accurately from the data given.

Since the total surface of a given mass of sand can be increased thousands of times through comminution, while the explosive intensity factor remains a constant, it is easy to understand that too fine a division of the sand will result in the following: Dissipation of energy over too large a surface, a lowering of the critical intensity factor below the value necessary for crushing, and in a conversion of such crushing force to heat and ballistic effects. Furthermore it may be assumed that the

optimum sand size will differ for different explosives, since the explosives themselves possess different intensity factors for crushing.

If this prove true, then the strengths of detonators of different compositions cannot be compared accurately on the basis of the values obtained with the same quality of sand. This and other related questions will be investigated. Miscellaneous data, illustrating the foregoing discussions and conclusions are given in Tables IV and V.

Summary

Sufficient sand should be used to yield a practical maximum of crushing. It should be rounded and of a diameter practically uniform and sufficiently small to approximate the optimum fineness for the detonator used. Sand recovered from one test should not be used for a second test.

Confinement of the sand should be effected by a heavy weight of special design and the whole should be tamped down to a maximum compression.

The detonator should be inserted symmetrically in the ball-like mass of sand.

Different weights of the same detonator, or indeed equal volumes of the same differing in density, cannot exert crushing effects on sand directly proportional to the weights used.

Comparisons of the strengths of different detonators, as determined by the sand test, are only approximate.

Rule of Implied Warranties in Sales Enlarged by Uniform Sales Act

In the case of H. Klaff & Co. versus Luria Bros. & Co., Inc., Klaff brought suit to recover a balance alleged to be due for several carloads of metal sold and shipped between March 15 and June 5, 1920. The amount of this balance was admitted, the dispute being only as to the validity and amount of Luria Bros.' claim of set-off arising out of a previous sale of five carloads of steel shells by Klaff to Luria Bros., shipped from the Naval Proving Ground at Aberdeen, Md., to Luria Bros. at its yard in Reading, Pa., and reconsigned by them to the Carpenter Steel Co., also at Reading. The Carpenter company rejected three of the five cars and Luria Bros. tendered a return of same to Klaff, who refused to receive them. The claim of set-off was for the purchase price paid by Luria Bros. for the rejected cars, together with demurrage charges.

In this case the seller of the steel shells was a broker or dealer and not the manufacturer. Defendants defended on the ground that they were purchased as scrap steel for remelting and were unfit for that purpose. They further contended that the seller knew the purpose for which they were purchased, and therefore there was an implied warranty that such material was reasonably fit for that purpose.

Former Law of Implied Warranties

Much confusion arose over a rule of law established in most of the states prior to the uniform sales act and now modified by this act. In a suit of the Queen City Glass Co. against the Clay Pot Co. (97 Md., 429), the law of implied warranties was laid down. This was cited in a subsequent case (114 Md., 172) as follows:

"Where a manufacturer contracts to supply an article which he manufactures to be applied to a particular purpose so that the buyer necessarily trusts to the judgment or skill of the manufacturer, there is in that case an implied term of warranty that it shall be reasonably fit for the purpose to which it is to be applied. In such a case the buyer trusts to the manufacturer or dealer and relies upon his judgment and not upon his own."

Seller Included Under Uniform Sales Act

Now the uniform sales act puts the seller, who is not the grower or manufacturer of the thing sold, in the position which was formerly held by the manufacturer or grower only, in reference to the implied warranty of the goods sold.

Section 36 provides: "Where the buyer, expressly or by implication, makes known to the seller the particular purpose for which the goods are required, and it appears that the buyer relies on the seller's skill and judgment (whether he be the grower or manufacturer or not) there is an implied warranty that the goods shall be reasonably fit for such purpose."

In a former case it was held that "when the seller is not the manufacturer of the article sold and the buyer has an opportunity of examining it there is no implied warranty, in the absence of fraud, that it shall be fit for the purpose for which it was bought. In such cases, if there be no express warranty, the doctrine of *caveat emptor* applies, and the buyer not having seen fit to exact a warranty, takes upon himself the risk as to quality."

Distinction Between Dealer and Manufacturer Eliminated

The sales act in effect qualifies this doctrine of *caveat emptor*. Goods thus sold may be found to be merchantable and yet not reasonably fit for the purpose for which they were required and if the buyer relies on the seller's skill and judgment in selecting the goods the doctrine does not apply. The important distinction between the dealer's and manufacturer's implied warranties as to the quality of their goods was apparently wiped out and they now stand on common ground.

In Pennsylvania the question arose in the case of Griffin vs. Metal Products Co. and the Supreme Court of that state declared the law there to be settled. It construed a contract for the sale of high-speed steel; and the question whether there was an implied warranty that the steel should be reasonably fit for the purpose for which the seller knew it was to be used was decided in these words:

"Before the passage of the act [the uniform sales act] it had been repeatedly so held, so far as relates to the grower or manufacturer of the goods sold, and the only change made thereby was to extend the rule to every seller 'whether he be the grower or manufacturer or not.'"

The contrast is well set forth in Benjamin on Sales (6th English Edition), page 716: "The distinction taken at common law between cases where the buyer had an opportunity of examining the goods and those in which he had none . . . has been abrogated by the code [referring to the uniform sales act]. Instead of a presumption that a buyer, who might have in-

spected the goods, bought on his own judgment, in future whether he so bought or not will be a question of fact, and an opportunity of examination and even an actual examination will be immaterial. And no distinction is drawn by the code between contracts of sale of specific as distinguished from those of unascertained goods. At common law the buyer of a specific thing for a particular purpose took the risk of the fitness of the thing bought."

Further, it was contended by the seller that since the buyer had used two carloads of the steel shells it could not then rescind the contract and return the part unused, since it was admitted that there was no difference between the material in the cars used and that unused. But the court points out that the price of the goods was not a lump sum for the five carloads, but $25 per ton; and there was no evidence to show that the price per ton depended upon the quantity ordered, or that the seller was in any way injured by the failure of the buyer to return all the cars. The court says under these circumstances the failure to return all the shells would only bear on the buyer's good faith.

Rights of an Owner of a Trade Secret

Some of the rights of an owner of a trade secret are set forth in the recent case of the Cameron Machine Co. against the Samuel M. Langston Co. and others (115 Atlantic, 212). Here the complainant sought an injunction to restrain the defendant Sieg from divulging secret features of certain machines manufactured by it, and to restrain the defendant company and Samuel M. Langston from using any information respecting such secret features which they, or either of them, obtained from Sieg.

The two companies were competitors. From time to time each company placed upon the market new and improved types of their own special make machines. From 1915 to 1919 complainant had in its employ an erector named Schatten; and about October, 1919, Schatten entered the employ of the Langston company. The defendant Sieg was employed by complainant from March, 1917, to May, 1920, when he also entered the employ of the Langston company.

Claims Secret Features Were Disclosed to Competitor

The bill charged that the Langston company induced Sieg to leave the services of complainant for its own employ for the purpose of obtaining from him knowledge of the secret features which complainant had embodied in the design for two certain improved machines which Sieg had designed for it. It further charged that Sieg, in violation of his duty to complainant, disclosed to the defendant company the secret features of its own machines, which he had designed for it, and that the defendants thereupon designed and manufactured a similar machine, copying and making use of all the secret features of complainant's machines.

Defendants denied the charges against them and asserted that there were no secret features in complainant's machines; that most if not all of the so-called secrets were old in the art; that such had been used in their own machines years before the new types of complainant's machines. And they further asserted that the complete designs for complainant's new machine were not in existence at the time Sieg left its employ; and that the exhibits used to establish such similarity are fictitious designs made solely for the purpose of the case, and after it had become possessed of a completed design for defendant's machine.

From the evidence the court could not say with certainty that there were any secret features or elements of complainant's designs which Sieg appropriated and divulged to the defendant company and which are used or embodied in its new machine. Neither was there satisfactory proof that any such secret features existed. On these facts the Chancellor dismissed complainant's bill of charges.

Otherwise the case brought out an interesting proposition. A "trade secret" was defined to be "a plan, or process, tool, mechanism or compound, known only to its owner and those of his employees to whom it is necessary to confide it."

Injunction Will Lie Against Employee Divulging Trade Secrets

Now, if the employee comes into possession of such trade secrets through a confidential relation with his employer, the law will raise an implied contract to prevent him from divulging any information he may have obtained as to the trade secret.

In Stone versus Graselli Chemical Co. (55 Atlantic, 736), the court held that a manufacturer whose goods are made under an unpatented secret process is entitled to protection by injunction against the divulging of his secret in any proper case.

This case, as well as others, also adopts the principle that employees of one having a trade secret, who are under an express contract, or a contract implied from their confidential relationship to their employer, not to disclose that secret, will be enjoined from divulging the same to the injury of their employer, whether before or after they have left his employ, and that other persons who induce the employee to disclose the secrt, knowing of his express or implied contract not to disclose the same, will be enjoined from making any use of the information so obtained.

Secrecy in Industry Fools Only the Secretive, Says Geological Survey Head

"Experience in dealing with producers of different commodities has shown that secrecy is largely a method by which producers have been fooling themselves," says George Otis Smith, the director of the U. S. Geological Survey, who has had long contact with production statistics. "Those who really wish to know the scope of competitors' activities have plenty of ways to find out. Secretive operators, who eventually decided to change their methods, have been surprised very much on disclosing their secrets to find that these secrets already were well known to their competitors."

This comment was occasioned by correspondence with S. K. Colby, the president of the American Magnesium Corporation. There was some hesitancy as to whether the Survey's annual chapter on magnesium should be written, as there is only one company active in its production. Presumably the company is entitled to keep its results to itself. An effort was made, however, to get permission to use these figures so that the Survey's records would be continuous. In his reply furnishing the figures, Mr. Colby expressed his hope that the chapter would be printed, so as to record the progress in the industry. He stated that his company had nothing to lose by having the quantity of metal produced by it made public.

Mechanical Properties As Affected by Grain Size

Grain Boundaries Add a Certain Stiffness to the Metallic Aggregate — Fine Grain Therefore Generally Involves Higher Tensile Strength and Hardness, and Greater Reduction of Area — Maximum Elongation Requires Medium Grain Size

By Zay Jeffries and R. S. Archer

TWO recent contributions[1] have defined, in a general way, the mechanical properties of pure metals. It was also remarked that the structure of the metal had a very profound effect on the results to be had from various physical tests. The simplest type of structure, of course, is that where the entire sample consists of one huge crystal, consequently the properties of the individual crystalline grain were given.

We now purpose to discuss how variation in the average size of the crystalline grains comprising the metal may be expected to influence the mechanical properties of the aggregate.

Support at Grain Boundaries

The continuity of the planes of easy slip is broken at grain boundaries. Any movement of blocks or fragments of one grain is opposed by adjacent grains which because of their different orientations cannot yield easily in the same direction. Disorganized or amorphous metal which is probably present at the grain boundaries acts as an additional source of rigidity (at low temperatures). Above the recrystallization temperature flow takes place at the grain boundaries, so that they are sources of weakness rather than of strength.

The mutual supporting action of adjacent grains is shown clearly in Sykes' molybdenum wires, Fig. 1, where the grain boundaries stand out like joints in a piece of bamboo. It is evident that the supporting action is effective to a considerable distance within the grains. We should therefore expect a shortening of such grains to result in an increase in strength, even though they still extended across the entire section of the wire. When the number of grains on the cross-section is also increased, the supporting action becomes still greater. Thus at 300 deg. C. Sykes obtained the following values for tensile strength vs. grain size:

Average Grain Diameter	Tensile Strength Lb. Per Sq.In.
Single grain	32,000
0.0011 in.	51,000
0.0002 in.	96,000

This increase in strength (and hardness) with decrease in grain size is characteristic of metals below their recrystallization temperatures. The quantitative relation of strength to grain size varies with the metal involved, the temperature of test, the rate of loading and the size of the piece, since it is not only a question of absolute grain size but also of the number of grains on the cross-section. When the number of grains on the cross-section is fairly large, however (say 1,000 or more), the absolute grain size is the important thing.

In the tests reported by Carpenter and Elam,[2] which were carried out at room temperature, the tensile strength of single crystals of aluminum of 99.6 per cent purity was found to vary from 6,270 to 9,180 lb. per sq.in. The same material treated to produce an average grain diameter of 0.0667 in. had a tensile strength of 10,440 lb. per sq.in., an increase of 66.5 per cent over the lowest and 13.7 per cent over the highest value for the single grains.

A most thorough correlation of grain size and Brinell hardness, measured at room temperature, has been worked out for alpha brass (68:32) by Bassett and Davis.[3] This alloy consists structurally of a single homogeneous solid solution, and is quite comparable to a pure metal. Some typical values obtained in one series were:

Average Grain Diameter	Brinell Hardness
0.014 in.	41.7
0.0046 in.	49.2
0.0030 in.	52.4
0.0014 in.	62.4
0.00093 in.	77.4

Observers are sometimes surprised to find that a very apparent difference in the grain size of two specimens is not accompanied by any marked difference in hardness. Referring to the second and third specimens in the table above, it will be seen that an increase in grain diameter of over 50 per cent has decreased the hardness only about 6 per cent. The difference in grain size would be quite apparent under the microscope, while the difference in hardness would be noticed only by measurements made with rather more than ordinary care. On the other hand, a similar increase in grain size between the last two specimens is accompanied by a marked difference in hardness. The effect of a given percentage difference in grain size is greater the smaller the grains.

Grain Size vs. Hardness at Higher Temperatures

When ductile metals are broken "cold"—that is, below their recrystallization temperature—fracture normally takes place through the grains and avoids the grain boundaries. At temperatures just under the melting point, metals are quite weak and fracture is intergranular. There is a range of temperature above that of recrystallization in which either transcrystalline or intergranular fracture may be produced at will by varying the rate of loading and duration of load. Slow loading and prolonged application of load favor intergranular fracture at low unit stress.

[2] "The Production of Single Crystals of Aluminum and Their Tensile Properties," *Proc. of Royal Society*, A, vol. 100, 1921; abstracted in *Chem. & Met. Eng.*, vol. 26, p. 514, March 15, 1922.

[3] "A Comparison of Grain Size Measurements and Brinell Hardness of Cartridge Brass," W. H. Bassett and C. H. Davis, *Trans.*, A.I.M.E., vol. 60, p. 428.

Under these conditions the grain boundaries are sources of weakness rather than of strength. Accordingly at high temperatures the relation between strength and grain size is reversed, and the large-grained specimens are the harder. There must then be an intermediate temperature at which strength and hardness are little affected by grain size. This is the "equicohesive temperature." The following account of some experiments is taken from a paper by one of the authors:[4]

"Tests have been made on iron, tungsten, platinum, gold and silver. Small wires of these metals were drawn to a diameter of 7 to 8 mils in such a manner that the structures were fibrous—that is to say, a considerable amount of working on these metals was performed at temperatures below their annealing temperatures. Some pieces of each of the wires were heated by the passage of electric current, the temperature and time conditions being maintained in such a manner as to cause recrystallization and to produce one set of each of the metals composed of small equi-axed grains and another set composed of large equi-axed grains. The fine-grained and coarse-grained samples of the same material were compared with respect to the resistance to bending at various temperatures. Small hairpins were formed from each of the wires. Let us take the pair of silver wires as an example. The arms of each hairpin were 2 in. long and the distance between the two ends was $\frac{3}{4}$ in. A clamp consisting of two steel bars was used to hold the hairpins. Two hairpins, one of fine-grained and the other of coarse-grained silver wire, were put in the clamp a short distance apart. It was found that a rider weighing 0.2 gram suspended on the ends of the hairpins would not cause a permanent deformation in either the fine-grained or coarse-grained samples at room temperature, but would cause permanent deformation of the wires at slightly higher temperatures. The steel clamp holding the two silver hairpins in a horizontal position was inserted in a muffle furnace and the temperature was gradually raised. At temperatures lower than 250 to 275 deg. C. the fine-grained silver wire was the stronger—that is, it would hold the given weight with less deformation or bending than would the coarse-grained silver wire. Above 275 deg., however, the fine-grained silver wire had been deformed or bent to a greater extent than the coarse-grained one. The conclusion is that the fine-grained and coarse-grained silver had the same resistance to deformation at 250 to 275 deg. C.; that at temperatures less than this the fine-grained silver has the greater resistance to deformation, while at higher temperatures the coarse-grained silver has the greater resistance to deformation. These tests were performed with the other metals named and the results are given in Table I. The iron and tungsten wires were heated with electric current in an atmosphere of hydrogen in order to prevent oxidation. The temperatures were measured with an optical pyrometer. The gold and platinum wires were heated in a muffle, the same as the silver, and the temperatures were measured with a thermocouple.

TABLE I

Kind of Wire	Diameter, In.	Equicohesive Temp., Deg. C.
Iron	0.007	550 to 600
Tungsten	0.007	1350
Silver	0.0075	250 to 275
Gold	0.0085	275 to 300
Platinum	0.0075	525 to 550

"The wires used for the hairpin tests were examined microscopically to make certain that the heat-treatment had produced the desired grain size. The fine-grained wires were made by heating the cold-worked wires quickly to a temperature considerably above that of recrystallization and the coarse-grained samples were produced by heating slowly through the recrystallization range followed by heating to a temperature near the melting point. The heating was done by passing electric current through the wires."

It will be noted that the equicohesive temperatures found for these metals correspond closely with their respective temperatures of recrystallization. This relation is a general one, having been found to hold for all metals investigated. Some experiments on zinc, lead and tin, which recrystallize at or below room temperature, are interesting. Quoting again from the paper mentioned above:

"Some pure zinc, lead, tin and aluminum were cast in such a manner as to produce coarse-grained structures. One piece of each of the castings was tested for Brinell hardness as cast and one piece of each was cold-hammered, after which the Brinell hardness was determined. The cold-hammering of the zinc was continued until cracks began to form at the edges of the piece. In testing for hardness, 500 kg. pressure was used with the zinc and aluminum, 200 kg. with the tin, and 100 kg. with the lead.

"It was noticed with all of the samples with the exception of the aluminum, that when the load was brought up to the required amount the beam of the balancing mechanism of the Brinell machine would very quickly fall. When the pressure was again brought up to that required, say for the zinc 500 kg., the beam would again drop. This means that the pieces of lead, zinc and tin were gradually deforming under constant load. The pressure was maintained at the required amount until the beam at a constant position of the specimen table would remain in a substantially constant position.

"With both cast and cold-hammered aluminum, the beam remained in a substantially constant position after the load was first brought to the required amount. A very slight lowering was noticed, but the effect of increasing the time of exposure of a given load was practically nil on the resulting hardness.

"This slow deformation was the most marked in the tin. It was more pronounced in the cold-hammered samples than in the cast samples and the maximum effect was found in the cold-hammered tin. When the hardness tests were carried on in such a manner that there was substantially no further deformation in the pieces of metal with constant load, it was found that the cold-hammered aluminum was harder than the cast aluminum, whereas the cold-hammered lead, tin and zinc were all softer than the same metals in the cast state.

"To obtain an idea of the rate of deformation of the pieces of lead, tin and zinc, the diameter of the impression of the ball of the Brinell hardness machine was measured on each of the samples after the load had first registered the required amount. For example, the tests on zinc were made as follows:

"The piece of cast zinc was put in the Brinell machine and the pressure raised quickly to 500 kg. Then the piece of cold-hammered zinc was inserted in the machine and the pressure raised to 500 kg., the rate of application of the load being the same in both cases. The hardness numbers were then calculated. It was found that the hardness of the cold-hammered pieces of aluminum, zinc, lead and tin was greater when determined in the above manner than that of the same metals in the cast state. The results of the hardness tests are given in Table II.

TABLE II—HARDNESS OF WHITE METALS, CAST AND HAMMERED

		Load Sustained		Quick Release of Load	
Material	Pressure in Kg.	Diam. of Impression in Mm.	Hardness	Diam. of Impression in Mm.	Hardness
Cast aluminum	500	4.75	26.5	4.75	26.5
Cold-hammered aluminum	500	3.70	44.8	3.70	44.8
Cast zinc	500	4.15	35.3	3.65	46.2
Cold-hammered zinc	500	4.20	34.5	2.90	74.0
Cast lead	100	4.85	5.10	4.70	5.44
Cold-hammered lead	100	5.05	4.66	4.30	6.54
Cast tin	200	5.65	7.30	5.10	9.12
Cold-hammered tin	200	6.8	4.72	4.6	11.32

"It is known that the equi-axing temperature of zinc after severe cold-work is not far below room temperature, and the hardness results would indicate that the equicohesive temperature of zinc would be only slightly below room temperature. The equi-axing temperatures of severely cold-worked lead and tin are considerably below room temperature, and the hardness results given in Table II would indicate that their equicohesive temperatures would also be considerably below room temperature. The equi-axing temperature of severely cold-worked aluminum is about 200 deg. C. with 1 hour's exposure at that temperature. The hardness results in Table II show that the equicohesive temperature of aluminum must be considerably above room temperature."

The lead and tin referred to as "cold-hammered"

[4] "The Amorphous Metal Hypothesis and Equicohesive Temperatures," Zay Jeffries, *J. Am. Inst. Metals*, vol. 11, p. 300.

were found by microscopic examination to be fully recrystallized, and therefore representative of normal fine-grained metal as distinguished from the coarse-grained cast specimens. It may be added that the duration of "sustained" load in the tests reported in Table II was about 15 minutes for the aluminum and about 1 hour for each of the other metals, while "quick release" was in each case after approximately 10 seconds.

These results bring out in a striking way the fact that the equicohesive temperature, as well as the recrystallization temperature, is dependent on the time factor. The temperatures at which the Brinell hardness is independent of the grain size are, for lead and tin, above room temperature for rapid loading but below room temperature for slow or prolonged loading. The equicohesive temperature of copper has been found to lie above 950 deg. C. for rates of loading producing rupture in about 3 seconds, whereas for very slow loading it is in the neighborhood of 300 deg. C. In general the equicohesive temperature is higher the more rapid the application and the shorter the duration of load.

Grain Size vs. Elongation

The elongation found on single-crystal test-bars of aluminum by Carpenter and Elam ran up to 87 per cent, as compared with about 37 per cent on bars with an average grain diameter of 0.0067 in. When there were two or three crystals on the cross-section, the elongation was less than 87 per cent, but greater than the elongation on the fine-grained bars. In Sykes' tests on molybdenum wires[5], on the other hand, the elongation was less on the wires composed largely of single crystals than on other wires of smaller grain size. These results are not contradictory, as the conditions of test were different. The gage length of the molybdenum wires was eighty times the diameter, and the elongation measured was the general elongation. Furthermore, the gage length included several grain boundaries, at which, as we have seen in Fig. 1, the deformation was relatively slight. Carpenter and Elam used test-bars in which the ratio of gage length to cross-section was relatively small, so the measured elongation was greatly increased by the high reduction of area, and the gage length consisted entirely of a single crystal. If the elongation on the molybdenum wires had been measured over the single crystal in which the break occurred, the per cent elongation would have been much higher. Unfortunately no tests have been made on single crystals having a sufficiently great ratio of gage length to diameter so that the general elongation could be measured, unaffected by the local stretch.

FIG. 1—SINGLE GRAIN MOLYBDENUM WIRE BROKEN IN TENSION (SYKES)

In general the grain size conducive to maximum elongation is neither extremely fine nor extremely coarse. The actual grain size which will give the highest elongation for any particular metal depends on the size and shape of test-piece, the temperature of test, and rate of loading. Curves given in Fig. 2 show how the relation between grain size and elongation in molybdenum depends on the temperature. The fine-grained wire, which had the greatest elongation at temperatures below 200 deg. C., had the least elongation at 900 deg. C.

The effect of grain size and diameter of test specimen on the elongation and reduction of area of Armco iron is shown in Table III.

TABLE III—EFFECT OF DIAMETER AND GRAIN SIZE ON TENSILE PROPERTIES OF ANNEALED ARMCO IRON

Diameter, In.	Grains Per Sq.In.	Tensile Strength, Lb. Per Sq.In.	Elongation, Per Cent in 2 In.	Reduction of Area, Per Cent	Number of Grains Across Diameter of Wire
0.204	400	41,000	30.0	76.0	100
0.025	810	48,550	12.5	76.0	18
0.023	2680	48,200	23.7	78.0	30

Table IV shows the required tensile strength and elongation of annealed copper wires of various diameters as specified by the American Society for Testing Materials.

TABLE IV—TENSILE STRENGTH AND ELONGATION REQUIRED IN SOFT ANNEALED COPPER WIRE

Diameter, In.	Tensile Strength, Lb. Per Sq.In.	Elongation, Per Cent in 10 In.
0.460 to 0.290	36,000	35
0.289 to 0.103	37,000	30
0.102 to 0.021	38,500	25
0.020 to 0.003	40,000	20

Lower elongation in small wire and thin sheet or strip is a general observation in metals. But as shown in Table III, a small grain size seems conducive to high elongation in small wire or thin strip.

Brittleness

Brittleness in metals may be due either to brittleness of the grain boundaries or to lack of plasticity in the crystals themselves. Equi-axed tungsten breaks in a brittle manner at temperatures below 200 deg. C., the

[5] "Effect of Temperature, Deformation, Grain Size and Rate of Loading on the Mechanical Properties of Metals," W. P. Sykes, *Trans.*, A.I.M.E., vol. 60, p. 780.

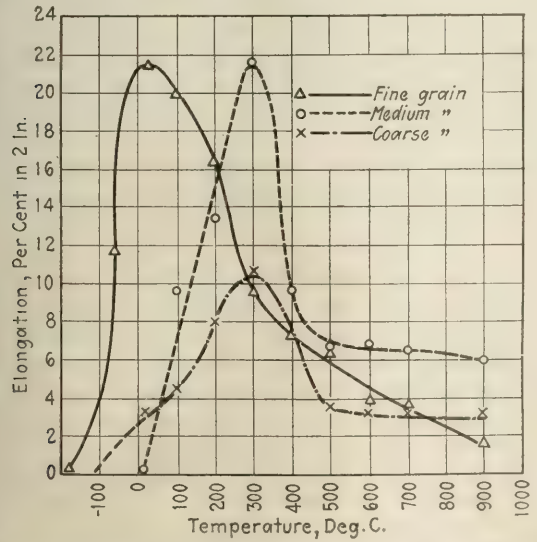

FIG. 2—EFFECT OF TEMPERATURE AND ELONGATION OF ANNEALED MOLYBDENUM WIRE. (SYKES)

fracture taking place almost entirely at the grain boundaries. Individual crystals of tungsten appear to be somewhat plastic. The low-temperature brittleness is therefore due to brittleness at the grain boundaries, a condition which is consistent with the view that the grain boundary metal is amorphous and that the amorphous metal increases in hardness and brittleness, as the temperature is lowered, more rapidly than does the crystalline. Coarse-grained zinc is but slightly ductile at room temperature, whereas fine-grained zinc may have an elongation as high as 90 per cent. In the coarse-grained zinc, the fracture takes place largely through the grains. Both fine-grained and coarse-grained zinc are brittle in liquid air, the fracture again taking place chiefly through the grains. Brittleness in this case is therefore due to lack of plasticity in the crystalline grains themselves. In either case small grain size favors the retention of ductility at low temperatures.

Reduction of Area

The first yielding of a tensile test-bar of a ductile metal involves a local reduction in the cross-sectional area. The stress intensity at this point is then higher than in the rest of the bar, which has not yet yielded. If it were not for the work-hardening effect of this slight local deformation, the reduced section would not be able to sustain a load sufficient to deform the remainder of the bar, so the section would continue to reduce and rupture would finally occur at this point, without any general extension of the bar as a whole.

A certain minimum rate of work-hardening is necessary for general extension to take place. Suppose the first local yielding reduces the cross-section of the bar by 1 per cent. Then unless the yield point of the metal is raised slightly more than 1 per cent by this deformation, the reduced section will not be able to sustain even the load which originally caused it to yield, and which was *insufficient* to cause yielding in the remainder of the bar. If the yield point is raised more than 1 per cent, then an increase in load will cause further deformation to occur at some other point in the bar. This process results in general extension, or general elongation.

Usually a stage is reached at which the rate of hardening is not sufficient to shift automatically the location of the yielding. The bar then necks down and breaks.

As long as general extension is taking place, the *load* on the bar must be increasing. When necking begins, the load can no longer increase. It may remain fairly constant for a while and must then decrease. The load per unit area of the reduced section, however, may continue to increase.

The total reduction of area at fracture is thus made up of two parts: (1) A reduction corresponding to the general extension before necking begins; the volume of the metal remains practically constant. (2) A local contraction at the point of fracture.

It will thus be seen that a rapid rate of hardening by deformation favors general extension rather than local reduction of area. Manganese steel is a typical example of a material which shows a high general elongation with little local reduction. It is also characterized by rapid hardening under deformation. Bronze behaves in a similar manner. Brass shows a greater tendency to neck down, but much less so than pure copper, which hardens less rapidly by deformation.

An extreme case is represented by glass at such a temperature that it is fairly soft. Pulling a glass rod in this condition results in a break with practically 100 per cent reduction of area and little general elongation. The glass does not become harder as a result of the deformation. If a hot rod of glass is withdrawn from the source of heat and pulled apart, there is apt to be very high general extension, because the points which are reduced in cross-section strengthen themselves by becoming cooler. If they remained at the same temperature, rupture would occur at the first point to yield and general drawing out would not be possible.

At high temperatures metals somewhat resemble soft glass, since the hardening effect of the deformation is removed by spontaneous annealing. Some annealed copper wires tested at room temperature showed a general elongation of 24.5 per cent with a reduction of area of 76 per cent. When broken at 950 deg. C. at such a rate that rupture occurred in 5 seconds, the elongation was 17 per cent and reduction of area 98 per cent, a considerable increase in reduction of area with a decrease in elongation.

Reduction of area of single crystals tested in the intermediate zone of temperature is very high, approaching in some cases 100 per cent. On the other hand, when there are a small number of grains to the cross-section of a test-piece, conditions appear to be unfavorable for high reduction of area. If the grain size becomes still smaller, the reduction of area increases. Extremely small grain size, such as probably exists in hardened steel, is unfavorable to plasticity of any kind, so that theoretically a point must be reached where further reduction of grain size no longer results in increased reduction of area in the tensile test. This point is apparently not reached in recrystallized metals; ordinarily the reduction of area is greater the smaller the grain size.

Increase in Oil-Refining Capacity

The oil-refining capacity of the United States has increased 813 per cent in 16 years, according to the American Petroleum Institute. The increase has, of course, been brought about largely by the demand created by the internal combustion engine.

In 1906 the refineries of the United States, running to capacity, could handle about 219,000 bbl. of crude petroleum a day. The principal demand was for kerosene. Gasoline was a byproduct and only about 8,000,000 bbl. of it was produced during the entire year.

On Jan. 1 of this year, the refinery capacity was over 2,000,000 bbl. a day. The principal demand is for gasoline which, according to the latest official figures, was produced during July at the rate of about 160,000,000 bbl. a year.

The present refineries in Mexico alone have a capacity nearly as great as the refineries in this country had 16 years ago.

Japanese Pulp Industry

In 1921 there were thirteen Japanese companies, with twenty-eight mills, engaged in the pulp industry, as compared with seventeen companies and thirty-one mills in 1920, according to Trade Commissioner H. A. Butts, Tokyo, to *Commerce Reports*. The total output of pulp amounted to 268,261 tons in 1920 and 250,027 tons in 1921. This decrease was caused, however, by the financial depression in Japan last year. The 1922 output is expected to be 30 per cent greater than that of 1920, and in the near future the Japanese production of pulp will probably exceed 400,000 tons annually.

Modern Practice In Manufacture and Applications of Steamed Ground Wood

The Present Status and Practical Possibilities of This Process of Paper and Board Manufacture—Part I, in Which the Theory of the Process Is Discussed and the Equipment Is Described

By A. O. Bragg

THE SCANDINAVIANS and Germans, and other European paper makers to a smaller extent, have made papers and boards from steamed mechanical pulp alone or with other pulps for over 25 years. In fact, certain kinds of papers made entirely from this material form important lines in their domestic and foreign trade. Fry, in Germany, seems to have been the first to steam wood in the log before grinding and the first to discover that the action is largely one of hydrolysis. Since that time, in 1867, refinements and improvements have been made so that some American mills, even with the higher labor costs, are carrying out the process with success. However, there seems to be a scarcity of information available in the pulp and paper literature regarding modern practice of this kind of ground-wood manufacture, and it is the object of this article to discuss the theoretical considerations on which its economical and effective operation must be based and to detail successful American practice in equipment, operation and applications. In Scandanavia and Germany the practice is to handle the wood by manual labor. Moreover, the equipment used is not particularly adapted to large production. For these reasons, European methods are not applicable here.

Unless the various methods of heat-treating wood with water before grinding are well defined and differentiated, there is likely to be confusion in referring to them, especially in view of the limited practice of this operation in America. Certain literature mentions as a variety of this process the simple soaking of the logs in hot water for a short time for loosening the bark, whereas in purpose and effect it is totally different, in that no appreciable hydrolysis or chemical change is effected in the wood. Such changes are essential to obtain pulp with the characteristics of the true steamed ground-wood pulp. This soaking process is simply a well-known preliminary operation to barking, often carried out to melt ice as well as loosen the bark. Treating logs in boiling water at 212 deg. F. for several hours causes hydrolysis and chemical changes, but to a much smaller degree than those brought about by steaming the wood—the most efficient and practical method for causing such changes.

Tests on Cooked Spruce

Thickens and McNaughton[1] from their extended grinding tests on spruce at the Forest Products Laboratory presented the following summary:

1. Cooking spruce prior to grinding results in a stronger fibered pulp, although at least 25 per cent more power per ton is required than is used for grinding untreated woods. The horsepower consumption per ton when grinding under conditions of varying cylinder pressure decreases to a minimum at approximately 65 lb. pressure on a 14-in. cylinder; this holds for dull or sharp stones.

2. When wood is cooked under conditions of constant pressure and varying lengths of time, the maximum power consumption per ton of pulp is obtained after cooking for 6 hours. This holds true, regardless of the pressure at which the cooking takes place, between zero and 75 lb. pressure.

3. Wood which is cooked at high pressure requires more power per ton of pulp when ground under the same conditions of cylinder pressure, speed and surface of stone than wood which is cooked at lower pressure, if the duration of the cook is the same. Likewise, the production of pulp in 24 hours is materially less when the wood has been cooked at high pressure than if it had been cooked at low pressure.

4. The yield per cord is influenced very greatly by the length of time the cooking is carried on and the pressure of the cook, being much lower for high pressures than for low and also for long cooking periods than for short.

5. The power to the grinder increases with speed and pressure of grinding and decreases with the degree of sharpness of stone. There is also a very slight increase in the power required with increases in temperature, other conditions remaining constant, while the thickness of stock in the grinder pit has almost no influence. Under like conditions of all other factors, the power to the grinder is less for steamed wood than for green or seasoned wood untreated.

6. With a fixed amount of power to the grinder and a fixed grinding pressure, the speed of the pulp stone will vary greatly, depending on the length of time the wood has been steamed and the steaming pressure. Unsteamed wood will grind at low speed, while that steamed a long time will grind at high speed with the same amount of power in the grinder.

7. There is little if any difference in the quality of pulp obtained as a result of using either the boiling or steaming process. The color, length of fiber and yield are practically the same if the boiling or steaming is carried on at the same temperature.

8. The amount of pulp produced in grinding cooked wood with a fixed amount of power to the grinder is less at high pressure and low speed than it is at low pressure and high speed. This results in a greater horsepower consumption per ton of pulp at high pressure and low speed.

Steaming Versus Boiling

It will be noted (paragraph 7) that similar results are obtained either by boiling or steaming the logs, at the same temperature. For practical reasons, steaming is practiced almost to the exclusion of boiling. In the first place, whether the water be added to the cooker already heated to 212 deg. F., or added cold and then heated in the cooker, much steam must be wasted in either case in heating it. In cooking with steam alone, its heat is given up directly to bringing the logs to its

[1]Bulletin 343, U. S. Department of Agriculture, 1916.

temperature. Secondly, while the steam left in the boiler after steaming can be blown off and its heat reclaimed by absorbing in boiler feed water, the water remaining from the boiling process is too contaminated with acids and dissolved matter to permit its being used for steam generation by the power plant. While it is possible to save hot water from a boiling and use it for the next batch, this involves expense for pumping and mechanical complications which makes the scheme too expensive.

The Enge and Bache-Wiig methods (see below) involve the use of auxiliary vacuum and compressing machinery which adds to the cost from investment, power, maintenance, labor and the low mechanical efficiency of vacuum and compressing machinery. However, these inventors claim to produce white or natural-colored ground wood. If the increase in strength effected in the pulp by these methods is comparable with that produced by simply steaming the wood, the extra cost would be to a large extent compensated, though in installing these or any other kind of ground-wood treating methods, all the pertinent factors would have to be considered. It will be evident that as a practical and economical mill proposition, the steaming is much superior to the boiling method.

Theory of the Process

When wood is treated in water, either as steam or in the liquid state, at temperatures of 212 deg. F. or over, several effects are produced more or less simultaneously. These include partial solution of the water-soluble materials, organic acids, alcohol, gums, mucilage, sugars, tannin, etc., amounting to 4.83 per cent in spruce and 1.88 per cent in yellow birch (Griffin and Little), and the softening into a gelatinous, adhesive condition of the remaining gums and mucilages. Hydrolysis by the water of the lignine components of the wood, aided by the organic acids liberated, also takes place, which in fact is the action described in Fry's patent referred to above. This hydrolysis is only partial and its extent is determined by the reverse reaction which is aided by oxidation. This oxidation, which occurs along with the hydrolysis, not only slows up and finally stops it but produces the brown color characteristic of the pulp. These coloring matters would be rendered soluble in the sulphite process and would not discolor the pulp, but with steaming alone they are not removed and cannot be removed subsequently without injury to the wood and excessive loss.

These reactions, with the rosin and pitch removal and the temperature actions noted below, cause a loosening of the fibers in the wood structure, so that the stones do not disintegrate them so much. That is, the grinding is more an action of shredding and pulling the fibers from the wood in more nearly their original length, and less of cutting them out of the wood as in the grinding of untreated wood. This greater average length of fibers and their greater pliability caused by the softening effect, the smaller amount of wood flour and torn pieces of fiber formed, together with the cementing effect of the gelatinized incrusting matter—gums, mucilage, etc.—give the pulp its unusual toughness and tensile strength.

Steaming, carried far enough, will entirely remove the rosin and pitch from even the most resinous and pitchy woods, such as Southern pines, jack pine and balsam fir; whereas if such woods are simply boiled in water at atmospheric pressures or are understeamed, much will still remain in them and cause trouble by clogging the paper machine wire. Rosin is now being completely eliminated from scrub pine and white pine by steaming for 9 to 16 hours at 13 to 20 lb. pressure according to the moisture content of the wood. During these cooks there is a pronounced resinous odor present, especially when a charge is dumped and steam escapes. Rosin softens at 212 deg. F. and melts at 307 deg., while steam at 13 to 20 lb. gage ranges from about 250 to 260 deg. F. After steaming, the logs are found to be split and cracked lengthwise. Considering these facts and the insolubility of rosin in water or organic acids, it would seem that at these temperatures all or part of the rosin must be hydrolyzed by the steam, perhaps assisted by the organic acids liberated, the product obtained from this reaction being volatile at these temperatures. It would seem, furthermore, that rosin, softening at 212 deg. F., would be sufficiently softened at 250 to 260 deg. F. to seep out of the wood through the seams and cracks which are opened up by the heating. Moreover, these openings probably permit much more penetration of the steam and thus expedite the reactions, no matter what wood is being treated. Experience proves that boiling the wood at 212 deg. F. (atmospheric pressure) will not remove the rosin and pitch, and understeaming does not permit complete penetration of the steam, so that some rosin still remains in the wood.

Another factor seems to be of great and even fundamental importance. This is the density of the wood, in weight of bone dry wood per cubic foot. On this basis, the density is, of course, independent of the greenness or dryness of the wood and is practically a constant for any given species. The necessity for careful consideration of the density of the wood steamed will be evident from the citation of an actual experience which came under the writer's observation.

Importance of Density

It was desired to discover the most effective steam pressure and cooking period to apply to loblolly pine in order to eliminate all rosin and obtain an extremely tough board. Certain of the Southern pines are being successfully steamed commercially for 9 to 16 hours at 12 to 20 lb. pressure, but the species cooked are unknown; in fact in this case it is not known whether one or more than one species are used. The best that could be done, therefore, was to treat the wood under the same conditions in expectation of obtaining similar pulp. However, after so treating a carload of the supposed loblolly pine, grinding and making into laps, instead of the strong brown pulp desired, a comparatively weak, brittle, reddish-cream colored pulp in which there was still much rosin was obtained.

A compilation of the densities of the different Southern pines from the data of the Forest Products Laboratory showed that they varied widely as follows:

	Density, Lb. Per Cu.Ft.
Loblolly pine (*Pinus tæda*)	30
Longleaf pine (*Pinus palustris*)	34
Pitch pine (*Pinus rigida*)	29
Scrub pine (*Pinus virginiana*)	26
White pine (*Pinus strobus*)	22

Considering that good results are being obtained by steaming "Southern pine" under the above conditions and that their duplication on loblolly pine failed to give the same quality of pulp, the only explanation is that the wood alone must have caused the divergence in

results and that the same species of wood was not used in both cases. The wood tested experimentally weighed 4,800 lb. per cord and had a density of 28.45 lb. per cu.ft., which, allowing for the probable better sampling by the Forest Products Laboratory in its determinations, corresponds to the density of pitch pine instead of loblolly pine, which it was supposed was being cooked. Moreover, from obtaining such different results from steaming Southern pines of similar moisture contents under similar conditions, it seems logical to attribute this divergence solely to the difference in densities of the woods in the two cases.

Accordingly, it would seem in general that to obtain pulp of the same average fiber length and color, the greater the density of the wood the more drastically must it be cooked, either by an increase in the steam pressure or temperature, or in the time of cooking, the former plan being the more practical. It would seem logical that the heavier and more dense the structure of the wood the higher the steam pressure necessary to effect penetration, expand it and open up seams and cracks, thus permitting complete action of the steam and temperature on all parts of the interior of the logs and also the escape of volatile and softened matter. It is the writer's opinion that woods of about 27 or 28 lb. per cu.ft. density should be steamed with a minimum of 35 lb. pressure for 20 hours, and higher density woods in proportion.

However, other factors besides the density must be considered in deciding on any cooking policy. Since, like any digestion process, the action takes place in two stages, the greener the wood the more drastic must be the cook for any given species. The first stage is that in which the wood is brought up to steam temperature and the second that in which the actual digestion and chemical changes occur and the steam supplied simply replaces the heat lost by radiation. The large amount of water in green wood must be heated up to steam temperature before any hydrolysis takes place, and this consumes time and steam. The moisture content of the wood can be regulated to some extent by felling it in the fall when sap is down and letting it season thoroughly before use.

Equipment

Wood Room

Nothing unusual is necessary in the way of wood-preparing equipment, any standard machinery for cutting the wood into 2-ft. lengths being used. This machinery should preferably be on the same floor level as the rotary boilers when these are used, or as near the top of vertical digesters as possible, to reduce power and investment required for conveying and elevating wood. Barkers may or may not be required according to conditions. See "Operation."

Steamers, or Digestors, and Conveyors

Two types of steamers are used commercially in America—the spherical rotary boilers such as are used for rag boiling, and stationary vertical cast-iron cookers. All digestors to be used for pressures over 20 lb. gage should be constructed according to the requirements of the A.S.M.E. Steam Boiler Code, be inspected regularly and preferably insured. In any case where it is desired to operate grinders continuously on steamed-wood logs, two steamers should be installed for the following reasons: First, to have one steamer in reserve in case of breakdown; second, to permit of continuous operation of the grinders by compensating for the long time needed for cooking one charge and thus keeping the grinders supplied with wood. Two cookers of either type described below will be ample to keep two three-pocket grinders supplied for a cooking period of 15 to 20 hours, which is long enough for most requirements. Finally, by using two cookers, the steam left after a cook can be utilized by blowing it down into boiler feed water before discharging the wood; whereas with only one steamer the delay involved makes it uneconomical.

Rotaries are best mounted on concrete piers and as closely together as possible to economize space and simplify the wood-conveying equipment layout. Too small foundations are false economy in this case, because, during the rotation of a boiler when filled with logs, severe and sudden stresses are set up by piles of logs clinging together during part of a revolution and suddenly becoming loosened. Fig. 1 is an elevation of a good layout for two rotary boilers showing the uncooked wood conveyors to grinders. Fig. 2 is a vertical section through the boilers and discharge pit. This arrangement is particularly adapted to installations where space is limited and the use of water canals to grinders is impracticable. It will be understood of course that canals may be substituted for the cooked-wood handling arrangement shown and vice versa.

The whole equipment occupies a space of approximately 40 by 21 by 25 ft. high. The boilers are 16 ft. in diameter and each will hold about 6 cords of rough wood or 7½ cords of peeled wood, as irregularly discharged into them from the conveyor and not as carefully packed. They are placed over the steamed-wood discharge pit and can be rotated once every 4 minutes by a vertical worm which engages a circular rack fastened around them, as shown. Lining, while desirable, is not absolutely necessary, as the small amount of corrosion is extremely slow if all rivet holes and joints are kept calked. Each cooker has a manhole about 2x3 ft. for filling, emptying and permitting interior repairs and is also provided with a small bleeding pipe and valve for removing condensate and relieving air while heating up. In common with all rotary boilers, steam enters through the hollow shaft after passing through a reducing valve.

The 2-ft. logs from the wood room are carried by a

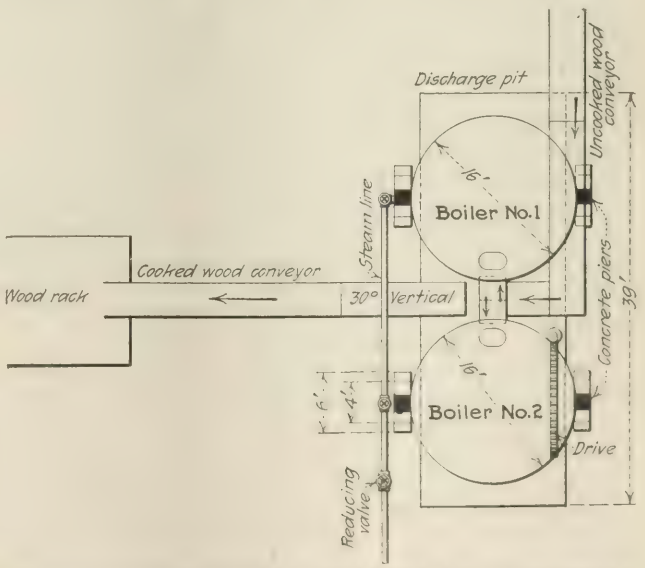

FIG. 1—PLAN OF ROTARY STEAMERS AND CONVEYORS

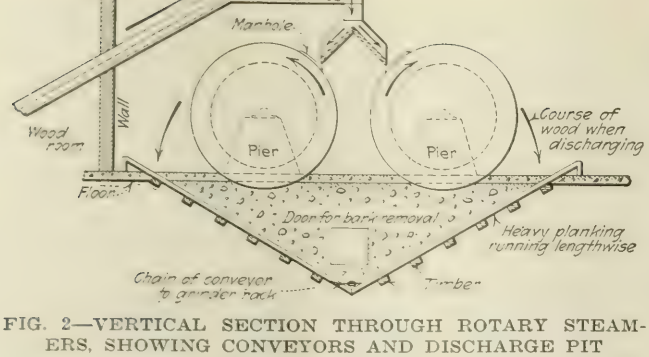

FIG. 2—VERTICAL SECTION THROUGH ROTARY STEAMERS, SHOWING CONVEYORS AND DISCHARGE PIT

chain trough conveyor at approximately a 45 deg. vertical angle to the level conveyor section over the boilers, which discharges into a chute above and between the two boilers, which in turn discharges at will into either of two smaller chutes directly into the manhole of the boiler being filled.

A Triplex block is used for handling the manhole cover, while a system of stairs and runways permits access to all parts of the filling system. Upon falling from the manhole in emptying a boiler, the wood drops into a steamed-wood discharge pit located beneath the two boilers (Fig. 2). The wood tends to roll down to the middle point, where it is put on a chain conveyor, which takes it to the grinders. This conveyor drops the wood into a wooden rack, a fenced-off portion of which is used as storage.

In general, rotary boilers have the advantage that, because of their shape and the closeness with which they may be placed together, they can be erected in some empty corner of a wood room or grinder room, as they do not require the heavy foundations and tall buildings necessary with vertical steamers. Moreover, they can be used very effectively as a drum barker, by rotating after steaming is completed, thereby softening and loosening the bark. Wood for the vertical type must be barked previously unless it is to be ground in the rough. The vertical type requires less calking and attention to keep tight and the maintenance cost is much less than with the rotary, in which the joints are loosened by the movement. The stationary type can be effectively lagged with heat-insulating material to reduce radiation and steam consumption to a minimum, while a rotary is difficult to keep properly lagged. A stationary cooker dumps practically instantaneously, while about an hour is required to empty 7 cords out of the manhole of a rotary. For this reason the daily production from two digestors of equal volume is slightly more with one of the vertical design, though by using a rotary as a drum barker the heavy losses in knife-barking wood are avoided. Taking everything into consideration, it would seem that, while each type offers advantages for particular conditions, in general the best and cheapest installation to operate is the combination of vertical, stationary steamers with drum barkers when barking must be done.

A good arrangement for vertical cookers is shown in Fig. 3, which adopts some features of sulphite digestor towers. The wood bin consists of very heavy planking on steel I-beams, and inside has heavy steel plates on which the logs strike when falling from the conveyor. The wood, in 2-ft. lengths, is dropped into the cookers through trap doors, operated from a distance by a lever system to prevent injury to the workmen. The steamers are supported, as shown, on three legs, which rest on the concrete floor of the discharge pit. This is kept filled with water, except when emptied to clean out, and connects by an underground canal to the grinder feeder canals. The bottom of the cookers is conical in shape so that all the wood will fall out when the bottom is lowered by the action of a hydraulic ram on the floor beneath, whereby a tight joint is normally maintained.

These cookers are now made of cast iron, tested for 50 lb. working pressure, and have 1½-in. walls to compensate for the slow chemical deterioration and the mechanical wear from the logs. They are made up of four cylindrical sections superimposed upon one another, and a top dome-shaped section bolted together with the proper gasket. The cost of a digestor is about $5,000.

The manhole cover is provided with a ring for handling with a chain block and is fastened down by lag bolts to the dome-shaped top section. This dome-shaped section has a boss in it which may be drilled out if desired for the insertion of a thermometer.

The log conveyor over the wood storage bin has a baffle, so arranged that it can be put in position and cause the logs to fall over the first cooker, or left open, permitting the logs to discharge over the second.

The unit log capacity of rotary and stationary digestors—i.e., the cubic feet of digestor volume required

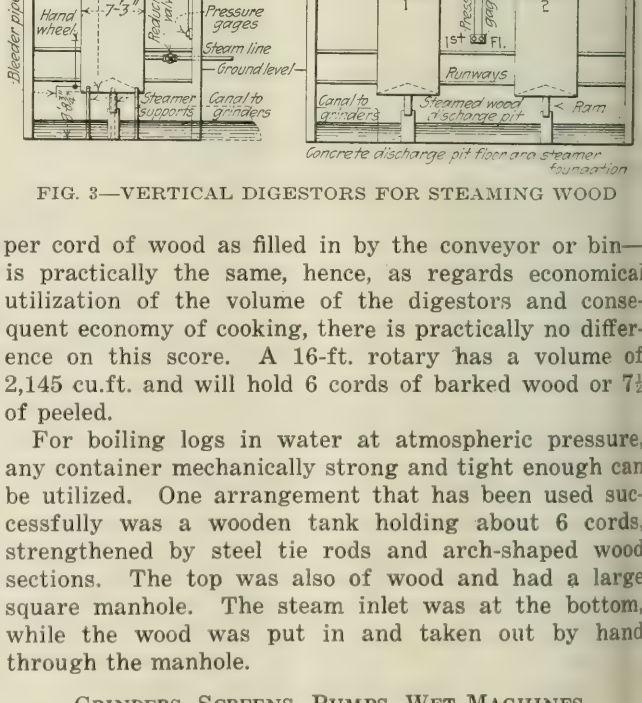

FIG. 3—VERTICAL DIGESTORS FOR STEAMING WOOD

per cord of wood as filled in by the conveyor or bin—is practically the same, hence, as regards economical utilization of the volume of the digestors and consequent economy of cooking, there is practically no difference on this score. A 16-ft. rotary has a volume of 2,145 cu.ft. and will hold 6 cords of barked wood or 7½ of peeled.

For boiling logs in water at atmospheric pressure, any container mechanically strong and tight enough can be utilized. One arrangement that has been used successfully was a wooden tank holding about 6 cords, strengthened by steel tie rods and arch-shaped wood sections. The top was also of wood and had a large square manhole. The steam inlet was at the bottom, while the wood was put in and taken out by hand through the manhole.

GRINDERS, SCREENS, PUMPS, WET MACHINES

Some mills make no provision for corrosion during and after grinding, although it is more severe than dur-

ing the cooking, owing to the soluble matter and acids remaining in the logs. The best modern practice is to have all the grinder pockets lined with bronze and to use solid bronze centrifugal pumps, screen plates and wet machine cylinder mold wires. Piping is also preferably of this material, but wood is used with success. Cast-iron valves and fittings have been used, but these corrode considerably.

Because of the slowness of the pulp and its greater fiber length—more on the order of sulphite than the untreated news ground wood—coarser screen plates are required or greater screening surface with finer slots.

Beaters, Jordans

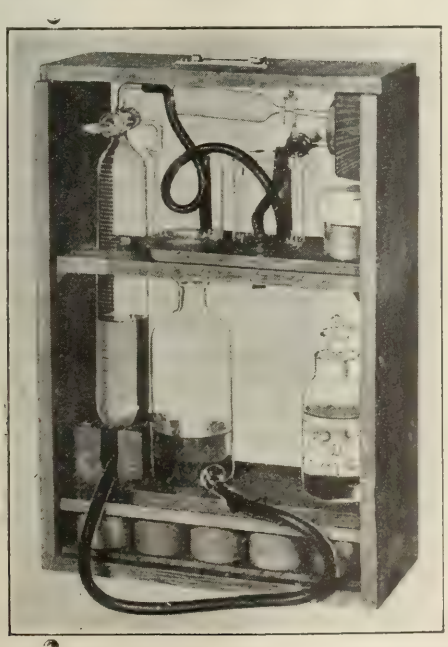
By the time the stock reaches the beaters or mixing tanks and jordans, every trace of acid is washed out so that any standard equipment can be used without modification, bearing in mind that, in common with natural or untreated ground wood, beating cannot materially change it, except to shorten the fibers, once it is ground.

The concluding installment of this article, describing the operation of a modern plant for steamed ground wood, will be published in a subsequent issue.

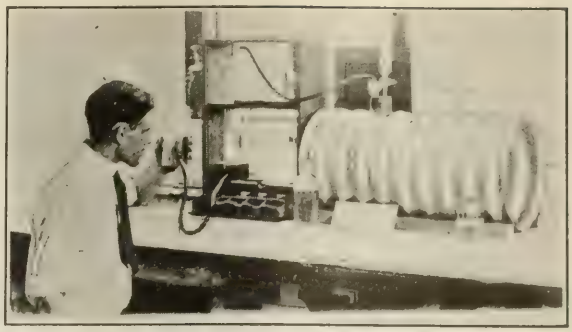
A Testing Device for Weighing Galvanized Coatings

IN PURCHASING galvanized sheet metal and wire for manufacturing various products, the manufacturer's specifications include the weight of spelter coating in ounces per sq.ft. An interesting device for measuring this spelter has been developed recently and may be used in the laboratory as well as in the field. The device determines the weight of galvanized coating on a unit area regardless of any convolutions or corrugations.

The weight determination is based on the action of hydrochloric acid on the galvanized coating, collecting and measuring the hydrogen gas evolved. By using differently shaped rings, which are shaped to fit the surface to be tested, the weight of coating is determined on flat sheets or formed culverts. Wire coating is determined by placing a definite length of wire on a glass plate under the flat ring. The rings are made to resist acid, nickel or tinned iron being used. The rings are fitted with three-hole stoppers. One hole carries the filling tube provided with a glass stopcock, while the other holes carry exit tubes. For collecting and measuring the hydrogen evolved, a measuring burette and leveling bottle are used.



THE TESTING DEVICE PACKED IN ITS CASE



THE APPARATUS IN USE

How the Determination Is Made

To make a determination the proper ring is sealed to the surface to be tested with acid-resistant cement. The leveling bottle, glass burette, tubes and ring are filled with water by manipulating the leveling bottle and stopcock. About 30 c.c. of concentrated hydrochloric acid is then placed in the filling tube and about 5 c.c. admitted to the ring. When the liberation of gas ceases the apparatus is rid of gas by filling the ring and connecting tube with water, thus forcing all the gas into the burette.

The number of cubic centimeters of hydrogen measured at 20 deg. C. multiplied by the factor provided with each ring gives the ounces of spelter coating per sq.ft. of actual surface on one side of the culvert.

Improved Heroult Furnace

A 7-ton basic Heroult furnace has been installed by the American Bridge Co. in the International Nickel Co.'s new plant at Huntington, W. Va., to melt Monel metal.[1] It has a round shell and flat bottom—a combination of great structural strength. It tilts both front and back on rockers; both rocker and track are curved. This does away with the counterweights necessary for the hinged type, it permits the furnace to be set lower than though the track was curved, and the center of gravity can never go above the rolling center.

Large copper pipes act as current conductors. Since this form is the best for carrying alternating current, and permits of water cooling, the amount of copper necessary is reduced two-thirds. Cooling water passes through the transformer, then by the conductor pipes to the electrode holders, through flexible connectors to electrode coolers, and thence to waste. Another unique feature is the placement of the electrical apparatus in a room immediately under the furnace.

The three electrodes are held by stiff cantilever jib cranes whose masts are quite short and operate in guides attached to the side of the furnace shell. In general, the design is very compact, requiring the minimum of headroom.

Furthermore, there are no flexible cables obstructing the surroundings.

Petroleum Asphalts in the Roofing and Waterproofing Industries

By Dozier Finley
Director of Technical Research, The Paraffine Companies, Inc.

Development of the Use of Petroleum Asphalts in Roofing and Waterproofing Industries—How This Material Is Used in Making the Various Types of Commercial Product Is Described

IT IS IMPOSSIBLE for this topic to be treated properly from the point of view of the experience of any one person who is connected with the roofing and waterproofing industries. The history of these industries spans more years than are comprehended in the active business or professional life of any individual. However, the existence of some of the companies operating in this field extends back so far they may be said to have been present at practically the birth of the industry; their records afford valuable data on the subject.

Development and research in waterproofing and roofing manufacture lie largely in the selection and combining of ingredients and components and in the seeking for and development of new raw materials.

Development Through Use of Coal Tar

As the industries existed prior to 1885 most of the work revolved around the use of coal tar. For roof work it was found that certain coal tars were adapted to the laying of comparatively flat roofs; one or more layers of paper or felt were applied to the roof by means of pitch produced by a partial distillation of the coal tar; a surfacing of the tar pitch was given to the paper layers and into this surfacing was sprinkled gravel, shells or similar granular material. Much of the tar was not satisfactory for such roof work and various devices for improving its quality were practiced, as, for instance, heating it with lime or with wood or coal ashes.

Admixtures with a large range of other materials were tried and even used to a considerable extent; for such blendings were used rosin, pine tar, tallow, "pitch," asphaltum, dead oil and, in fact, anything which showed any tendency to mix with the tar when cold or when heated. Aside from tar, fabrics saturated with linseed oil, with other oils or with oils and gums combined, were proposed for roofing. Many roofing mixtures were designed to be spread like mastic without the support of a paper or fabric, apparently with the childlike faith that the elasticitiy of the coating so formed would respond to every movement of expansion and contraction on the part of the sheathing boards.

Failings of Early Products

Viewed in the light of present-day knowledge, the things which the inventors and manufacturers before the early '80s did not attain were:

1. The manufacture of standardized bituminous roofing and waterproofing materials in large quantities.
2. The manufacture of prepared or ready-to-lay roofing in a form and weight convenient for marketing, with a substantial weather-resisting coating and adapted to being laid on flat areas, on slopes and even on vertical surfaces, and possible of use under any condition of climate from torrid to frigid.
3. The manufacture of bituminous roofing materials of attractive appearance to compare in artistic value to slate, shingles or tile.

Along with this, of course, was a lack of proper mechanical appliances to manufacture roofing and waterproofing materials in the vast quantities used today. This, naturally, is not strange, since growth in any industry brings with it the development of machinery of greater capacity and lower unit cost of operation.

Generally speaking, the development of these industries has been seemingly slow; this may be ascribed to two reasons: First, the tardy discovery and slow recognition of suitable raw materials; and secondly, the inability to predict accurately the durability of any particular combination of materials; a new or improved product has had to pass through a long period of service test before the manufacturer, the dealer and the consumer, each in turn, have been convinced of its merit.

It is true that some opposition has been brought to bear on these industries. Metal roofings, shingles, slate and tile have been in competition with bituminous roofing. Soap compounds mixed with concrete, surface treatment of masonry walls, and structural devices have been used instead of bituminous waterproofing and methods. The engineering world and the general user, however, have always given due recognition to the merit of the bituminous products. As a result these materials have established a definite and not unimportant place for themselves in modern building and engineering.

What Bituminous Roofing and Waterproofing Are

Strictly speaking, the term "bituminous roofing" is limited to the well-known types of ready-to-lay roofings either in roll or shingle form and to built-up roofs of several plies of roofing felt cemented together with bituminous material. Associated with these roofings are certain related products such as bituminous roof paints and bituminous plastic compounds used for maintaining roofs of this type.

"Waterproofing" is accomplished by a variety of materials and methods. Layers of felt may be cemented together to form a water-resisting dam or membrane not dissimilar to a built-up roof; paints or combinations of paint and coatings of bituminous compounds applied in heated condition are often used on walls or under floors to exclude water; bituminous materials have been used in the form of an emulsion mixed with concrete; between the separate elements of large structures, such as dams, asphaltic compounds are often poured in masses; a modification of this last use, in part a waterproofing method, is the use of asphalts or asphaltic materials for the expansion joints of concrete highways; a limited type of waterproofing, really a dampproofing, is accomplished by using saturated felts, or saturated and coated papers, between the walls of buildings—the so-called "building papers."

Application of Petroleum Asphalt to Roofings

A retrospect of this entire field might be expected to reveal a single definite "line of descent" along which

ll development proceeded. Following closely the commercial and manufacturing history of the industry, it s an impressive fact that its growth has held absolute ace with the advance made in the production of petroeum asphalts. A certain production of roofing may e claimed to have followed the increased output of natural" asphalts, and it is true, without question, a arge development of coal-tar roofing materials has ccompanied the growth of the coke-oven industry and he more careful collection and marketing of gas tars. But it remains a fact that the constantly growing roduction of the most widely adopted types of roofing as been in strict correspondence with the production, or general purposes, of residual asphalt from the disillation and treatment of petroleum.

The first commercial productions of asphalt from etroleum were from California oils, which yielded asphalt as a normal product of distillation. Asphalt from he oils of Pennsylvania, Ohio and Indiana was practically unknown until well into the twentieth century; hen it was produced by methods of treatment apparently unknown to the earlier refiners—it was produced by what might be termed abnormal processes rather han the old, and previously well-known, methods of listillation.

The first application of California asphalt to the manufacture of ready-to-lay roofings was made by Truman J. Pearce and Melvin W. Beardsley as set forth in the patent granted them Sept. 14, 1886. From a historical point of view it is unfortunate Pearce and Beardsley did not more specifically state in their application that they preferred to use a "maltha" which was the residue of petroleum distillation. However, at the time their work was in progress many "natural" asphalts containing much mineral matter were obtainable in California. To these early inventors it seemed possible to use these interchangably with asphalt produced from petroleum. Indeed, the apparently limited possibilities of the then known petroleum territory in California and the seemingly extensive natural asphalt deposits possibly inclined them to the use of the natural product.

But, as might be expected, when asphalt from petroleum distillation outstripped the quarried material, Pearce and Beardsley, or rather the Paraffine Paint Co., which manufactured under their patents, fixed on the material which could be obtained in larger quantity and of more uniform quality and greater purity.

Work of Pearce and Beardsley

Pearce and Beardsley employed the residual asphalt as a saturant for burlap which then was given a further coating of a firmer asphalt; to the back of the coated fabric, while the coating was hot and adhesive, was affixed a layer of paper or felt to give the roofing stiffness during handling and shipment and also to afford additional waterproofness. Probably this was the first distinctly successful ready-to-lay roofing which had been produced. It established records of service reaching well beyond 20 years, in many instances with the material exposed on slopes so steep as to draw forth a dogmatic "it can't be done" from the roofers of that day. It became a practice to supply this roofing without change of formula to the coldest climates of the North and to the hottest parts of Arizona and Mexico. No limits were placed on the angle of the slope to be covered, no matter what the sun heat might be.

Large quantities of the roofing were readily sold to the smelter plants in Arizona and Montana—two extremes of climate, but in both involving an exposure to acid fumes so corrosive that the paint and the very nails were eaten from the boarding of the buildings. The service rendered by the roofing under such conditions is well illustrated by a letter received over 20 years ago from the United Verde Copper Co., Jerome, Ariz., telling of a sagged portion of roof on which condensed exhaust steam, flue dust and dissolved fumes had combined into a little lake of highly concentrated acidity; though this condition had obtained over a period of several years, the roofing had not leaked a single drop. One of the most successful large pieces of work carried out with roofing made according to this plan was the covering of the entire Midwinter Exposition at San Francisco in 1893-4.

Substitutes for California Petroleum Asphalt

So successful was the roofing made from California petroleum asphalts that the Standard Paint Co. of New York, under the instructions of Beardsley, began the manufacture of similar roofing in the East. Petroleum residuum of quality similar to California asphalt was not obtainable in the East and it was necessary to bring material from the Pacific coast. However, William Griscom, of the Standard Paint Co., hit on the scheme of using the residual products of Eastern petroleums in conjunction with very thick sheets of felts. In this way a very large portion of Eastern residuum tempered with rosin could be used as a saturant; the saturated sheet was given a coating which consisted of a California asphalt blended with a large measure of weather-resisting gums and pitches.

Thus was produced in the East the first successful, standardized, ready-to-lay roofing made in large part from Eastern materials. It came almost at once into great popularity, which it retains to the present day. Its name, "Ruberoid," was caught up by the public and applied as a type name to all ready-to-lay roofings regardless of the manufacturer's name or any other relationship to the original in manufacture, formula or even appearance.

It is now recognized that the materials which are best adapted to the manufacture of ready-to-lay roofings must conform in a great measure to the standards established by the early work of Pearce and Beardsley in California. Of course the developments which have taken place in the last 20 years in the processes of oil refining and asphalt making have been reflected in the improved quality of the asphalts and the products made from them; the roofings made today will withstand conditions of exposure which would not have been possible for roofing made from the original petroleum asphalts, though this does not gainsay the very excellent quality of the roof coverings made with the earlier types of California asphalts.

The oils of Ohio and Indiana, and later the oils of Kansas and successively those of Texas, Oklahoma and Mexico, have been made to yield asphalt. Originally oils such as those from Ohio were supposed to be incapable of giving asphalt in the refining process. In those days refining consisted essentially of heating the oil in closed containers, or stills, and thereby driving off the volatile portions, the temperature being gradually raised till the distillate had attained a high boiling point and the residue in the still had been reduced to a coke, or, in the case of asphalt-yielding oils, to an asphalt of the desired hardness. Steam was admitted

at the latter part of the distillation to reduce the vapor pressure or, in the language of the stillman, "to carry the vapor over."

Obtaining Asphalt From Paraffine Base Oil

F. X. Byerley obtained a patent in 1894 for a process of asphalt proluction which accomplished two things: first, the production of an asphalt from oil and oil residuum which would not yield asphalt under former methods of refining; and secondly, the production of much higher yields of asphalt from oil or residuum which normally yields asphalt. The process is carried out by blowing air through the petroleum residuum at elevated temperatures and is conducted in the ordinary still; a reduced amount of distillate is produced, the greater part of the residuum being converted into asphalt through complex chemical reactions, among which there is certainly an oxidation, as hydrogen is eliminated with the formation of water which appears in the distillate. If the process can be regarded as accomplishing, in a measure, the equivalent oxidation which would otherwise be brought about through a term of weathering, it will be seen that the asphalt oxidized in the still, and refined to the proper consistency for use, has conferred on it something of an immunity from the destructive action of continued oxidation when exposed to the weather.

Many modifications of the original process have been brought about, so that it is now possible not alone to produce asphalt from a nominally non-asphaltic oil and to increase the yield of asphalt from asphaltic oils, but it is even possible for the skilled refiner to make a series of asphalts of widely varying characteristics, though of substantially the same "hardness," from a single crude oil or oil residuum. This contrasts strongly with the possibilities of the old, or "steam run," process, wherein there was practically no control of the character of the product, aside from its "hardness."

The production of standardized asphalts from these widely differing oils is indeed a testimonial to the ability of the refiner. From each of the sources named now comes asphalt which would admirably do the work of the original Pearce and Beardsley process. The California asphalt, at one time alone in filling these requirements, has been improved, as might be expected, by the research work of some of its producers to a point of excellency never conceived by those who first used it in roofings.

Manufacture of Roofing and Waterproofing

The standardization of roofings and waterproofings has really preceded the standardization of the asphalt. At the present day roofing materials are almost exclusively built on a felt base, the burlap base being used in an extremely small volume, relatively speaking. The felt falls into three classes: *rag felt,* composed entirely, or almost entirely, of cotton rags, with a small percentage of wool and usually a small amount of burlap; *asbestos felt,* or paper, composed almost entirely of asbestos fiber with a minor percentage of other fiber and a sizing binder to give strength; and *paper based felt,* used entirely in the cheap grades of roofings and sheathings, containing as high as 70 per cent of waste paper.

The materials entering into the composition of these felts are disintegrated in paper mill beating engines until the ultimate fibers are individually afloat in water, the mass is passed on to a type of paper-making machine adapted to the work; the fibers are here felted, pressed and dried. The finished felt, in large rolls, is transferred to the roofing-making machine; here it is passed through a bath of saturant, squeezed by wringing rolls to remove the excess of saturant, and pressed through another set of rolls which spread on it a bituminous coating of varying thickness according to the purpose intended. Either a dusting of a fine mineral powder is now given the product, making the so-called "smooth surface roofing," or a sprinkling of crushed shale or slate of usually a red or green color is applied to the side designed to be exposed to the weather, making a "slate roofing." This in only "slate" in so far as it is surfaced with a thin layer of mineral particles, which may even be marble or serpentine in some instances; but these particles, no larger than a match head, are so firmly fixed in the bituminous coating that the roofing will last upward of 20 years without apparent deterioration.

Smooth surface roofing is sold in roll form only. The slate roofing may be sold either in roll form or cut into shingles, which again are divided into "individual shingles" and "strip shingles," the latter usually comprising four shingles attached together by a common upper portion. Variant forms of these roofings are sold, as for instance a sand-surfaced roofing, or a mica-surfaced roofing, but their use is secondary, though this does not argue against their quality, which may be excellent if they are made of good materials.

Asbestos Roofings

Asbestos roofings usually are made by cementing together two or more sheets of asphalt-saturated asbestos felt or paper. This may be done in the plant and the product shipped ready to lay; in this event the topmost sheet is often unsaturated, which is productive of a white roof. On the other hand, saturated sheets may be supplied to the contractor and applied by him in a manner similar to "built up" roofs, though asbestos roofs are rarely given a gravel or mineral dressing.

Asphalt-saturated rag felts of various weights are supplied to roofing contractors for laying "asphalt and gravel" roofs. The saturated sheets are cemented together on the roof deck, the topmost sheet receiving a flood coat of the bituminous cementing compound; gravel, crushed slag, crushed brick or other desirable or readily obtainable mineral matter of pea size is imbedded in this flood coat to procure a final finish. Using the proper quality of cementing asphalt, such roofs may be applied on slopes so steep the workmen have to be secured by ropes. In this respect, at least, asphalt-saturated felt cemented by asphalt has an advantage over tar-saturated felt and coal-tar pitch; excellent though "tar roofs" are on flat and slightly sloping roof decks, they cannot compete with asphalt on steep slopes.

Many roofers use, and some manufacturers advocate, one or more layers of smooth surface roofing to be built into a roof of the "asphalt and gravel" type. One sheet of medium weight smooth surface roofing can take the place of two sheets of the heavier grade of asphalt-saturated felt. As a better and stronger felt with a greater percentage of saturation is used in the smooth surface roofing, the resultant roof naturally has an enhanced value. Gravel or like matter is usually used as final finish as on the parent type of roof.

It is interesting to note the built-up roof of asphalt-saturated rag felt, or roofing, as above described, has a

degree of fire resistance which places it on an equal basis with asphalt-saturated asbestos roofings.

Asphalt in Waterproofing

The standardization of roofing materials did much to standardize asphaltic waterproofing. The asphalt felt of the roofing industry became the basis for felt for building membranes of several felt layers around the walls and in the floor of the structure to be protected from the entry or exit of water. Modifications have been made as, for instance, the surfacing of the waterproofing fabric with wood flour instead of fine mineral matter in the case of coated fabrics—a change made to obtain better adhesion of the cementing medium.

Asphaltic building papers of three types were developed along with the several types of roofings; these were: paper saturated with asphalt, paper coated with asphalt and paper both saturated and coated. Such papers were designed to prevent entry of moisture and drafts through walls and floors of buildings. Both asphaltic roofings and these buildings papers were made, generally speaking, by the same manufacturers; indeed, in small plants, often on the same machine. To the three above is now added a light saturated felt. The four types are standard with many manufacturers and may be obtained at retail in almost any town in this country in a variety of weights and qualities at, of course, prices in accord with their respective values. They are all superior to that cheapest form of so-called "building paper" known as "rosin-sized sheathing" of a red, gray or greenish color and made of the cheapest grade of waste paper, reworked and waterproofed more by title than in fact.

Asphalt in Paints

Bituminous paints and compounds to be applied in molten condition for damp-proofing and waterproofing have come to the distinctive position of having been the subject of tentative specifications by the American Society for Testing Materials. Treatment of expansion joints in concrete highways also is subject to fairly definite specification by the engineering departments in charge; materials and methods vary from prepared products marketed in strip form to asphalt which may be poured into the open joint.

Bituminous emulsions for waterproofing concrete have been on the market for several years. In general it would seem that a water emulsion of asphalt is an extremely interesting product—emulsification with water makes an asphalt mobile without application of heat at the time of use, and also avoids the hazard attached to bituminous paint with volatile, flammable solvents; the evaporation of the water, which takes only a short time, brings about a breaking of the emulsion and a deposit of the asphalt in a form little different from that obtained through the use of an actual solvent or through hot application.

In waterproofing, where exposure to the weather is not involved, where the waterproofing material may be below grade (and hence at a fairly uniform temperature) and where there may be little vibration of the structure, coal tar is a strong rival of asphalt. The coal tar, of course, is used in conjunction with a tar-saturated felt when the work involves the use of felt.

Grades of Asphalt Used

The type or grade of asphalt most generally used in all this work takes its origin from the old California "D" grade, this was the grade used by Pearce and Beardsley in their work. Without the use of testing instruments the grading of this asphalt was never accurate; in the early days of refining in California the usual test was that of chewing a small portion. Pearce and Beardsley used in their roofing a "D" asphalt which offered considerable resistance to chewing but which would not crumble in the mouth. Samples of this examined since the advent of testing instruments and standard testing methods give a penetration of about 15 at 77 deg. F. and a melting point—i.e., softening point—of about 150 deg. F., both by the methods of the American Society for Testing Materials, standards 1921.

Improvements in refining now permit of the use of asphalts somewhat softer at ordinary temperatures—they offer little resistance to chewing. The penetration will range from 12 to possibly 45 according to the properties of the material itself, as defined by source and preparation, with melting points from 150 to 225 deg. F. or occasionally higher. Most manufacturers of roofings set narrow limits between which their compounds must test—these, except for saturants, are between the limits here given in practically every case. Many manufacturers of roofings also blend the asphalt with fatty acid pitches, natural asphalts, mineral fillers, etc., to obtain increased weather resistance, to economize in the use of asphalt or for other reasons of minor importance.

Of course other tests than melting point and penetration are applied to asphalts. These include volatility, hardening under heat, ductility, ash, solubility in carbon bisulphide, penetration at other temperatures than 77 deg. F., flash point and others less frequently applied.

How Other Grades May Be Utilized

Nor can it be considered that asphalts falling within the ranges above given will accomplish all the things set forth in this article. Asphalts within those ranges form, as it were, the backbone of the asphaltic roofing and waterproofing industries, but much of the work herein described would have to be accomplished through the fluxing, or softening, of an asphalt falling within the above given range, an operation easy of accomplishment. Softer asphalts ranging down even to a stiff, practically liquid material are to be had on the market. These are used for saturants for felts or for fluxing harder grades.

Hard asphalts—so hard they will be powdered in the chewing test—are necessary for other work; while their melting points may not be materially higher than the highest of the medium hard asphalts, their penetration may be as low as 2. They are used in paint making, in the glaze coating of building papers and may be used in compounding roofing coatings to counteract the effect of softer constituents such as soft fatty acid pitches, soft asphalts, etc. It is of interest to note Pearce and Beardsley prior to 1890 used "B" and "C" California asphalt for the making of "P & B" paint and "P & B" building paper—the "B" and "C" asphalts having penetrations of about 3 and 8 and melting points of about 195 deg. F. and 175 deg. F., respectively.

Place of Natural Asphalts and Coal Tar

It would be unfair for the asphaltic roofing and waterproofing industries to fail to acknowledge the immense value of the contributions which have been made to them from the field of mined asphalts. Without question the industries started with those asphalts as

their only raw materials of asphaltic nature, and have used large quantities down to the present date—gilsonite, grahamite and wurtzilite, in addition to the true native asphalt of the medium grade of hardness and associated very often with large percentages of mineral matter. Also these industries owe much to the coal-tar industry, which has been a helpful rather than a harmful rival, and to the asphalt-paving industry, which has been untiring in the development of new sources of raw material and has contributed much scientific data to the entire subject.

The amount of asphalt this country consumes in roofing and waterproofing is not easy to estimate, as it is difficult to separate it from the figures giving total importation and production. It is not amiss to say, however, that the amount has grown in the last 30 years from a few hundred tons per year to well over a quarter of a million tons.

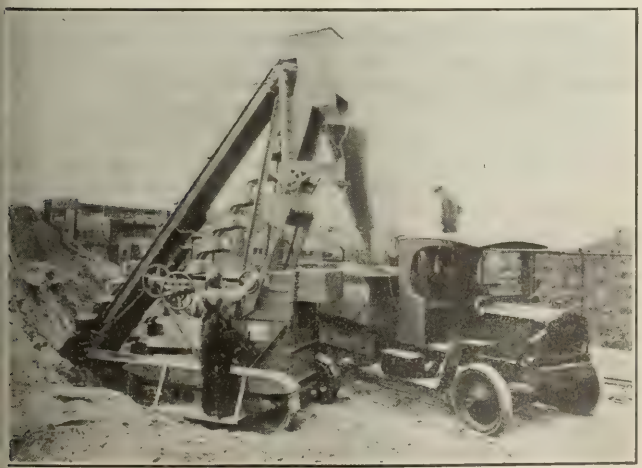
A New Portable Loader

In many plants where it is necessary to handle sand, gravel, crushed stone, coal, coke, cinders, slag and other loose material from ground storage, the portable loader has found wide use. This extended use and the interest shown by many who do not as yet use this machine has been the cause of bringing forward many improved types during the last few years. The latest of these, shown in the accompanying illustration, is called the "Tanktred" and is manufactured by the Jeffrey Manufacturing Co., of Columbus, Ohio.

Among the advantages claimed for this loader attention is called to the fact that the foot of the elevator is so constructed that the buckets are wider than any other part, so that the whole machine can be advanced several feet into the pile with nothing but the clean cutting edge of the buckets coming in contact with the material. For this reason the loader will handle fairly hard material which will not flow.

Another advantage claimed for this loader is a relatively large foot wheel, which, by reducing the centrifugal force, enables the buckets to pick up the material and especially the large lumps without kicking them away. A flexible wood boom keeps the buckets digging, but will spring enough to release them from overload strain when they encounter a cave-in or an obstruction.

Two speeds, a traveling speed for moving the machine from place to place, and a feeding speed for driving the machine directly into the pile, give a wide flexibility of operation.



NEW PORTABLE LOADER

As a result of these various features of design and construction the operator, the only man required in connection with the operation of the loader, can readily manage his machine so that the buckets are always full.

Hair Cracks

During the war many alloy steel forgings were discarded because of "hair cracks" (Fig. 1) usually about ½ to ¾ in. long, a few thousandths deep and almost zero thickness. They are rarely found singly, and if machined off by a fine cut, more will usually be found in new positions.

Dr. Leslie Aitchison[1] believes that they are relics of very small contraction cavities in the original ingot.

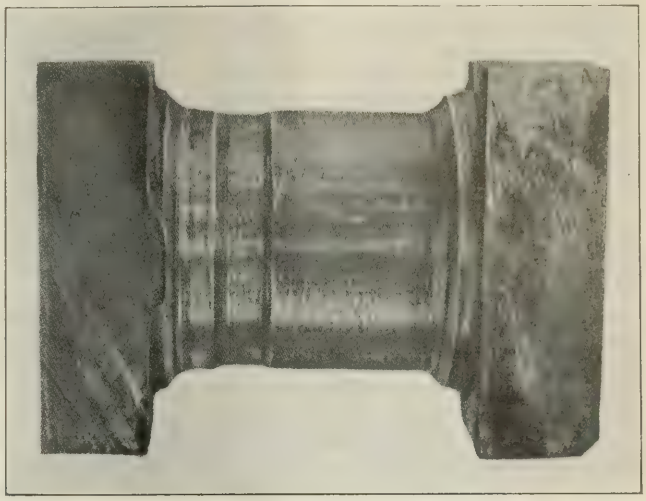


FIG. 1. HAIR CRACKS APPEARING AS HORIZONTAL FINE WHITE LINES IN CENTER OF PARTLY FINISHED CRANKSHAFT JOURNAL

Correct forgings welds these up to some extent, but the utmost care should be exercised during steel making and ingot pouring to reduce the number of contraction cavities to a minimum. Also, the part of the ingot which shows the defect most markedly should be cropped.

While it is impossible to say whether these tiny flaws are harmful to such a thing as an airplane crankshaft, "it is fairly certain that they are practically harmless unless they occur in very vital parts. It is quite certain, owing to the difficulty of detecting the cracks, that a large number of cranks have been used in which they have existed and that no trouble has resulted."

Rubber Manufacturing Industry in Egypt

The Société des Industries Egyptiennes, Sahel El Ghelal, Boulac, Cairo, operates a factory for the manufacture of rubber goods. This factory started operations as a private concern about 11 years ago. Raw rubber and other materials are imported from England and Belgium, and a small quantity from France. Of late years the Sudan has been able to supply a small quantity of plantation rubber, there being 40 acres planted. The company sells mainly to the Egyptian Government departments, but also to private dealers; and in addition to selling wholesale, it accepts retail orders. It is claimed that the products are successfully competing with foreign manufactured rubber goods.

Technical News of the Week

Current Events in the Chemical, Metallurgical and Allied Industrial Fields
Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Flaws in Chemical Schedule Crop Out

Officials Encounter Difficulties in Applying Rates, Particularly in Case of Dyes

MEN in official circles of Washington familiar with the chemical industry express the opinion that there will be, or should be, revision of several paragraphs of the chemical schedule of the new tariff act. It is also believed that the Customs Division of the Treasury Department will have to set up rather elaborate machinery, at considerable expense, to administer properly the duties on coal-tar products, particularly dyes. Some of the rates are entirely inadequate, if the domestic industry is to be given protection sufficient to encourage its development, and there are other rates which could be lowered without harm, in the opinion of these officials after studying the new act thoroughly.

The case of synthetic organic chemicals and medicinals from other than a coal-tar base has been cited previously as one where development probably will be retarded unless higher rates are granted. The duty in the new law is 25 per cent ad valorem. Several acids and salts of large consumption are among those which it is believed should have higher protection and may receive it under the flexible tariff section when that is put into operation.

On the other hand, it is pointed out that several of the common coal-tar dyes do not require the protection of 7 cents per pound and 60 per cent ad valorem, American selling price, given by the new act, while other higher priced dyes need greater protection.

Difficulty of Comparing Dyes

In adminstering the coal-tar rates, the difficulties of determining whether an imported dye is comparable to an American product are pointed out in official circles. It has been suggested that the Customs Division will require the services of an expert chemist, with several assistants and a first-class laboratory, and this is being considered by Ernest W. Camp, chief of the division.

One of the difficulties foreseen is the case of an imported dye which may be comparable to an American product for some purposes and not for others. For instance, a case arose during existence of the dye and chemical control act where two blues, domestic and imported, produced substantially the same results excepting in one instance, the imported blue being fast to salt, whereas the domestic product was not. For ordinary dress goods the two dyes were comparable, one as good as the other, but if a manufacturer wished to use the dye in a bathing suit he would have to take the imported product. The question to be decided is if, in such instances, all the imported dye is to be assessed on the basis of American selling price, as a comparable product, if all shall be considered as non-competitive and assessed on United States value, or if part shall be assessed one way and part another, according to the use for which it is intended by the consumer under special regulations which might be drawn.

The difference in the basis of assessment, in the case of dyes heavily consumed, would run into the thousands of dollars a year. It is realized that these questions involve technical tests of many products and that customs regulations must be drawn carefully.

Other Imperfections

What is to be done to give greater protection to the coal-tar products of higher grade has not developed beyond the report that a bill for this purpose will be introduced at the next session of Congress. There are difficulties of drafting a measure which would meet the favorable consideration of Congress. If the higher products are to be given greater protection, there must be a separation of the paragraph, because admittedly some of the products do not need the rate already given. Government experts foresee many difficulties of phraseology in such a separation, with different rates for different products. However, they believe it is possible by a combination of designation by name and designation by constitution, application and price.

Another flaw in the coal-tar paragraph has been discovered by the experts in the clause providing that assessments shall be on the basis of strength in ordinary commercial use prior to July 1, 1914. Since then some strengths have been changed and others have not, so that the effect of the application of this provision gives a high concealed protection to some products and denies it to others which may need it equally as much, creating a badly balanced rate.

Rapid Development of French Water Power

Hydro-Electric Power Developed More Than Doubled Since 1913

French public sentiment is strong for the utilization of water power to overcome the dependence upon foreign imports of coal. The extent of this interest is shown by the fact that in 1913 only 930,000 hp. was generated by water, while in 1921 the total of 2,100,000 hp. of hydro-electric energy was being produced.

Important individual projects include the Rhone development, which has the navigation and irrigation phases as well as its power feature; the project for harnessing the hydro-electric forces of the River Dordogne, involving seven generating plants; the world's largest dam at Chambon, and other miscellaneous projects such as those of the Rivers Ossau and Aspe.

The use of hydro-electric power in connection with the electrochemical and electrometallurgical industries of the Isere Department is important where the production of such ferro-alloys as ferromanganese, ferrosilicon, ferro-uranium and spiegel give promise to large development. It is expected that the ferro-alloy output of France will be largely accomplished by electric furnaces within a few years.

Of a total of 2,100,000 hp. of electrical energy at present used, 650,000 hp. is for lighting, heating and minor motor force, 1,300,000 hp. for industrial use and 50,000 for traction purposes.

Power Company's Lease of Muscle Shoals Renewed

Renewal for another year of the lease under which the Alabama Power Co. operates the government's steam plant at Muscle Shoals, Ala., has been announced by Secretary Weeks.

The contract was renewed on the same terms as originally negotiated, a step which Secretary Weeks said was necessary to "enable a number of cotton mills and other industries in Southern states, including North and South Carolina, to continue operations, and which otherwise would have been compelled to close down or materially curtail production because of disturbed conditions in the coal and transportation industries and lack of developed hydro-electric power."

This renewal has no bearing on the Ford or other offers for the plant, since the contract may be canceled on 30 days' notice.

S. W. Stratton Chosen Head of M.I.T.

irector of Bureau of Standards Accepts Presidency of Institute of Technology—Hoover Regrets Inability to Hold Men With Government

DR. SAMUEL WESLEY STRATTON, for 21 years director of the ureau of Standards of the Department Commerce, has resigned to become esident of the Massachusetts Institte of Technology. The Institute has een without an executive since the eath of Dr. Richard C. MacLaurin in nuary, 1920. Dr. Ernest Fox Nichols as elected president in 1921, but was rced by ill-health to resign a few onths later without having served in fice. A committee of faculty and corration members has carried on the dministrative work.

Photo copyright by Harris & Ewing.

DR. SAMUEL WESLEY STRATTON

Government Can't Hold Best Men

In connection with Dr. Stratton's signation, Secretary Hoover issued a atement condemning the "desperately or pay allowed scientific and technical en by the government." He pointed t that the Massachusetts Institute of echnology, an educational institution, s no difficulty in paying men of r. Stratton's caliber three times the lary which the government allows em. "The inability of scientific men the government to support themlves and their families properly under e living conditions in Washington," id Secretary Hoover in his statement, nd to make provision for old age, akes it impossible for any responsible partment head to secure such men r public service at government salies."

Built Organization

As the director of the Bureau of tandards, Dr. Stratton built up an stitution. He took over the directorip of the bureau when it was created 1901. The bureau sprang from a vision in the Coast and Geodetic Surey concerned with the standardization weights and measures. During the st year of its existence the bureau as intrusted with the expenditure of appropriation of $200,000. From at small beginning Dr. Stratton was le to built up a great scientific labratory which has been intrusted with e expenditure of more than $2,000,000 a year's work. Under Dr. Stratton's rection, the bureau has grown until is the largest physical laboratory the world and employs more specialts in research than any other single ency in this or any other country.

Those who have worked for many ars with Dr. Stratton declare his rongest point is his ability to direct e work on a large number of diversid technical problems in a way so as insure maximum results. Despite e widely varying character of the perimentation conducted by the Buau of Standards, Dr. Stratton's assotes declare that he always has kept reast with the work and invariably uld be relied upon for a practical suggestion as to its conduct. He is credited with being particularly apt in recognizing when sight of the objective was being lost and when the work was being permitted to proceed along a tangent—one of the most difficult tendencies to combat in research work.

Long Record of Achievement

The high points of Dr. Stratton's career as prepared for "Who's Who in America" are as follows: Born in Litchfield, Ill., July 18, 1861. He received his B.S. degree at the University of Illinois in 1884. He was an instructor in mathematics, physics and electrical engineering at the University of Illinois from 1885 to 1892, and instructor in physics at the University of Chicago from 1892 to 1901.

Dr. Stratton has received the honorary degree of Doctor of Engineering from the University of Illinois and that of Doctor of Science from the Western University of Pennsylvania, from the University of Cambridge and from Yale. He was made a Chevalier of the Legion of Honor in 1909.

In the war with Spain he served as a Lieutenant in the navy. During the world war he was a member of the Interdepartmental Board of the Council of National Defense and of the National Advisory Committee for Aëronautics.

New York Customs Laboratory to Be Enlarged

Material enlargement of the customs division's chemical laboratory in New York has been recommended to provide facilities for the careful and painstaking chemical determination so necessary to the proper evaluation of dye and chemical imports. It is the plan of the customs division to concentrate all dye tests in New York.

Lecture by Bingham Opens Season for New Jersey Chemical Society

The attendance at the first meeting of the season of the New Jersey Chemical Society would indicate that the members have lost none of their enthusiasm during the summer recess. The meeting room was filled to the doors on Oct. 9, when Prof. Eugene C. Bingham began his address on "Fluidity and Plasticity." Dr. Bingham's talk was practically a summary of his recently published book on the same subject, and it was illustrated with a great many lantern slides.

Dr. Bingham defined his conception of fluidity using as an analogy a pack of cards lying face down on the table and slid upon one another by a horizontal force. This analogy, he said, is fundamental in the proper conception of fluidity. Mathematically, the fluidity is the reciprocal of the viscosity, but determinations of viscosity as a measure of fluidity are apt to be misleading. Instances were quoted in which a 10 per cent difference in the viscosity was observed in the same sample, using different shearing force.

The speaker continued, pointing out the relation between fluidity and plasticity, describing a series of experiments conducted with suspensions of clay in water. Up to a 12 per cent suspension the mixture was obviously a fluid, but at this concentration the fluidity was zero, and it was therefore concluded that above this point the flow of the mud took place in accordance with the laws of plastic flow. If a substance has a definite yield value it is classed as a plastic. The yield value is defined as the force necessary to start movements or flow.

Dr. Bingham described his plastometer, an instrument for determining the plasticity of a substance by forcing it through a small orifice with a definite pressure in a measured time. In the course of his experiments he found that a very small amount (0.1 per cent), of potassium carbonate lowered the yield point about 20 per cent. It was also found that as the temperature of the material was lowered the yield value reaches zero at a transition point somewhat similar to a melting point.

Fertilizer Men Ask for Data on Acid and Phosphate

Collection of statistics of sulphuric acid and acid phosphate as of Nov. 30 for the 6 months previous, with comparative data for 1921, has been suggested to the Department of Commerce by the National Fertilizer Association.

The suggestion carries with it the idea that hereafter such statistics be compiled on May 1 or June 1 and on Nov. 30, giving the trade a semi-annual census. A census for the 6 months previous was compiled last June. Change in data has been suggested so that manufacturers on Nov. 30 may have the benefit of the information in preparing for the spring business.

Reminiscences of a Consulting Chemist

Informal Talk by William Hoskins Before New York Section of Société de Chimie Industrielle

Characterized by a delightful informality and a wealth of personal reminiscences was William Hoskins' talk before the New York Section of the Société de Chimie Industrielle in Rumford Hall on Oct. 13. In introducing the speaker, Dr. Ellwood Hendrick remarked on the policy of the New York Section of this society in characterizing its meetings by a certain human interest which is lacking in the majority of technical society meetings in this country. And certainly this meeting was as full of human interest as one could ask, for Dr. Hoskins gave an intimate sketch of his own career as a consulting chemist, including numerous amusing experiences as a laboratory consultant and his early struggle to gain a livelihood in the profession.

"Analyzing a Race Track"

One of the most amusing incidents told by Dr. Hoskins was that of a client who came to him with the problem of "analyzing a race track." It developed that this client, an engineer, had been commissioned with the project of constructing a race track in Chicago, and he was frank to admit that he knew nothing about the subject. He had heard, however, that the race track at Louisville, Ky., was one of the best in the country and consequently he determined to build the Chicago track as much like it as possible. Dr. Hoskins became interested in the problem and obtained a number of samples of the clay, sand and loam from the Louisville track and by a combination of analytical chemistry, common sense and good luck the race track was finally built and proved to be fully as good as its renowned model. Another of the interesting problems which Dr. Hoskins has encountered was that of studying the smoke problem in Chicago and its relation to the possible electrification of the local railways. In this investigation he and an assistant spent several months in an automobile, sampling air in various sections of the city and finally turned out a very comprehensive report on the subject which was accepted as a piece of pioneer work of its kind.

Dr. Hoskins is extremely modest and was inclined to belittle the work he has done and the friends he has made by his generous advice and help. One could not fail to gather an impression of some of the characteristics of the man which have contributed to his success. For instance, he told of how he built a $5,000 house on a $500 equity, at a weekly salary of $15. He paid for the house by the work he did in his spare time in the basement on the oxy-hydrogen blowpipe.

A client once came to him with a sample of ore. Dr. Hoskins surprised him by asking him from what part of Alaska it came. Pressed for an explanation, he explained that the large number of samples of ores that were brought to him in the course of a year had given him enough experience to be able to tell fairly definitely from what part of the world any particular ore was brought. As a matter of fact, he added confidentially, it was quite simple. The sample was wrapped in a Sitka newspaper.

Experiments With Nickel-Chromium Alloy and Thermit

Dr. Hoskins traced the events in his career which led to the development of the nickel-chromium alloy which he has commercialized for use in pyrometers. When he was 14 years old he saw in a popular magazine a procedure for making synthetic diamonds. He followed the directions and carried on the experiment for 2 years, but, of course, was unsuccessful as far as producing diamonds went. This, however, gave him an interest in synthetic precious stones. Some time later, when he was interested in the oxy-hydrogen blowpipe, he attempted to continue work on this hobby by fusing ruby chips into large rubies. The main difficulty in the way of this ambitious scheme was the lack of funds to purchase small rubies, and he finally gave up the idea of them until Goldschmidt perfected the Thermit process This discovery stimulated his imagination again, and he determined to attempt to make synthetic rubies from ferric oxide and granular alumina. He, therefore, laboriously made up 200 lb. of Thermit and a graphite crucible in which he mxied the ingredients. He conducted the experiment in a blacksmith shop over which lived a colored family. Having made all the preparations he ignited the 200 lb. of Thermit. The colored family upstairs moved out and the fire department appeared on the scene. Needless to say, no rubies resulted from the experiment. This experience with Thermit, however, was recalled to mind when he began working on a nickel-chromium alloy for a thermopile. He successfully applied Thermit to the manufacture of various alloys, but after developing the thermopile it turned out that the practical application of it was very remote, but far from being discouraged with this failure the enthusiastic experimenter applied the very properties of the alloy which made it objectionable for its intended use to other uses. The problem of drawing the new alloy into wire was a long and tedious one, and the inventor encountered many obstacles which, amusing as they seem today, must have been extremely discouraging.

Chapter Officers Elected

Officers of the chapter for the coming year were elected as follows: President, Ellwood Hendrick; vice-president, Raymond F. Bacon; secretary, Arthur W. Thomas; treasurer, T. V. N. Dorr; council, Jerome Alexander, Leo H. Baekeland, M. T. Bogert, George F. Kuns, Charles F. Chandler, Charles H. Herty, D. D. Jackson, Ralph H. McKee, William H. Nichols, Paul Wack, H. C. Parmelee, A. H. Peter, J. E. Zanetti.

C. R. Richards Inaugurated President of Lehigh

Proposes to Extend Engineering Research Activities Without Neglecting Instruction

Before an audience of delegates fro other colleges, alumni and undergra uates of Lehigh and friends of t university which crowded the spacio Packer Memorial Chapel, Dr. Charl Russ Richards, former dean of the co lege of engineering of the Universi of Illinois, was inaugurated preside of Lehigh University on Oct. 15.

In the course of his speech Dr. Ric ards expressed his idea of the relati between industry and science as fo lows:

> Since the development of technological science and of technical education has followed rather than preceded the development of the basic industries, it was necessary to build these industries by emperical methods and procedures. Naturally such methods were expensive and wasteful. Only during recent years have we come to understand that there is a limit to our resources and that they must be conserved by every method which modern science can devise.
>
> Undoubtedly the solution of many of the problems of the industries can best and most economically be undertaken through co-operation with the universities and technical schools, in so far at least as these problems involve the discovery of scientific information of basic importance. Educational institutions are interested in the establishment of facts, and work conducted by them is therefore less likely to be affected by prejudices. Furthermore many of these institutions have facilities in apparatus and men which cannot readily be duplicated by any private laboratory. Thus those engaged in engineering research in a modern university have advantages which accrue to them through association with professors of physics, chemistry, bacteriology and other branches of pure science which may have a direct bearing upon engineering investigations in progress.

President Richards struck the no which told his audience that Lehigh, f 60 years a teaching college, was embark in the great work of enginee ing research when he stated that "whi teaching is the obvious and apparent the chief function of a university, should be its purpose to place scientif research in a position of equal impo tance with the work of instruction, f the world must largely depend upon to extend the boundaries of knowled and to show its applications to t affairs of life."

Steel Works Offers Jobs to Carnegie Students

To assist students working their wa through Carnegie Institute of Tec nology, the Jones & Laughlin Ste Co., of Pittsburgh, has arranged to en ploy students in the steel mills on Fr day and Saturday nights or all da Saturday. The shifts are of 10 hou length. Jones & Laughlin is the fir large concern in Pittsburgh to come t the aid of students in need of fina cial aid. The arrangement is pleasin to the administration at Carnegie Tec because of the opportunity it gives t the students in the College of Enginee ing to acquire practical as well a theoretical knowledge.

No Immediate Shortage of Industrial Coal

As a part of its campaign to stabilize the fuel situation through co-operative effort between the government and business, the Chamber of Commerce of the United States has made a survey of coal supplies in the states east of the Mississippi and north of the Ohio River. This part of the country has been regarded as the critical territory in the event of a coal shortage this winter.

The information gathered by the chamber which was obtained through local Chambers of Commerce, has been summarized as follows:

There are practically no supplies in the hands of local dealers.
Public utilities, about 45 days.
Byproduct coke plants fairly well supplied.
Steel works fairly well supplied.
General industries about 45 days.
The bituminous situation is becoming easier.
There seems to be no general complaint as to price.
The critical situation is that of obtaining a sufficient domestic supply in advance of cold weather, especially for the Great Lakes states, and the populous areas of New York State, New England and the Central Atlantic states.
There is much interest being taken in the use of oil.
There is a general increase in the use of coke for domestic fuel.
Certain cities have very effective systems of gathering information and distributing their coal, while others have nothing.

One of the first steps taken by the chamber in its campaign was to call on industries throughout the country to co-operate by confining purchases of coal to current needs as far as possible.

Petroleum Institute and A.C.S. Co-operate on Fuel Problems

First efforts to insure future supplies of motor fuels and oils have been started by the American Petroleum Institute, in co-operation with the special committee of the American Chemical Society which has undertaken the task. A list of problems was submitted at the recent meeting of the society in Pittsburgh, before the Petroleum Section by W. F. Farragher of Mellon Institute, and several of the most important, from a standpoint of immediate needs, have been chosen for immediate attack, as follows:

1. Thorough scientific investigation of fractionating columns. The study will be directed toward greater yields, purity, efficiency of operation, etc.
2. Preparation of rational specifications for petroleum products, such specifications to be based on actual research work. More rational volatility specifications for gasoline, and tests for "oiliness" of lubricants.
3. Investigations as to the actual need of highly refining gasoline for motor fuel; is it necessary to remove bad smelling sulphur compounds completely in order to obtain efficient service from the gasoline? Will these compounds injure the engine?
4. A study of the fundamental causes of carbon formation in cylinders; study effect of addition agents.
5. A thorough study of lubrication from a colloid chemical standpoint.
6. The chemistry of petroleum hydrocarbons, particularly of the higher homologs.
7. The chemistry of the sulphur, nitrogen and oxygen compounds in petroleum.
8. The chemistry of sulphuric acid refining of oils.
9. The causes and mechanism of color changes in oils.

British Prepared for Gas

Significance is attached in Washington to the fact that the British army being landed to protect the Dardanelles is equipped with gas masks. Despite the fact that it is highly improbable that the Turks have any supplies of gas or facilities for using it, each British soldier carries his gas mask ready for instant use in exactly the same way that he did on the western front during the World War.

The work is to be directed by the American Petroleum Institute, the Petroleum Section of the American Chemical Society helping in an advisory capacity only.

The Petroleum Section's committee on petroleum research was appointed to co-operate with Van H. Manning, director of research for the American Petroleum Institute. The following are members: R. R. Matthews, Roxana Petroleum Corporation; R. E. Wilson, Massachusetts Institute of Technology; C. E. Waters, Bureau of Standards; N. A. C. Smith, Bureau of Mines; R. P. Anderson, United Natural Gas Co.; E. W. Dean, Standard Oil Co. of New Jersey; and W. F. Farragher, Mellon Institute of Industrial Research, chairman.

Several Novelties at Ordnance Tests

Demonstrations to Engineers and Technical Men Regarded as Success

Engineers and technical men in the army service regard the demonstration of ordnance material at the Aberdeen Proving Ground on Oct. 6 as the most successful exhibit of this type yet conducted. The principal benefit from the army point of view is to bring home to men of technical experience, who can appreciate the exacting requirements of military prepardness, the destructive agents which may be brought against us. By actually visualizing the engines of war, it is possible to obtain a more precise conception, army officers believe, of the engineering and technical requirements for their production.

While the manipulation of the big guns always constitutes the most interesting portion of the programs at the Proving Grounds, it is believed that the greatest interest centered around the semi-automatic shoulder rifle, which made its first public appearance at the Aberdeen demonstration. The weapon was developed at the Springfield Armory, under the Garand patents. It is believed to be the most notable step forward in rifle production in recent years.

Much interest also centered on a new 14-in. gun on a railway mount. This weapon was displayed publicly for the first time at the meet. It is regarded as a notable achievement to mount on a railroad car a gun 50 ft. in length, capable of hurling a 1,500-lb. projectile a distance of 23 miles.

Another of the Ordnance Department's recent achievements which was on display was a new supersensitive fused shell which will burst on the slightest contact, even if nothing more substantial than the cloth of an airplane wing is pierced.

Radio was successfully employed in directing tank operations. A tractor for reconnaisance purposes was demonstrated publicly for the first time. Special provision is made to facilitate observation on the part of the two officers which the tractor is designed to carry. It has a speed of 12 miles across country and is equipped so as to float when it is necessary to cross streams.

Salesmen Enthusiastic Over Chemical Courses

The tower banquet hall of the College of the City of New York was the scene of the opening fall meeting of the New York Chapter of the Salesmen's Association of the American Chemical Industry on Oct. 13. The annual election of officers of the New York Chapter resulted in the appointment of John A. Chew, sales manager of the Warner Chemical Co., as president, George Ashworth, of the Dow Chemical Co., as treasurer, and D. H. Killeffer, of the *Journal of Industrial and Engineering Chemistry*, as secretary.

The excellent dinner which was arranged through the co-operation of Drs. Breithut, Robinson and Moody, was thoroughly enjoyed as was attested by the fact that the members lingered around the table until 9 o'clock. The meeting then adjourned to the Doremus chemical lecture room, where Dr. F. E. Breithut presented a series of experiments with liquid air which were exceedingly interesting. Dr. Breithut then outlined a proposed series of lectures on "The Chemistry of Common Things," which he plans to organize for the association. He outlined the scope of the course and the facilities for co-operative work. It is planned to make the lectures of a very practical nature and to present information that will be of great value to salesmen in the chemical industry. The first lecture will describe how a chemist works. This will be followed by a series of talks on the chemistry of gases, liquids, solids, solutions, acids and alkalis, metals and their source, carbon and its compounds. The ninth lecture, on "The Language of Chemistry," will go into the nomenclature which is sometimes so puzzling to the layman. The final lecture will be on "Economic Chemistry," a subject which Dr. Breithut is especially well qualified to discuss.

The association membership received the proposal with great enthusiasm. From the fifty members who were present at the meeting, thirty-three subscriptions to the course were obtained, and it is practically assured that the necessary quota of fifty members will be made up in a short time and the course started.

To Educate Legislators on Importance of Chemical Industry

So that new members entering the Senate or the House of Representatives may be given an idea, in concise form, of the value of chemistry to the nation, the American Chemical Society is bringing out a syllabus which it will place in their hands. It also is to be circulated in a limited way to others with the idea of emphasizing the essential nature of an American chemical industry. The concise character of the production may be gained from the reference made to the importance of chemistry to the national defense. It follows:

"Chemistry is essential to the production of every type of material required for national defense. War involves the entire national resources of a country, and the nation best fitted to make full use of its resources is most likely to be the victor. Without far-reaching work by chemists, such ability to defend a country is negligible. The German general Ludendorff in an interview published in American newspapers Sunday, Oct. 8, 1922, declared that in the next great war airships, chemicals and a few regiments of highly trained men will be supreme. Chemistry produces explosives, materials for aviation from dope for airplane wings to helium for dirigibles, materials for camouflage, toxic gases and equipment for protection against gases. Many non-poisonous smoke-screens, tear gas and other materials for 'humane warfare' are due to chemistry. It is the controlling factor in ordnance, in medicine and in sanitation. Its importance in national defense can not be overestimated."

Synthetic Organic Manufacturers Consider Tariff Effects

A meeting of the Synthetic Organic Chemical Manufacturers Association was held on Oct. 13 at the Hotel Pennsylvania, New York, with sixty representatives of chemical manufacturers present. The morning session was devoted to a meeting of the general association and the afternoon to meetings of the Dyestuffs Section, Crudes and Intermediates Section and the Medicinal and Fine Organic Chemicals Section.

At the conclusion of the luncheon held after the adjournment of the general session, the manufacturers were addressed by Dr. John H. Finley of the editorial staff of the New York *Times*. Dr. Finley emphasized the importance of the industry represented at the meeting and the multiplicity of the products so essential to the other industries of the country, and commented especially on the work of the chemists and the chemical manufacturers in transforming crude material of but little value to such highly important compounds as dyes, medicinals, etc. He felt that the present stress of the industry was due to lack of public understanding and pointed out how important a role the press of the country could play in bringing about a full conception by the people of the entire country that in this industry lay a national asset which should be safeguarded in every possible way. Regardless of the general views of tariff protection, he unhesitatingly joined with the views which he quoted of the late Lord Moulton, the eminent free-trader of England, that such an industry is exceptional in its character and in its preservation all citizens should unite.

At the general session of the association the subject of prime interest was the probable effect upon the industry of the present tariff act. There was a unanimity of feeling that many important products were markedly unprotected and all felt the injustice of the situation which took from the President power to increase rates where it could be clearly shown that protection was inadequate. As to direct effects up to date of the bill, it developed that as yet but little of the material manufactured by this industry had been admitted into this country, as the Customs Division had not yet drafted its regulations for administering the many complicated features in the new bill. The manufacturers, therefore, would have to wait before they could determine very accurately how disastrous foreign competition would prove.

Personal

Dr. JOSHUA BERNHARDT, of Rochester, N. Y., has been appointed head of the Tariff Commission's Sugar Division. Dr. Bernhardt served during the war as a sugar specialist for the Food Administration and for the Sugar Equalization Board. He is the author of a two-volume work on "Government Control of the Sugar Industry and Trade" and of another two-volume treatise under the title of "A Statistical Survey of the Sugar Industry and Trade." For the past 18 months Dr. Bernhardt has been a member of the staff of the Institute of Government Research and has written monographs covering the work of the Tariff Commission, the Alaskan Engineering Commission, the Interstate Commerce Commission, the Railroad Labor Board and the Federal Reserve Board. He was educated at the University of Rochester and at Johns Hopkins University.

C. R. DELONG, who recently left the United States Tariff Commission to take charge of the Chemical Commodity Division for the Department of Commerce, has been selected to return to the Tariff Commission as head of its Chemical Division.

Dr. MARION DORSET, chief of the Biochemical Division of the Bureau of Animal Industry, Department of Agriculture, has been designated to cooperate in an unofficial and consultative capacity with the Anthrax Advisory Committee. Dr. Dorset has been connected with the Department of Agriculture since 1894, and has held his present office since 1904.

CHARLES R. DOWNS and JOHN M WEISS, of New York, were awarde the Howard N. Potts medal by the com mittee on science and the arts of th Franklin Institute. The award wa made "in consideration of their notabl achievement in the scientific and com mercial development of the catalyti vapor-phase oxidation of benzene t maleic acid and their pioneer work i developing a commercial process fo changing aromatic to aliphatic com pounds."

Dr. A. R. FORTSCH, of the Iowa State University, will become research chemist in the laboratory of the Standard Oil Co. at Whiting, Indiana.

W. S. LANDIS, chief technologist for the American Cyanamid Co., was given the degree of D.Sc. on Oct. 15 by Lehigh University. HARLAN S. MINER, chief chemist for the Welsbach Co., received the same honor. Both gentlemen are alumni of Lehigh.

C. C. LATUS gave an interesting address before the members of the Pittsburgh Paint, Oil and Varnish Club, Pittsburgh, Pa., on Oct. 5, on the subject, "An Economic View of Central Europe."

ERNEST T. TRIGG has been elected president of John Lucas & Co., Philadelphia, Pa., manufacturers of paints and varnishes, succeeding J. W. LUCAS, who has become chairman of the board of directors. JAMES F. LUCAS was elected vice-president to succeed Mr. Trigg.

Obituary

WILLIAM C. ALLEN, general manager of the Tarrant Co., manufacturer of chemicals, died at his home in Brooklyn, N. Y., Sept. 24, as the result of injuries received when struck by an automobile. He was born in 1844, and had been associated with the Tarrant Co. for the past 50 years.

T. K. MCKNIGHT, who represented Crane Co. in Cleveland and formerly held a similar position in the Detroit and Pittsburgh districts, died suddenly in Cleveland on Sept. 16.

FRANK SHERMAN WASHBURN, chairman of the board of directors of the American Cyanamid Co., a leader in American engineering, died at his home in Rye, N. Y., at 2:30 a.m. Monday, Oct. 9. Death was due to bronchial pneumonia. Mr. Washburn is survived by his wife, a son, a daughter and two sisters, Mrs. C. J. Swan and Mrs. G. R. Dean, both of Chicago.

DR. J. FLEMING WHITE, consulting chemist for the General Chemical Co. for the past 37 years, died at his residence in Buffalo, N. Y., on Sept. 25, aged 73 years. Prior to becoming connected with the General Chemical organization he was connected with Harvard University and engaged in research work for the government.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

How About Our Foreign Trade?

An Attempt to Answer This Question by a Study of the General Trend of Imports and Exports of Basic Commodities and of Chemical and Allied Products

WHAT influence will the new high-protective tariff have on our foreign trade? Can we continue to export if imports are shut off? What will become of our favorable balance of trade? Questions of this sort will not down even though their answers for the most part must wait for the tedious process of international readjustment. Certain it is, of course, that the great groups of commodities for which the world must depend on the United States will continue in demand, although the extent of this demand must be measured by the foreigner's ability to pay. Likewise this country will continue to import necessities and other materials not produced here. Certain commodities for which the preference is for the foreign product will also be imported in spite of higher duties. Here, however, the quantity will depend on our willingness rather than ability to pay the price. The first 6 months of the current year showed a very encouraging trend in our foreign trade. After our exports had reached a low point in February, 1922, there was a distinct upward movement as exports rose from the low of 251 million dollars to 335 millions in June. The lowest point reached in imports since the decline which began in 1920 was in July, 1921. Month by month since that time the value of our imports has increased from 178 million dollars in July, 1921, to 260 millions in June and to 281 millions in August, 1922. The latter month to a large extent reflects the flood of imported merchandise received in anticipation of the enactment of the new high tariff. The monthly totals for August, which have just been issued by the Bureau of Foreign and Domestic Commerce, are shown in Table I.

Our balance of trade—i.e., the excess of exports over imports, has been gradually dwindling. In the fiscal year 1921-22 it amounted to 1,163 million dollars, as compared with 1,976 millions in the calendar year 1921 and 2,862 millions in the fiscal year 1920-21. The Research Division of the Bureau points out that although the trade balance in 1921-22 was slightly more than one-fourth as large as that for the fiscal year 1918-19 and less than half that of 1917-18 and 1919-20, it was nevertheless two and one-half times as large as the balance for 1913-14—a typical pre-war year. In 1913-14 the excess of exports over imports was 11 per cent of the total trade; last year it was 18 per cent.

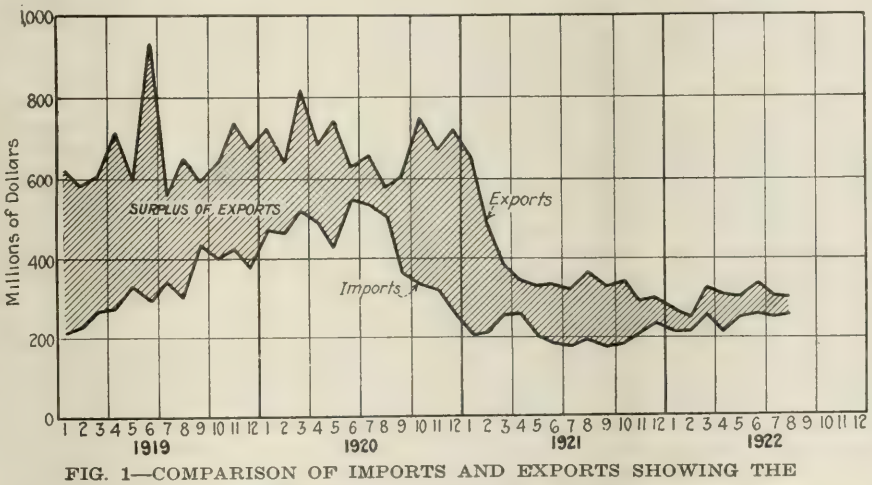

FIG. 1—COMPARISON OF IMPORTS AND EXPORTS SHOWING THE DIMINISHING BALANCE OF TRADE

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	153.77
Last week	150.78
October, 1921	151
October, 1920	263
April, 1918 (high)	286
April, 1921 (low)	140

Of the twenty-five commodities included in this index four advanced in price, there was one decline and the prices of the remainder did not change. Methanol, glycerine, formaldehyde and aniline oil caused an increase in the index number which more than offset the slight decrease caused by caustic potash.

The spread between imports and exports is shown graphically in Fig. 1. Its dwindling tendency is particularly significant in view of the commonly held theory that as a creditor nation our favorable trade balance must ultimately change to an unfavorable one. The new Chemical Division of the Department of Commerce has recently announced that since our export trade in chemicals and allied products is increasing so rapidly, it is quite probable that the total for 1922 will exceed that for 1921. This statement is supported by the fact that our exports for the first 7 months of 1922 showed a decrease of 3 per cent over

TABLE I—ANALYSIS OF FOREIGN COMMERCE FOR THE MONTH OF AUGUST, 1922

Groups	Month of August 1922	Month of August 1921	8 Months Ended August 1922	8 Months Ended August 1921
Imports				
Crude materials for use in manufacturing	$110,285,850	$71,525,960	$696,969,883	$563,733,290
Foodstuffs, crude, and food animals	22,489,316	18,921,616	211,856,654	202,007,847
Foodstuffs, partly or wholly manufactured	42,404,794	27,096,025	275,212,363	274,869,332
Manufactures for further use in manufact'g	48,430,514	25,160,325	328,283,585	227,588,260
Manufactures ready for consumption	55,858,174	49,889,223	430,881,213	408,745,339
Miscellaneous	1,944,262	2,175,602	9,752,898	11,460,167
Total imports	$281,412,910	$194,768,751	$1,952,956,596	$1,693,404,235
Exports				
Crude materials for use in manufacturing	$47,872,888	$65,278,951	$519,644,391	$615,798,544
Foodstuffs, crude, and food animals	61,339,609	105,877,509	292,791,310	525,643,525
Foodstuffs, partly or wholly manufactured	46,071,986	66,607,308	404,066,204	479,278,830
Manufactures for further use in manufact'g	35,708,965	25,050,067	309,005,058	275,884,025
Manufactures ready for consumption	104,871,560	97,318,160	847,925,438	1,241,888,759
Miscellaneous	407,071	493,641	4 296,754	4,666,999
Total domestic exports	$296,272,079	$360,625,636	$2,377,729,155	$3,143,160,682
Foreign merchandise exported	5,532,539	6,261,902	46,058,717	83,386,144
Total exports	$301,804,618	$366,887,538	$2,423,787,872	$3,226,546,826

the corresponding period of 1921, while the exports for the first eight months of 1922 showed only a very slight decrease—less than 1 per cent—over the same period in 1921. Going back over our exports month by month for the first 8 months of these 2 years, the rate of decrease has been gradually lessened, from 28 per cent for the first quarter to less than 1 per cent for the 8 months ended Aug. 31. Table II shows by monthly periods the gradual improvement in our export trade.

TABLE II—MONTHLY IMPROVEMENT IN CHEMICAL EXPORTS

Period	Decrease in Value of Exports in 1922 Over 1921 Per Cent
January	53
January – February	43
January – March	28
January – April	20
January – May	11
January – June	7
January – July	3
January – August	0.8

When it is taken into account that this table is based on value, it can be readily seen that with continued improvement our export trade in chemicals for 1922 will show an encouraging increase over 1921.

The total exports of chemicals and allied products for the first 8 months of 1922 were valued at $71,476,203, as compared with $72,081,335 in the corresponding period of 1921. Marked increases again occurred in our exports of fertilizers and fertilizer materials, and in naval stores, gums and resins.

Commodity Totals

Caustic soda and borax continued to show the largest increases of all chemicals, 360 per cent and 300 per cent respectively, 107,934,500 lb. and 10,361,250 lb., having been exported during this period. Other chemicals showing important increases were sodium silicate, bleaching powder, glycerine, acetate of lime, sodium bicarbonate, ammonium sulphate and copper sulphate. Of the 4,218,288 lb. of ammonia and ammonium compounds (excluding ammonia sulphate) exported, it is interesting to note that over one-quarter of the amount was exported in the month of August.

The shipments of fertilizers and fertilizer materials were 652,359 tons, valued at $12,032,707, in 1922, as compared with 561,666 tons, valued at $10,363,628, in 1921, an increase of nearly 20 per cent in quantity. Of a total of 111,676 tons of ammonia sulphate exported, over one-half was again shipped to Japan and one-quarter was sent to Spain.

Large increases are again noticed in the exports of naval stores, the combined exports of tar, pitch and wood turpentine increasing 260 per cent, while spirits of turpentine increased 67 per cent and rosin 58 per cent. The United Kingdom still continues to be our best customer for rosin and spirits of turpentine, taking nearly one-third and one-half respectively by value. The total exports of naval stores were $11,348,000 in 1922, as compared with $6,843,000 in 1921.

The exports of explosives more than doubled in this period, from 5,692,000 lb. ($1,361,000) in 1921, to 11,657,000 lb. ($2,121,300) in 1922. The amount of dynamite exported increased from 5,032,860 lb. in 1921, to 8,235,000 lb. in 1922.

Perfumeries, cosmetics and all toilet preparations increased over one-quarter from a total valuation of $3,000,000 in 1921 to nearly $4,000,000 in 1922.

Although the figures for the exports of "Pigments, paints and varnishes" still continue to indicate a decrease in exports from $9,009,000 in 1921 to $7,329,000 in 1922, there were marked increases in the exports of red lead and litharge and in zinc oxide, from less than 1,000,000 lb. and 3,000,000 lb., respectively, in 1921, to nearly 2,500,000 lb. and 5,000,000 lb. in 1922. Decreases are still evident in the exports of ready-mixed paints, white lead, and other paints.

Other noticeable decreases were in the exports of benzol, from $2,582,600 in 1921 to 1,994,000 in 1922, and coal-tar colors, dyes and stains other than color lakes, from $3,767,400 to $2,431,400.

The New York Market

New York, Oct. 16, 1922.

Inquiries by consumers have shown considerable diminution during the past week, due to the price advances which have occurred since the new tariff went into effect. Interest, however, has been keen among leading dealers, as the present market has reached the highest level since the beginning of 1921. The only disturbing influence was the announcement of a reduction in price by producers of oxalic acid. The new price was primarily made to meet the competition of foreign makers. Alkalis for home consumption showed an abundance of activity. Producers of formaldehyde again advanced prices, increased cost of manufacture being given as the reason. The acute shortage in commercial white arsenic is keeping the market in a very tight position on spot and immediate future shipments. There has been a slight decrease in quotations of caustic potash and barium chloride. Weak holders of these items have offered some round lots during the week at lower figures, but consumers have shown little desire to increase their stocks. Acetate of soda remains scarce and strong on spot. Prussiate of potash and soda are holding their late advances and several fair-sized lots have been sold. The market, in general, appears on the road to stable prosperity and some of the leaders are looking forward to the last quarter of 1922 with unusual optimism.

General and Special Chemicals

Arsenic—Spot material has been selling around 10c. per lb. This figure is the highest recorded since the early part of 1921. The consuming trade, largely producers of insecticides, are very active. Forward shipments are bringing 9½@9¾c. per lb.

Barium Chloride—Quotations among some dealers were slightly lower, with figures ranging around $100@$102 per ton. Leading producers are quoting $105. The demand has not, however, been active during the past week.

Caustic Potash—The 88-92 per cent imported material has been sold at 6¼c. per lb., but the majority of strong holders are asking 6½c. There was a fair inquiry in the market, although actual sales were not as extensive as recorded a week ago.

Caustic Soda—Export business has been quite dull of late and prices have reduced to $3.45@$3.50 per 100 lb. for standard brand goods. The only real activity is in the domestic consumption, where prices are holding at 3¾c. per lb. Contract price quotations remain unchanged.

Chlorate of Potash—Imported material is quoted at 7½@7¾c. per lb. The market has been quite firm at these figures and demand continued active. Domestic factors quote 8½c. per lb.

Chlorate of Soda—Domestic producers are firm at 6½c. per lb., f.o.b. works and report a moderate amount of new business at this level. Imported goods is strongly maintained at 6½c. per lb. on spot.

Formaldehyde — Manufacturers announced an advance to 11½c. per lb. on round lots and 12c. for smaller quantities. Increased price of methanol is chiefly the cause of the late advance. Demand is active.

Oxalic Acid—Sales of imported material are reported at 13¾c. per lb. for arrival, duty paid. American manufacturers have reduced prices to 14c. per lb., in an effort to meet foreign competition. Spot domestic goods are quoted at 16c. per lb., but the market is somewhat irregular.

Prussiate of Potash — Leading importers reported sales at 38½c. per lb. on spot for yellow material. Shipments are offered at 37½@38c. per lb., duty paid. The red variety is offered at about 95c. per lb.

Soda Ash—The spot market is firmly held at $1.75 per 100 lb., single bags, and $1.95 in barrels, carload lots. Contract business was reported quite active among producers at $1.20 per 100 lb., basis 48 per cent, f.o.b. works.

Coal-Tar Products

The market on crude coal-tar material presented a very strong appearance and acute advances were reported in several items. Phenol has been the feature of this market and spot goods were exceedingly scarce. Cresol, U.S.P., has been advanced 2c. per lb. by producers. Cresylic acid has also recorded gains ranging from 3@4c. per gal. The consuming trades have shown considerable activity of late and the increased prices are primarily on account of this demand. Aniline oil producers are quite firm at the recently advanced figures.

Naphthalene has remained quiet and several weak holders are shading prices in an effort to move stocks. Benzene and toluene are very strong and can only be quoted for future shipments.

Cresol — U.S.P. material has advanced to 14c. per lb. in bulk and to 20c. on smaller quantities.

Phenol — The spot market is very tight. Several sales have been made at 26c. per lb. for prime white U.S.P. crystals. Manufacturers are sold up well into the future and the general condition is very strong.

The Chicago Market

CHICAGO, OCT. 12, 1922.

The chemical market was in a much healthier condition the past 2 weeks and it appeared that this condition would be more or less permanent. Labor troubles have about ceased and transportation difficulties are gradually being adjusted, with the result that business in general is better than for some time past. Prices, as a rule, were very firm, with advances numerous. However, these advances were mainly on imported materials that were affected by the new tariff. Supplies were not heavy in any direction, but with one or two exceptions no serious shortages were in evidence.

General Chemicals

Caustic soda maintained its firm position and was reported to be moving in a good volume. The solid 76 per cent material was offered at $3.50@$3.75 per 100 lb., priced according to quantity and holder, while the ground of the same test was quoted at $4.25@$4.50. *Caustic potash* was available in one direction at 7¼c. for the 88-92 per cent material, but most factors held their prices firm at 7½c. *Soda ash* was in good demand and was quoted in cooperage at $2.25 per 100 lb. delivered to the buyer's plant. *Sal soda* moved in a routine way at $1.90 per 100 lb.

Potash alum was very firm, with 5½c. per lb. the inside price on the iron-free lumps. The powdered material of the same grade was scarce at 6½c. per lb. in large casks. *Sal ammoniac* continued firm, with 7¾c. per lb. the best price noted for the 98-100 per cent white granular. All barium salts were in a firm position, with only moderate supplies available. *Barium chloride* was quoted in small lots by one factor at $110 per ton but it was doubtful if a large order could have been taken care of. The carbonate was quoted for spot delivery at $90 per ton, but, like the chloride, only limited supplies were available. Bleach was firm, with $2.60 per 100 lb. the prevailing price for small or moderate lots. *Copper sulphate* was available in fair quantities at 6@6½c. per lb. *Carbon tetrachloride* was unchanged and apparently enjoyed good demand. The large drums were quoted at 9c. per lb. delivered to the buyer's store. *Carbon bisulphide* was scarce on spot and supplies were firmly held at 7½c. per lb. *Formaldehyde* was again sharply advanced, the new level being 12½c. for barrels in less than carload lots. *Furfural* was reduced to 25c. per lb. in ton lots. Glycerine was steady at 18½c. per lb. for the c.p. material in drums. *Magnesium* metal was quiet at $1.35 per lb. for the powder. *Phosphoric anhydride* was in poor demand and was offered in 1-lb. tins at 42c. per lb.

Bichromates were steady and moved in a fair volume. *Potassium bichromate* was quoted in single barrels at 12@13c. per lb. and the *soda* at 9@9½c. *Potassium permanganate* was easier and spot supplies of the U.S.P. crystals were available at 18c. per lb. *Red prussiate of potash* was offered in very small quantities by one holder at 92c. per lb. The *yellow prussiate of potash* was scarce at 38c. per lb.

Linseed Oil and Turpentine

Turpentine was considered high priced by most consumers and only small quantities for immediate consumption were sold. Today's price for single drums was $1.45 per gal.

Linseed oil moved in a better way, but very few consumers were taking on supplies beyond their immediate needs. The boiled oil was quoted today at 96c. per gal. in single drums and the raw at 94c.

The Iron and Steel Market

PITTSBURGH, Oct. 13, 1922.

Fundamental conditions in the steel market have turned distinctly soft, but in the actual current market there is little softness apparent, there being support, both real and sentimental, by the existing transportation difficulties, which prevent full shipments being made from mill in all cases and which also block delivery, more or less, to various consumers.

There are car shortages at the majority of steel plants, and there are probably few at which there is not some accumulation of finished steel. No large tonnage has piled up. Whether correctly or not, it was estimated in some quarters on July 1, 1920, that 3,000,000 tons of finished steel lay at mill, awaiting cars. An estimate now would not be a tenth of that amount.

Effects of Car Shortage

While the steel mills probably could make little if any more steel than they are making, there is no desire to make more, since it is impossible to ship all the steel that is being made. When the market has the physical and moral support of shipments restricted by transportation conditions and does not appear particularly strong at that, it is evident that it is on the verge of the general readjustment that was expected to follow at a longer or shorter interval the ending of the coal strike. In April and May it was a very common view that the coal strike, by its sentimental influence, was making the steel market stronger and more active than it would be otherwise.

Delivery premiums continue on some steel products, but are tending to narrow, and probably will shortly disappear entirely. Basis prices naturally could not be expected to yield when there is a premium market in some branches of the trade, but they may yield later, and unless circumstances that cannot now be foreseen should arise it is entirely probable that basis prices will eventually decline, before there is another general buying movement in steel. The experience of two years ago will be repeated on a smaller scale. Steel prices have very much less room for decline, but the character of the market will not be essentially different.

Bars, shapes and plates are quotable generally at 2@2.25c. Black sheets in the open market are at 3.50@3.60c. The Steel Corporation's price is 3.35c., but it is out of the market. One or two mills are asking 3.75c., but do not seem to be selling much tonnage. Nails are steady at $2.70.

The Steel Corporation's unfilled obligations increased by 741,502 tons in September, against increases of 173,944 tons in August and 140,630 tons in July. The September showing is not illuminating because it is not known how much of the large rail tonnage put under cover in the month got into actual form for entering before the close of the month. Some of the business remained to appear in the October statement. With rails eliminated the September showing would probably not be much different from those of the two preceding months.

Coke and Iron Prices

Connellsville coke and merchant pig iron have just begun an extensive price readjustment. Coke was strong for several weeks, at around $12, and furnaces desiring to buy in order to resume operations had to buy from several different plants to make up the tonnage. In the past few days prices have suddenly begun to weaken, and with its usual sensitiveness the market will probably decline sharply. A week ago the market was strong at $12, while now coke is offered at $11 with few takers. Coke has sometimes sold at less than the market price of the coal involved, plus cost of coking. The computation at present would be 1½ times $3.50 plus $1.25, or $6.50. By precedent, coke could sell for less than $6.50 or it could sell at double that figure, according to whether the balance between offerings and demand were disturbed a trifle one way or the other.

Cherry Valley furnace and McKeefrey furnace, both at Leetonia, Ohio, are about to get into blast. While merchant furnace resumptions have been only occasional, there has really been a fair measure of resumptions, and with pig iron scarcely salable in the past few weeks at prices asked, a substantial decline in the market is to be expected. The market now is quotable, roughly, at $31 for basic, $33.50 for bessemer and $32.50 for foundry, f.o.b. valleys or Johnstown, freight to Pittsburgh being $1.77 in each case. There are no definite bids, representing prices at which consumers would buy freely.

Sodium potassium tartrate (Rochelle salts)	lb.	- -	.18 – .21
Sodium prussiate, yellow	lb.	.24 – .24½	.24½ – .25
Sodium silicate, (40 deg. in drums)	100 lb.	.80 – 1.00	1.05 – 1.25
Sodium silicate, (60 deg. in drums)	100 lb.	2.25 – 2.40	2.45 – 2.75
Sodium sulphate, crystals (glaubers salt)	100 lbs.	.85 – .95	1.00 – 1.40
Sodium sulphide, fused, 60-62 per cent (conc.)	lb.	.04 – .04½	.04¾ – .05
Sodium sulphite, crystals	lb.	.03¾ – .03¾	.03¾ – .04¼
Strontium nitrate, powdered	lb.	.09½ – .10	.10¼ – .12
Sulphur chloride, yellow	lb.	.04½ – .05	.05¼ – .06
Sulphur, crude	ton	18.00 – 20.00	- -
Sulphur dioxide, liquid, cylinders extra	lb.	.08 – .08½	.09 – .10
Sulphur (sublimed), flour	100 lb.	- -	2.25 – 3.10
Sulphur, roll (brimstone)	100 lb.	2.00 – 2.15	2.20 – 2.70
Talc—imported	ton	30.00 – 40.00	- -
Talc—domestic powdered	ton	18.00 – 25.00	- -
Tin bichloride	lb.	.10 – .10½	.10¾ – .10¾
Tin oxide	lb.	- -	.39 – .40
Zinc carbonate	lb.	.14 – .14½	.14¾ – .15¼
Zinc chloride, gran	lb.	.06 – .06¼	.06¾ – .07
Zinc cyanide	lb.	.42 – .44	.45 – .47
Zinc oxide, XX	lb.	.07½ – .08	.08¼ – .08½
Zinc sulphate	100 lb.	2.75 – 3.00	3.05 – 3.30

Coal-Tar Products

NOTE—These prices are for original packages in large quantities f.o.b. N.Y.:

Alpha-naphthol, crude	lb.	$0.95 — $1.00
Alpha-naphthol, refined	lb.	1.10 — 1.15
Alpha-naphthylamine	lb.	.29 — .31
Aniline oil, drums extra	lb.	.16 — .17
Aniline salts	lb.	.22 — .24
Anthracene, 80% in drums (100 lb.)	lb.	.75 — 1.00
Benzaldehyde U.S.P.	lb.	1.25 — 1.35
Benzene, pure, water-white, in drums (100 gal.)	gal.	.30 — .35
Benzene, 90%, in drums (100 gal.)	gal.	.28 — .32
Benzidine, base	lb.	.85 — .95
Benzidine sulphate	lb	.80 — .85
Benzoic acid, U.S.P.	lb.	.72 — .75
Benzoate of soda, U.S.P.	lb.	.57 — .65
Benzyl chloride, 95-97%, refined	lb.	.25 — .27
Benzyl chloride, tech	lb.	.20 — .23
Beta-naphthol benzoate	lb.	3.75 — 4.00
Beta-naphthol, sublimed	lb.	.53 — .55
Beta-naphthol, tech	lb.	.23 — .25
Beta-naphthyla mine, sublimed	lb.	1.50 — 1.60
Carbazol	lb.	.75 — .90
Cresol, U. S. P., in drums (100 lb.)	lb.	.14 — .20
Ortho-cresol, in drums (100 lb.)	lb.	.18 — .22
Cresylic acid, 97–99%, straw color, in drums	gal.	.60 — .65
Cresylic acid, 95-97%, dark, in drums	gal.	.55 — .58
Dichlorbenzene	lb.	.06 — .09
Diethylaniline	lb.	.50 — .60
Dimethylaniline	lb.	.32 — .34
Dinitrobenzene	lb.	.20 — .22
Dinitroclorbenzene	lb.	.21 — .22
Dinitronaphthalene	lb.	.30 — .32
Dinitrophenol	lb.	.32 — .34
Dinitrotoluene	lb.	.22 — .24
Dip oil, 25%, car lots, in drums	gal.	.72 — .75
Diphenylamine	lb.	.54 — .56
H-acid	lb.	.72 — .75
Meta-phenylenediamine	lb.	.90 — 1.00
Monochlorbenzene	lb.	.10 — .11
Monoethylaniline	lb.	.95 — 1.10
Naphthalene crushed, in bbls.	lb.	.06 — .06½
Naphthalene, flake	lb.	.06½ — .07
Naphthalene, balls	lb.	.07½ — .08
Naphthionate of soda	lb.	.58 — .65
Naphthionic acid, crude	lb.	.65 — .70
Nitrobenzene	lb.	.10 — .12
Nitro-naphthalene	lb.	.30 — .35

Nitro-toluene	lb.	$0.15 —	$0.10
N-W acid	lb.	1.20 —	1.30
Ortho-amidophenol	lb.	2.10 —	2.15
Ortho-dichlor-benzene	lb.	.17 —	.20
Ortho-nitro-phenol	lb.	.80 —	.85
Ortho-nitro-toluene	lb.	.10 —	.13
Ortho-toluidine	lb.	.12 —	.14
Para-amidophenol, base	lb.	1.20 —	1.25
Para-amidophenol, HCl	lb.	1.25 —	1.30
Para-dichlorbenzene	lb.	.17 —	.20
Paranitroaniline	lb.	.72 —	.80
Para-nitrotoluene	lb.	.55 —	.65
Para-phenylenediamine	lb.	1.55 —	1.60
Para-toluidine	lb.	.85 —	.90
Phthalic anhydride	lb.	.35 —	.38
Phenol, U. S. P., drums	lb.	.26 —	.27
Pyridine	gal.	1.60 —	1.75
Resorcinol, technical	lb.	1.50 —	1.55
Resorcinol, pure	lb.	2.00 —	2.10
R-salt	lb.	.55 —	.60
Salicylic acid, tech., in bbls	lb.	.29 —	.30
Salicylic acid, U. S. P	lb.	.32 —	.34
Solvent naphtha, water-white, in drums, 100 gal	gal.	.27 —	.32
Solvent naphtha, crude, heavy, in drums, 100 gal	gal.	.12 —	.14
Sulphanilic acid, crude	lb.	.24 —	.26
Tolidine	lb.	1.20 —	1.30
Toluidine, mixed	lb.	.30 —	.35
Toluene, in tank cars	gal.	.25 —	.28
Toluene, in drums	gal.	.30 —	.35
Xylidines, drums, 100 gal	lb.	.40 —	.45
Xylene, pure, in drums	gal.	.40 —	.45
Xylene, pure, in tank cars	gal.	.45 —	....

Industrial

Financial, Construction and Manufacturers' News

Industrial Developments

GLASS—The Alliance Window Glass Co., Salem, W. Va., has arranged for the resumption of operations at its plant, giving employment to more than 150 men.

The Turner Brothers Glass Products Mfg. Co., Terre Haute, Ind., has resumed production in its bottle-manufacturing department, after an idleness of about 8 weeks. The company will give immediate employment to about 175 additional operatives, making a total working force of about 300 persons. It is expected to maintain capacity operations for an indefinite period.

The Salem Co-operative Window Glass Co., Salem, W. Va., has resumed production at its plant, after a curtailment for a number of weeks.

LEATHER—Tanneries at Wilmington, Del., are rapidly increasing their production schedules, and a number of plants have added to their working forces during the past few weeks. The Christiania Leather Co. has resumed operations after an extended curtailment on a basis of about 100 dozen skins per day; it is expected to increase this schedule to 200 dozen at an early date. The Standard Kid Mfg. Co. is running under heavy output, specializing in colored kid. The Amalgamated Leathers Co. is making machinery improvements and repairs and plans to resume active production at an early date. William Beadenkopf has opened his local glazed kid plant, giving employment to a good working force. The Union Leather Co. is maintaining active manufacture and expects to continue practically at capacity for an indefinite period. The Delmarvia Leather Co., specializing in the production of glazed kid, has recently resumed operations at its plant, with good working force.

The J. H. Ladew Co., Newark, N. J., is now running at about 80 per cent of normal, devoting the output to high-grade sole leather.

RUBBER—The Lambert Tire & Rubber Co., Barberton, O., has advanced production to about double that heretofore scheduled, and is now running on a basis of about 350 cushion tires per day. This is the second increase made in manufacture by the company since the first of the year. The working force has been materially enlarged.

The Hood Rubber Co., Watertown, Mass., is running under heavy capacity at its tire-manufacturing plant, giving employment to a normal working force. Unfilled orders on hand insure continuance on the present basis, it is said, for some time to come.

METALS — The Callahan Zinc-Lead Co., Cœur d'Alene, Idaho, is arranging for the immediate resumption of operations. The local mill is being made ready, with machinery and other repairs now nearing completion.

The Chino Copper Co., Silver City, N. M., is maintaining active operations at its local plant, giving employment to a large working force. Wages have been increased 10 per cent, effective Oct. 1.

The Utah Copper Co., Bingham, Utah, is advancing production at its plants in this section. The wage schedule has been increased for laborers and workmen 40 and 50 cents per day, respectively. Other wage advances for skilled men are expected to be made at an early date.

The American Steel Foundries, Inc., Chicago, Ill., has advanced production at its plants to about 80 per cent of capacity.

IRON AND STEEL—The Reading Iron Co., Reading, Pa., is continuing the resumption of production in its different plant departments and has now placed its local No. 1 puddling mill in service, following a suspension for almost 2 years. The plant has been completely rebuilt; it consists of 8 double furnaces and will give employment to about 150 men.

The National Tube Co., Pittsburgh, Pa., has blown in the fifth and last blast furnace at its Lorain, O., plant, placing the works on a 100 per cent operating basis for the first time in nearly 2 years.

The Shenango Furnace Co., Sharon, Pa., has blown in its No. 4 blast furnace, after a long period of suspension.

The Virginia Iron, Coal & Coke Co., Roanoke, Va., is arranging for the early resumption of its blast furnace at Max Meadows; the plant has been idle for more than 18 months. The company is also planning to blow in its other furnaces at Roancke and at Big Stone Gap.

The Bethlehem Steel Co. has blown in a fifth blast furnace at its Lackawanna plant at Buffalo, N. Y.

The Eastern Steel Co., Pottsville, Pa., is planning to blow in another blast furnace at its plant at an early date.

The Allegheny Ore & Iron Co., Irongate, Va., is planning to blow in its Buena Vista blast furnace before the close of the month.

The Wickwire Steel Co., Buffalo, N. Y., is completing the relining of a blast furnace at its local plant, and will place the unit in blast at an early date.

MISCELLANEOUS—The Edison Portland Cement Co., Edison, N. J., is running full at its local mills. A wage increase of 5c. an hour has recently been placed into effect, making a total advance of 60 per cent over the pre-war wage scale at the plant. About 600 employees are now on the payroll.

The U-Rub-It Chemical Co., Philadelphia, Pa., has completed the establishment of a new plant at 1208 South 23rd St., and has placed the factory in service on a full production schedule.

The Mexican Candelilla Wax Co., Torreon, Mexico, and a number of other candelilla wax-manufacturing plants in the States of Coahuila and Nuevo Leon, Mexico, have resumed operations after a shut-down for a number of years. The wax is extracted from the candelilla weed.

The Heyden Chemical Co., Garfield, N. J., manufacturer of salicylic acid, salicylate, etc., is completing the rebuilding of its local plant, destroyed by fire last year. The factory will be placed immediately in operation with a regular working force.

The Sherwin-Williams Co. of Canada, Montreal, Que., is advancing production at its paint and varnish plants. A 20 per cent increase has been recorded during the past year, as compared with the previous twelve-month.

Construction and Operation

Alabama

MOBILE—A 1-story foundry will be erected at the plant of the Mobile Pulley & Machine Works, to be equipped for the production of steel castings. Plans are being completed.

California

SAN FRANCISCO—The Los Angeles Soap Co., 633 East 1st St., Los Angeles, manufacturer of soap, washing powders, sal soda, etc., will take bids at once for the erection of a 2-story and basement plant at 2nd and Brannan Sts., San Francisco, estimated to cost about $80,000, including equipment. W. H. Crim, Jr., 425 Kearny St., San Francisco, is architect.

BERKELEY—The El Dorado Oil Co., University Ave. and 3rd St., will commence immediately the erection of a 2 story addition to its oil works, to cost about $13,000.

SANTA MONICA—The Santa Monica Brick Co. has construction in progress on a new plant at 24th St. and Michigan Ave., to be equipped for an initial production of about 40,000 bricks per day. The company was organized recently. M. J. Carlton is general manager.

HAYWARD—The Concrete Lumber Co., Los Angeles, has tentative plans under consideration for the establishment of a new plant at Hayward. A site will be selected at an early date.

Colorado

WHITE RIVER CITY—The Rio Blanco Carbon Co., 818 Symres Bldg., Erie, Pa., has plans under way for the erection of a new plant at Rio Blanco, White River City, consisting of three main buildings for carbon production, estimated to cost close to $75,000. O. D. Horton, 714 Commerce Bldg., Erie, is engineer. Thomas J. Dixon is president.

Connecticut

MILFORD—The Pruven Composition Products Co., recently organized under Delaware laws with capital of $250,000, is completing the remodeling of the local factory of the Askan Rubber Co., lately acquired, and will equip the plant for the manufacture of composition products, to be used as a substitute for hard rubber. It is expected to give employment to about 50 men for initial operations and this number will be increased at a later date. John J. Sharo is president.

Georgia

QUIMTAN — Construction has been commenced on an addition to the foundry at the plant of the Southern Machinery Co., to double, approximately, the present capacity. F. C. Underwood is president and general manager.

Kentucky

RUSSELLVILLE—The Independent Nitro Co., recently organized, has awarded a contract to John H. Berry, Union City, Ky., for the erection of a new local plant for the manufacture of nitroglycerine and kindred products. D. W. Kennedy, Richmond, Va., is president, and Stone W. Norman, secretary.

WILLIAMSBURG—The Iroquois Natural Gas Co., Iroquois Bldg., Buffalo, N. Y., is reported to be planning for the erection of a local plant for the manufacture of carbon black and kindred products, estimated to cost about $200,000, including machinery. Walter Simpson is president.

Louisiana

MONROE—The Monroe Glass Co., recently organized, has acquired property at Terminal Heights, a suburb of the city, as a site for the erection of its proposed new plant for the manufacture of blown glass products. The initial works will cost about $25,000, and are expected to be ready for operation by the close of the year. John Hartman, Alexandria, La., is vice-president in charge.

LAFAYETTE—The Peoples Cotton Oil Co., is planning for the rebuilding of the portion of its plant recently destroyed by fire. The new structure will be 150x200 ft. T. M. Biossat is vice-president and general manager.

Maryland

BALTIMORE—The United Lead Co., 827 South Howard St., has filed plans for the erection of a new 2-story building at its plant, 34x155 ft., estimated to cost about $40,000. The construction contract has been awarded to the Consolidated Engineering Co., Calvert Bldg.

Massachusetts

ALLSTON—The Atlantic Refining Co., 248 Boylston St., Boston, with headquarters at 3144 Passyunk Ave., Philadelphia, Pa., has awarded a contract to Metzger, Fisher & White, Otis Bldg., Philadelphia, for the erection of a new building, 2-story, 100x200 ft., at 52 Cambridge St., Allston, estimated to cost about $50,000.

SALEM—Baker & Kimball, 28 South St., Boston, have completed plans and will commence the immediate erection of their proposed new leather-manufacturing plant on property recently acquired at 5 Fort Ave., Salem, to be 2-story, 70x175 ft., and estimated to cost about $40,000.

Michigan

FLAT ROCK—The Ford Motor Co., Highland Park, is completing plans and will soon take bids for the erection of its proposed new plant at Flat Rock for the manufacture of sheet glass, for windshield and other service. It will be 1-story, 258x760 ft., and is estimated to cost close to $1,500,000, including machinery. Albert Kahn, 1000 Marquette Bldg., Detroit, is architect. The same architect is now taking bids for the construction of a new steel and steel alloy laboratory for the company at Dearborn, Mich.

Mississippi

CANTON—John T. Sharp, Jr., has preliminary plans under way for the establishment of a local plant for the manufacture of brick and affiliated burned clay products. Inquiries are being made for machinery and equipment.

Missouri

KANSAS CITY—The Vulcanite Roofing Co., 12th and Crystal Sts., manufacturer of composition roofing products, has construction in progress on a 1-story addition to its local plant, estimated to cost about $25,000. The company is a subsidiary of the Beaverboard Companies, Inc., Buffalo, N. Y.

MILAN—The City Council has plans in progress for the installation of a new filtration plant at the municipal waterworks.

New Hampshire

PLAISTOW—The Merrimac Clay Products Co., Inc., Room 609, 185 Devonshire St., Boston, Mass., will soon break ground for the erection of a new plant at Plaistow, for the manufacture of a line of burned clay products, to comprise a main 1- and 2-story works, 200x600 ft., estimated to cost about $250,000, including machinery. Morse & Chase, 25 Washington Sq., Haverhill, Mass., are architects.

New Jersey

EAST MILLSTONE—Fire, Oct. 2, destroyed a portion of the fertilizer mill of Fred Bascom, with other property in the immediate vicinity, resulting in a total loss of about $50,000. It is planned to rebuild.

JERSEY CITY—The Ault & Wiborg Co., 12th St., manufacturer of printing inks, etc., will make extensions in its tankage department at 307 13th St., estimated to cost about $12,000.

New York

PEEKSKILL — The Fleischmann Co., 701 Washington St,. New York, is taking bids for the rebuilding of the portion of its local yeast-manufacturing plant, recently destroyed by fire.

LONG ISLAND CITY—The Abbey Effervescent Salt Co., Inc., 1382 Broadway, New York, has leased a floor in the new building on Rawson St., near Queens Boulevard, Long Island City, for the establishment of a branch plant for the manufacture of effervescent salts and kindred specialties.

Ohio

AKRON—The Rote Leather Co., recently organized under Delaware laws with a capital of $1,000,000, has acquired the plant of the Doyle Rubber Co., near the city limits, erected about 2 years ago but never occupied. The new owner will commence immediately the installation of machinery for the manufacture of imitation leather products for automobile tops and other service, and purposes to have the works ready for operation by the first of the year. B. W. Rote is president, and J. W. Hildebrand, secretary.

LIMA—The Buckeye Casting Co., specializing in the production of gray iron castings, has construction in progress on a 1-story foundry addition, consisting of two adjoining structures, each 40x40 ft., estimated to cost about $75,000, including equipment. John Sonnerbaum is president.

NORTH AKRON—The International Lead Co., a subsidiary of the Anaconda Copper Co., 25 Broadway, New York, has completed foundations for its proposed new local plant for the manufacture of zinc oxide and affiliated products, and will commence superstructure work at once. The entire plant, with machinery, is estimated to cost in excess of $750,000.

Pennsylvania

TRAINER—The Sinclair Consolidated Oil Corp., 45 Nassau St., New York, will break ground at once for the erection of a new oil-refining plant at Trainer, near Chester, on a 300-acre site recently purchased. The initial plant will consist of a number of buildings, equipped to give employment to close to 700 operatives, with storage department to consist of 15 steel tanks, each of 55,000-gal. capacity. It will cost about $2,000,000, with machinery. At a later date it is proposed to extend the plant to practically twice the size, with aggregate investment to approximate $5,000,000.

PHILADELPHIA—The General Paper Products Co., 10th and Diamond Sts., is taking bids for the erection of a 2-story plant addition, 30x68 ft., to be located at 3430 Lancaster Ave. James C. S. Fernald, 5533 Wyalusing Ave., is architect.

PHILADELPHIA—The M. L. Shoemaker Fertilizer Co., Venango St. and the Delaware River, has completed plans and will commence the immediate rebuilding of the portion of its plant, recently destroyed by fire, estimated to cost about $100,000.

WHITE HAVEN—The Peerless Powder Co. is completing the erection of a new local plant, comprising a number of buildings, and purposes to commence operations at an early date. Employment will be given to about 100 persons.

PHILADELPHIA—The Franklin Sugar Refining Co. 125 South Orianna St., has acquired the group of buildings at Delaware Ave. and Reed St., heretofore held by the Spreckels Sugar Refining Co., for a consideration said to be $2,500,000. The plant will be used by the new owner for general production, providing necessary enlargements.

JEANETTE—The American Window Glass Co., Farmers' Bank Bldg., Pittsburgh, has awarded contract to the Heyl & Patterson Co., 51 Water St., Pittsburgh, for the construction of its proposed plant addition at Jeanette. The work will consist of a new 12-machine building and subsidiary departments, estimated to cost approximately $1,500,000. William L. Monro is president and general manager.

NEW CASTLE—The Grasselli Powder Co., Guardian Bldg., Cleveland, O., has commenced the construction of an addition to its dynamite-manufacturing plant at Covert Station, near New Castle, designed to double approximately the present capacity. The new extension will be equipped to give employment to about 100 operatives.

CASTLE SHANNON—The Pittsburgh Art Stone Co., 807 Jones Law Bldg., manufacturer of composition stone products, is taking bids for the construction of a new 1-story plant on local site, estimated to cost close to $30,000. D. C. Tabor is president.

South Carolina

GEORGETOWN—The former alcohol plant of the du Pont Powder Co., Wilmington, Del., was destroyed by fire, Sept. 26; an official estimate of loss has not been made. The plant has not been in operation for a number of months past, and it is not expected to rebuild.

Tennessee

CHATTANOOGA—The Abrasive Co., 30 Church St., New York, manufacturer of grinding wheels and other abrasive products, is reported to be planning for the construction of a new ore-reduction plant in the vicinity of Chattancoga. Raw material will be furnished from the company's mines at Adairsville, Ga. Henry M. Payne is consulting engineer.

Texas

EL PASO—The Tex-McCracken Concrete Pipe Co., 304 Trust Bldg., has plans under way for the construction of a new plant for the manufacture of concrete pipe and kindred products, on site selected on Stevens Ave., near Frutas St. It will consist of a number of buildings, and is estimated to cost approximately $75,000. H. E. Johnson is general manager.

HOUSTON—The Texas Tinners' Supply Co. is making inquiries for a quantity of machinery for the manufacture of seamless rubber products.

AMARILLO—F. J. Storm, Amarillo, and associates, are organizing a new company to construct and operate a gasoline extraction plant in the Amarillo gas field. A site has been selected and work will be begun immediately.

Virginia

GOSHEN—The Speer Sand Co. has plans under way for the construction of a new local plant for the manufacture of hollow cement blocks and other composition cement products. A list of equipment has been arranged. It is proposed to commence work at an early date.

Washington

TUMWATER—The West Coast Pulp & Paper Co., Salem, Wash., has acquired local buildings, heretofore occupied by the Phex Co., and will remodel the structure for the establishment of a new paper mill. Work will be commenced at an early date. C. M. Miall is president.

CONCRETE—The Superior Portland Cement Co. has awarded a contract to the Rounds-Clist Co., Walker Bldg., Seattle, for the construction of a 1-story plant addition, 125x250 ft., estimated to cost about $100,000.

West Virginia

WEIRTON—The Weirton Steel Co. has awarded a contract to the McClintic-Marshall Co., Oliver Bldg., Pittsburgh, Pa., for the construction of a new plant addition, estimated to cost approximately $1,500,000, with equipment. The work will consist of 12 new mills, for the manufacture of black and galvanized sheets; all equipment will be electrically operated. It is expected to have the plant ready for service early in May, 1923. D. M. Weir is vice-president.

Wisconsin

PORTAGE—The Ford Motor Co., Highland Park, Mich., is reported to be planning for the construction of a new zinc oxide plant in the vicinity of Portage, estimated to cost in excess of $500,000. The work will include a hydro-electric power plant to be located on the Wisconsin River. Preliminary surveys are in progress.

NEENAH—The Valley Paper Mills Inc., has awarded a contract to the Appleton Construction Co., Appleton, Wis., for foundation work for its proposed 1- and 2-story paper mill, 80x550 ft., on local site. Blair Springs district, estimated to cost about $100,000. Contract for superstructure will soon be let. G. W. Burnside is secretary and manager.

New Companies

THE DUCHARME CHEMICAL CO., INC., Bridgeport, Conn., has been incorporated with a capital of $20,000, to manufacture chemicals and chemical byproducts. The incorporators are Charles D. Boyd, John J. Hennessy and John G. Flood, 1400 Stratford Ave., Bridgeport.

THE ACKERMAN RUBBER CO., Paterson, N. J., has been incorporated with a capital of $250,000, to manufacture rubber products. The incorporators are L. M. and Wallace W. Seed, and Frank P. Ackerman, 39 Paterson St., Paterson.

THE NORTHWESTERN POTTERY CO., 5220 Norwood Park, Chicago, Ill., has been incorporated with a capital of $100,000, to manufacture earthenware products of various kinds. The incorporators are Richard C. Mazer, Edward C. Blanko and Albert W. Bookman.

THE ALBANY SOAP CORP., Albany, N. Y., has been incorporated with a capital of $90,000, to take over and merge the Three Points Products Corp. and the Christian Brothers Soap Co., both of Albany. The new company will manufacture soaps, washing powders, etc. The incorporators are J. H. Rea, J. Grober and J. Nicklas, all of Albany. The company is represented by Tobin, Wiswall & Walton, attorneys, Albany.

THE BENTON CHEMICAL CO., INC., 113 Water St., Baltimore, Md., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are Gordon Eaton, Eugene Frederick and Henry C. Meusel.

THE ROANOKE GLASS CO., Roanoke, Va., has been incorporated with a capital of $100,000, to manufacture glass products. R. H. Angell is president, and C. R. Williams, secretary, both of Roanoke.

THE M. D. OIL CORP., Rochester, N. Y., care of Albright & Mepham, E. and B. Bldg., Rochester, representatives, has been incorporated with a capital of $150,000, to manufacture oil products. The incorporators are B. and F. Seaman, and C. Clark.

THE WATKINS CHEMICAL CO., care of the Delaware Registration Trust Co., 900 Market St., Wilmington, Del., representative, has been incorporated with a capital of $200,000, under state laws, to manufacture chemicals and chemical byproducts.

THE BLACKFORD WINDOW GLASS CO., Vincennes, Ind., has been incorporated with a capital of $1,000,000, to take over and consolidate the Blackford Window Glass Co. and the Indiana Window Glass Co., both of Vincennes. The new organization will continue in the manufacture of sheet glass.

THE ARUNDEL SHOPE BRICK CO., Pier 2, Pratt St., Baltimore, Md., has been incorporated with a capital of $25,000, to manufacture concrete and cement bricks, blocks, etc. The incorporators are Lawson L. Wagner, Richard A. Froehlinger and Walter C. Mylander.

THE HITS-IT MFG. CO., Camden, N. J., care of the New Jersey Corporation Guarantee & Trust Co., 419 Market St., Camden, representative, has been incorporated with a capital of $125,000, to manufacture insecticides, chemical specialties, etc.

THE LONGLEY CHEMICAL CO., 6747 Chappel Ave., Chicago, Ill., has been incorporated with a capital of 201 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are John Longley, James A. Sell and Benjamin Kaufmann.

THE DENNY-MEXIA OIL CO., New York, N. Y., care of the United States Corporation

Co., 65 Cedar St., New York, representative, has been incorporated under Delaware laws, with capital of $5,000,000, to manufacture petroleum products.

THE CONCORD LIME CO., Concord, Tenn., has been incorporated with a capital of $10,000, to manufacture lime and affiliated products. The incorporators are H. G. and M. L. Winfrey, and O. L. White, all of Concord.

THE FALK CO., INC., Pittsburgh, Pa., care of Sachs & Caplan, 328 Frick Bldg., Pittsburgh, representatives, is being organized by Arthur C. Trask, Victor J. Poll and Louis J. Reizenstein, to manufacture oils, greases, tanning materials, etc. Application for a state charter will be made on Oct. 30.

THE CLIMAX OIL CO., care of the Corporation Guarantee & Trust Co., Land Title Bldg., Philadelphia, Pa., representative, has been incorporated under Delaware laws with capital of $1,500,000, to manufacture petroleum products.

THE COMMERCIAL TIRE CORP., Fort Wayne, Ind., has been incorporated with a capital of $75,000, to manufacture automobile tires and rubber accessories. The incorporators are Harold H. Bieber, C. Platt Squires and Morton M. Hathaway, all of Fort Wayne.

THE JOHN G. BEEKLER CO., 659 Hobbie St., Chicago, Ill., has been organized under state laws to operate a chemical research laboratory, manufacture chemical specialties, etc. The company is headed by Charles O. and Ralph Sethness.

THE PAN-AMERICAN PRODUCTS CORP., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, representative, has been incorporated under Delaware laws, with capital of $2,500,000, to operate a tannery and manufacture leather goods.

THE FLORIDA DEHYDRATION CO., Jacksonville, Fla., has been incorporated with a capital of $75,000, to construct and operate a local dehydration pant. Hugh S. Grainger is president; and M. H. Weaver, secretary, both of Jacksonvile.

THE BOYD OIL CO., care of the Corporation Trust Co. of America, du Pont Bldg., Wilmington, Del., representative, has been incorporated under state laws with a capital of $2,000,000, to manufacture petroleum products.

THE SENECA FOUNDRY CO., Waterloo, N. Y., care of W. S. O'Brien, Geneva, N. Y., representative, has been incorporated with a capital of $25,000, to manufacture iron, steel and other metal castings. The incorporators are J. and J. F. Madia, and C. Cannull, Waterloo.

LOUIS F. GUERRE & CO., INC., New Orleans, La., has been organized under state laws to manufacture waterproof roofing cements, paints, etc. The incorporators are Louis Guerre and Fitch H. Kelly, both of New Orleans.

THE PERFECT PRODUCTS CO., of Huntsville, Ala., has been incorporated with a capital stock of $100,000, to manufacture oxalic acid. The incorporators are T. W. Pratt (president the West Huntsville Cotton Mills Co.), Dr. C. A. Grote, W. S. Dillworth, Kenneth Martin and H. D. Rankin. The main office and plants are located at 415 Meridian St., Huntsville, Ala.

H. B. BERCOW & CO., 15 Park Row, New York City, has been incorporated with a capital of $20,000, to trade in chemicals and allied products. The incorporators are H. B. Bercow, R. Josephi and A. Arendt. The attorney is B. F. Kraft, 59 Wall St., New York City.

THE URADINA CHEMICAL CORP., New York, N. Y., care of the United States Corporation Co., 65 Cedar St., New York, representative, has been incorporated under Delaware laws with capital of $1,000,000, to manufacture chemicals and chemical byproducts.

THE SEABOARD FOUNDERS, INC., Brooklyn, N. Y., care of Fowler & Lesser, 126 Liberty St., New York, representatives, has been incorporated with a capital of $110,000, to manufacture iron, steel and other metal castings. The incorporators are R. J. West, J. C. Garrett and H. W. Eldred.

THE PACIFIC BRICK & TILE CO., 4600 Alhambra Ave., Los Angeles, Calif., has filed notice of organization to manufacture brick, tile and kindred burned clay products. The company is headed by Carl B. Gallasch.

THE CONSUMERS' OIL CORP., Union Hill, N. J., has been incorporated with a capital of $100,000, to manufacture oil products. The incorporators are Charles Killcast, George and Herman Koch, 575 Jefferson Place, Union Hill. The last noted represents the company.

THE ERCUTO CORP., Rochester, N. Y., has been incorporated with a capital of $50,000, to manufacture chemicals, dyestuffs and affiliated products. George B. Tucker, 110 Harvard St., Rochester, is the principal incorporator.

THE WEBB-DIMMITT OIL CORP., San Antonio, Tex., has been incorporated with a capital of $150,000, to manufacture petroleum products. The incorporators are M. L. Cummings, P. W. Carbusier and J. J. Laas, all of San Antonio.

Capital Increases, etc.

THE PENNSYLVANIA INDEPENDENT OIL CO., Allentown, Pa., has filed notice of increase in capital from $200,000 to $1,000,000.

Frederick M. Woolley has been appointed receiver for the AMERICAN DYE INTERMEDIATES CO., Newark, N. J.

THE AMERICAN SPONGE & CHAMOIS CO., 47 Ann St., New York, N. Y., has filed notice of increase in capital from $150,000 to $500,000, for proposed expansion.

THE CONTINENTAL MINES, LTD., Toronto, Ont., operating gold and silver properties and plants, is disposing of a stock issue of $1,250,000, a portion of the proceeds to be used for expansion, etc. R. C. Warriner is president.

THE PRESTON CHEMICAL CO., 180 4th Ave., Brooklyn, N. Y., has arranged for an increase in capital from $30,000 to $50,000.

THE BRIER HILL STEEL CO., Youngstown, O., is disposing of a bond issue of $10,000,000, a portion of the proceeds to be used for plant extensions. James B. Kennedy is chairman of the board.

A petition in bankruptcy has been filed against the STANDARD MINING & CHEMICAL WORKS, INC., Newark, N. J. The liabilities and assets are not stated.

New Publications

MELLON INSTITUTE OF INDUSTRIAL RESEARCH has issued Bull. 1, Bibliographic Series, which gives a list of the books, bulletins, journal contributions and patents by members of Mellon Institute of Industrial Research, 1911-1922.

PETROLEUM POSSIBILITIES OF CERTAIN ANTICLINES IN SOUTHEASTERN IDAHO. By Virgil R. D. Kirkham. Bull. 4, Bureau of Mines and Geology, State of Idaho, Moscow, Idaho.

WOOD-PRESERVING TERMS. By Ernest F. Hartman and E. F. Paddock. Published by the Protexol Corp., New York. Price $1.

ELECTRICAL HEATING REFERENCE DATA. Published by the Electrical Alloy Co., Morristown, N. J. This copyrighted publication embodies the experience and suggestions of an expert on electrical heating.

WATER-GLASS (A Bibliography). Compiled by Morris Schrero. Published by the Carnegie Library of Pittsburgh, Pittsburgh, Pa. Price 15c.

THE EFFECT OF IMPURITIES ON THE OXIDATION AND SWELLING OF ZINC ALUMINUM ALLOYS. A research bulletin, issued by the New Jersey Zinc Co.

TRADE STANDARDS IN THE PUMP INDUSTRY, recommended by the Hydraulic Society, 1922, and prepared by C. H. Rohrbach, secretary, 50 Church St., New York City.

IMPERIAL MINERAL RESOURCES BUREAU PUBLICATIONS: Vanadium (1913-1919), price 6d.; Quicksilver (1913-1919), price 1s.; Iron Ore (summary of information as to the present and prospective iron-ore supplies of the world), price 6s.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 192 Carbon Black—Its Manufacture, Properties and Uses, by R. O. Neal and G. St. J. Perrott; Bull. 199, Experimental Production of Alloy Steels, by H. W. Gillett and F. L. Mack; Tech. Paper 188, Corrosion Under Oil Films, With Special Reference to the Cause and Prevention of the After-Corrosion of Firearms, by Wilbert J. Huff; Tech. Paper 276, Safe Mechanical Equipment for Use in Shaft Sinking, by R. H. Kudlich; Tech. Paper 277, Application of the Geophone to Mining Operations, by Alan Leighton; Tech. Paper 285, Compressed-Air Illness and Its Engineering Importance, With a Report of Cases at the East River Tunnels, by Edward Levy; Tech. Paper 290, Inclusions in Aluminum-Alloy Sand Castings, by R. J. Anderson; Tech. Paper 292, Tests of Gas Masks and Respirators for Protection for Locomotive Smoke in Railroad Tunnels, With Analyses of Tunnel Atmospheres, by A. C. Fieldner, S. H. Katz and S. P. Kinney; Tech. Paper 302, Coal-Mine Fatalities in the United States, 1921, by William W. Adams; Tech. Paper 307, Permissible Explosives, Mining Equipment and Apparatus Approved Prior to March 15. 1922, by S. P. Howell, L. C. Ilsley, D. J. Parker and A. C. Fieldner; Tech. Paper 311, Factors in the Spontaneous Combustion of Coal, by O. P. Hood.

NEW BUREAU OF STANDARDS PUBLICATIONS (U. S. Government specifications): Circ. 82, For Linseed Oil, Raw, Refined and Boiled; Circ. 84, For Basic Carbonate White Lead, Dry and Paste; Circ. 85, for Basic Sulphate White Lead, Dry and Paste; Circ. 87, for Zinc Oxide, Dry and Paste; Circ. 88, for Leaded Zinc Oxide, Dry and Paste; Circ. 89, for White Paint and Tinted Paints Made on a White Base, Semi-Paste and Ready Mixed; Circ. 93, for Iron-Oxide and Iron-Hydroxide Paints; Circ. 103, for Water-Resisting Spar Varnish; Circ. 123, for White Floating Soap; Circ. 124, for Liquid Soap; Circ. 125, for Soap Powder; Circ. 126, for Salt Water Soap; Circ. 127, for Automobile Soap; Circ. 128, for Chip Soap; Circ. 129, for Ordinary Laundry Soap; Circ. 130, for Grit Cake Soap; Circ. 131, for Scouring Compounds (*a*) and (*b*), for Floors and Soap-Scouring Compounds (*c*); Circ. 132, for Hand Grit Soap.

OTHER BUREAU OF STANDARDS PUBLICATIONS: Sci. Paper 440, The Spectral Transmissive Properties of Dyes: Seven Permitted Food Dyes in the Visible, Ultra-Violet and Near Infra-Red, by K. S. Gibson, H. J. McNicholas, E. P. T. Tyndall and M. K. Frehafer of the Bureau of Standards, with the co-operation of W. E. Mathewson of the Bureau of Chemistry, price 15c.; Sci. Paper 443, Measurement of the Color Temperature of the More Efficient Artificial Light Sources by the Method of Rotary Dispersion, by Irwin G. Priest, price 5c.; Tech. Paper 211, Radiators for Aircraft Engines, by S. R. Parsons and D. R. Harper, price 50c.; Tech. Paper 212, Carbon Monoxide in the Products of Combustion From Natural Gas Burners, by I. V. Brumbaugh and G. W. Jones, price 10c.; Tech. Paper 214, Durability of Cement Drain Tile and Concrete in Alkali Soils (Third Progress Report, 1919-1920), by G. M. Williams, price 10c.

Coming Meetings and Events

AMERICAN GAS ASSOCIATION will hold its annual convention and exhibition at Atlantic City, Oct. 23 to 28.

INTERNATIONAL CHAMBER OF COMMERCE will hold its second general meeting in Rome, Italy, March 19-26, 1923.

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING will be held at the Grand Central Palace Dec. 7-13, with the exception of the intervening Sunday.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a 3-day national convention in New York, beginning Oct. 18. The general topic of the convention is "Economics of Industry."

TANNERS' COUNCIL will hold its annual meeting Oct. 19 and 20 at the Congress Hotel, Chicago.

The following meetings are scheduled to be held in Rumford Hall, Chemists' Club, 52 East 41st St., New York City: Oct. 20—Society of Chemical Industry, Grasseli Medal. Nov. 10—American Chemical Society (in charge), Society of Chemical Industry, American Electrochemical Society, Société de Chimie Industrielle, joint meeting. Nov. 17—American Electrochemical Society, regular meeting. Dec. 1—Society of Chemical Industry, regular meeting. Dec. 8—American Chemical Society, regular meeting. Jan. 5—American Chemical Society, regular meeting. Jan. 12—Society of Chemical Industry, Perkin Medal. Feb. 9—American Electrochemical Society (in charge), Society of Chemical Industry, Société de Chimie Industrielle, American Chemical Society, joint meeting. March 9—American Chemical Society, Nichols Medal. March 23—Society of Chemical Industry, regular meeting. April 20—Society of Chemical Industry (in charge), American Electrochemical Society, Société de Chimie Industrielle, American Chemical Society, joint meeting. May 4—American Chemical Society, regular meeting. May 11—Société de Chimie Industrielle (in charge), American Chemical Society, American Electrochemical Society, Society of Chemical Industry, joint meeting, May 18—Society of Chemical Industry, regular meeting. June 8—American Chemical Society, regular meeting.

German Reparations And the Chemical Industry

SOME years ago there was a question which agitated the American people: "How old is Ann?" The answers varied from $-\sqrt{3}$ to 1,087. New problems have come, but none with the same popular appeal. One question has, however, interested serious thinkers in recent months: "How much can Germany pay?" The answers vary more even than those to the earlier question. Individuals get so involved that they lose their perspective.

Therefore the speech of Sir REGINALD MCKENNA before the American Bankers' Association shone like a beacon light among the murky thoughts on this subject. The trouble with previous investigations, said the distinguished visitor, is that they have studied rather the question, "What wealth can Germany produce?" than "What amount can Germany pay as foreign debt?"

The ability to pay a foreign debt depends on two things: first, the extent of foreign investments and, second, the surplus of exports over imports. At the present time Germany has no export surplus. This is due to many circumstances, partly to the limiting of foreign markets on account of prejudice, tariff and embargo; partly to the loss of the productive areas, Silesia, Alsace-Lorraine, and the Sarre, which means inevitably more importing than formerly. But an export surplus is not now available for reparations.

Foreign investments Germany has, or rather the people of Germany have them individually. They have resulted largely from the sale of goods and of German marks in foreign countries. These investments could be sold to the German Government, which then could turn them over for reparations. Roughly a billion dollars could be realized. But is Barkis willin'? Would a German sell a foreign investment for German marks even with the mark more valuable in Germany than out of it? Sir REGINALD MCKENNA believes that he would. He believes also that if the demand for reparations should cease for three years after the foreign investments had been turned in, the mark would appreciate and that thereafter a definite annual payment could be made.

This is an economic message from a wise business man. There is no question that Germany should pay to the limit. The question is how can we get the most out of her. Sir REGINALD looks at economic facts dispassionately and therefore his message is timely. He dismisses the accusation that the German Government has not acted with firmness and good faith in taxing the people sufficiently, by saying that increased taxation does not increase foreign trade. Payment of reparations is possible only with increased foreign trade and an export surplus.

This has a significant message for all of us. No economic unit can be destroyed from this civilization without serious menace to every other unit. The whole structure is organically one, and a defection on the part of one injures all. This civilization is precisely analogous to the human body. The next fact to face is that Germany must be brought back to health not because of deserts or of misplaced humanity, but because if she dies we suffer severely and perhaps die too. A few years more of paralyzed Germany would be fatal and the only beneficiaries would be the speculators—the wolves of business.

So if we are to bring Germany back to health we must prepare for competition. More specifically, the American chemical industry should and must prepare for competition. A healthy Germany means an active chemical industry. There are happy examples of American firms which have competed with Germany under the most unfavorable conditions. It can be done. Is there enough of the pioneer left in the rest of us to do it?

The War Department Survey

AN OFFICIAL COMMUNICATION from the Medical Department of the Army announces that as a part of a comprehensive study under the direction of the Assistant Secretary of War an investigation will be made of sources of supplies needed in that department. Not only is the Medical Department concerned with the provision of the personnel necessary for the treatment of sick and wounded, but it is also charged with the supply of the necessary materials. Therefore it will be necessary, first, to undertake a careful determination not only of the items needed but of the quantity. Second, a roster must be compiled of the personnel skilled in the manufacture, inspection or purchasing of the various commodities and third, a study must be inaugurated of the facilities of the country to produce the essential and important items of supplies.

It is an effort to do beforehand what was attempted after the declaration of war in 1917. The plan is excellent, progressive, businesslike. It will have vital interest whether any national emergency arises or not. A survey of this kind gives a vast amount of valuable data which should be available not only to the War Department but to industry in general.

Take, for example, a simple list of the commodities needed in modern surgery and medicine, together with an estimate of the quantities which would be consumed in an emergency. Such a list would be very illuminating to the chemical industry of the country and would make available better and more extensive supplies of hundreds of articles. How many plants there are anxious to extend their field of manufacture, yet unable to determine certainly what products can be desirably

produced, and for what products there would be a consistent demand?

Other phases of the survey will doubtless be retained in the secret files of the War Department, and quite rightly so. A committee of the American Chemical Society would be appropriate to discover what chemists and chemical engineers in the country have had experience in the manufacture of the drugs and chemical products required for army medical work. Such a committee would be well equipped to weed out the ambitious youngster who had his eyes on high rank in case of national emergency and had overrated his ability and experience. The American Chemical Society is the appropriate medium through which action should be taken as far as the trained personnel for the production, purchase and control or inspection of these commodities is concerned.

The co-operation of the chemical industry, individually and collectivaly, will undoubtedly be assured the War Department in its far-sighted work. Our congratulations are extended to those responsible for its institution.

The Measure of Efficiency And the Creative Impulse

IN OUR Exposition number, issued August 30, appeared an article by WALTER POLAKOV, entitled "Measuring Administrative Efficiency." The author described the use of the now justly famous Gantt chart as an administrative aid. With a properly designed chart, the executive can follow the efficiency of man, machine or organization. In every chart the ideal or normal performance of the man or machine or organization is indicated by a line, and exactly parallel to it is the actual performance of the individual or unit. Thus, the man or the operator has before him the perfect performance and is striving constantly through interested effort to find what means can be adopted to lengthen the line of his own performance. So the chart can mean much more than a mere historical record of accomplishment; it conveys a definite message of inspiration. It appeals to and awakens the creative impulse in the operator. In satisfying that impulse it accomplishes the impossible, especially when the work is routine, for routine kills the creative impulse. Is it possible that here is a medium which would act as the leaven of modern industry, re-inoculating its mechanism with some of the old artisan spirit, which places achievement above returns and the task well done as the ideal of accomplishment? Perhaps!

But there are two great stumbling blocks that must be recognized and removed. The first is in the application of the principle itself. Unless such charts are installed by experts who are more than experts, men who are genuine humanizers with a keen insight into human psychology and human aspirations, the work will fall short. They must be very deft in their charting, for there is nothing more sterile than an idea of this kind which has missed fire. Charts which do not stimulate but draw only ridicule would be worse than none. Success on the part of real experts would lure imitators, and inevitably a wild yeast of dissatisfaction and distrust would spring up.

The second and even greater stumbling block in the way of such achievement is the cupidity of manufacturers. Such a system can be "sold" to an executive or to a board of directors on a basis of increased efficiency and decreased cost, but they would be inclined to ridicule the ideals which Mr. POLAKOV'S article suggests. They would think it got them nothing. That they are wrong would not alter the inevitable result, for without the sympathy and enthusiasm of the management the charts could only be efficiency charts. Even as such they are remarkable, but if the other were possible perhaps it would be the millennium.

A Chemical Ghost Story Without the Ghosts

IF, INSTEAD of Prof. HENRY E. ARMSTRONG, Sir OLIVER LODGE had written the original letter, we should have had a whole company of the ghosts of dead-and-gone chemists broadcasting over the Atlantic Ocean by this time. As it is, the best we can do is to give our readers the story, and let them supply the spirits.

It begins with a letter from Professor ARMSTRONG in which he asks about Dr. HENRY S. CARHART, who, in an address given in 1905 before the Electrochemical Society, mentioned two Dutchmen, VAN TREESTWIJK and DEIMAN, who did some work in 1789. He is writing on the general subject which includes this work, and he wants to get his early history straight.

The name CARHART sounded familiar to us, but we couldn't place it at the moment. The last issues of "American Men of Science" and "Who's Who in America" failed to enlighten us. But the previous issue of "American Men of Science" stated that Dr. CARHART was born in 1844, and was professor of physics at Ann Arbor. That was our cue, and straightway we repaired to the Chemists' Club in the hope of finding an Ann Arbor man. The first person we met was Professor WHITE of that university, who had arrived from Washington a few hours before and was leaving for Michigan within the succeeding two hours. Professor CARHART had died in California long ago, he said, but in reply to our question as to who might be informed about his work and his more particular interests and habits of research, he thought Professor HULETT of Princeton might know more than anybody else. They had worked together in Ann Arbor and were close friends. This was our second cue.

The next step would naturally be to write to Professor HULETT. But we had not the favor of his personal acquaintance, whereas we felt ourselves on terms of such friendship with his associate, Professor HUGH S. TAYLOR, as to seek a favor. So we ventured to ask him to ask Professor HULETT, if he would, to recall, if he could, the work of Professor CARHART and his reference to the two Dutchmen of 1789; and then to tell us about it.

Two days later the following letter was received from Professor TAYLOR:

> You are the fortunate victim of a curious coincidence. As I was reading your letter Dr. HULETT was preparing a lecture on electrochemistry, and was at that precise moment reading Section 328 of Volume I of Faraday's "Experimental Researches in Electricity." He was there reading of an article by Dr. PEARSON in the year 1797 published in *Nicholson's Journal*, Volume I, pp. 241, 299 and 349. This article, given by Faraday, deals with an experiment which had been previously carried out in a somewhat different manner by the two Dutchmen in the year 1789. Had it not been for this fortunate coincidence I am quite sure that neither Dr. HULETT nor myself would have been able to help you.

There's the story; now bring along your ghosts! Unfortunately they will not perform for us, and Professor ARMSTRONG is about the last one we could imagine as sitting in a circle in the dark, singing hymns, holding hands and listening while little Eva the Indian

Maiden inspires the medium to say that she is happy, very happy. And yet, observe these leadings: the timing of the visit to the Chemists' Club, the presence of Professor WHITE, the writing to Professor TAYLOR instead of to Professor HULETT, who was interested in another problem and would not have remembered if the letter had reached him at any other time except when he had open before him Section 328 of Volume I of Faraday's "Researches." Here we have everything to make up a ghost story except the ghosts.

Salt Baths For Heat-Treating

EVERYONE knows the difficulty of heating a piece of steel to a red heat without a certain amount of oxidation—scaling or coloring—on the surface, be the heating and quenching ever so brisk. The same damage follows annealing operations, the longer time required offsetting the reduced activity of lower temperature. Such difficulties become very real indeed when one heats high-speed tools of very intricate design to just under their melting point, or fine wire (which is nearly all surface) to quite moderate temperatures. Again, delicate and expensive engraving on dies requires that such pieces be hardened without the least scaling or decarbonization.

For such work the strictest control of furnace atmospheres is required. Heating in a forge fire is of course out of the question; the best muffle furnace is none too good. Many good heat-treaters argue that the gas-fired furnace is better than those electrically heated because a "neutral" atmosphere can be more readily obtained when a violet flame is permitted to blow out the door and the gas and air are regulated for a "hazy heat." But "atmospheres" are something we don't know a great deal about, and they are very likely to play tricks on the operator—like the one who packed some tools in charcoal and annealed them just below the transformation range for several hours, only to find the surface decarbonized!

For all these reasons, metallurgists have used liquid baths of various sorts for their heating operations. Oils are suitable for low temperatures, white metals for intermediate, and lead or salts for rather higher ones. Their function is to heat the metal uniformly at a rapid rate and entirely out of contact with air. Naturally they must not react with the metal—either corroding, pitting or decarbonizing it, discoloring the surface or sticking to it so that they cannot be easily rubbed or washed off. If the bath is of salts, they must be of a nature that traces of salt escaping the washing operation will not accelerate corrosion or cause other damage. The bath evidently must have a melting point 150 deg. or so below its working temperature; it should not throw off poisonous or corrosive fumes if superheated—for that matter, copious fumes of any sort are objectionable and involve rapid wastage. It must be stable, both hot and cold, and not attack its containers. Finally, it should leave only a thin protective film on the hot steel being transferred to the quenching bath.

Such an array of requirements is so long that one would almost despair of finding a molten bath which will fill them all—especially if it is to operate over a wide range of temperature. Nevertheless the problem has been attacked, and at present several mixtures sold under trade names are available. No one of them will do everything, but it is believed that an intelligent selection will provide a set of three or four baths which will cover the range 500 to 2,100 deg. F. in a satisfactory manner. In view of the many requirements of a good salt bath, it will doubtless be easier and cheaper for the user of small quantities to standardize on some satisfactory brand, rather than make his own.

R. B. SCHENCK and SAM TOUR have recently read interesting papers before the steel treaters, respectively discussing the art of heat-treating in lead and recounting some experiments with salt baths. Several eutectic mixtures of salts having low melting points are noted in the literature, and a number of them were tried by Mr. TOUR. In general, it was found that carbonates will either decarbonize tool steels or coat them with an immovable black layer, while sulphates (often in very small percentages) corrode metals rapidly. Nitrates oxidize the steel if operated above 800 deg. F. Satisfactory tempering baths working below this figure may be made of sodium and potassium nitrates (molecular ratio 1 to 1) or a similar mixture of sodium nitrate and nitrite. Charcoal and cyanides must be kept away from these nitrate baths, on account of the explosion hazard.

Mixtures of chlorides are ordinarily used for hardening baths. A eutectic mixture of calcium and sodium chlorides (72.5 per cent $CaCl_2$ by weight) melting at about 950 deg. F. is sold under different names. Such a mixture made of commercial salts must be heated to 1,600 or 1,700 deg. F. several times, else it will pit the steel. Furthermore, this pitting action persists if the salt is contained in a graphite pot! However, calcium chloride should be avoided because it is hygroscopic and a rust promotor—any fume which condenses in the building becomes sirupy and rapidly corrodes iron fixtures. Heat-treated articles must consequently be carefully scrubbed in hot sal soda and rinsed in water, to remove the last traces of the salt.

The Ford Motor Co. makes extensive use of salt baths operating at about 1,550 deg. F. for heat-treating gears. As originally made up it consists of 50 per cent sodium carbonate, 37½ per cent sodium cyanide and 12½ per cent sodium chloride. Apparently the oxidizing power of the carbonate and the carburizing tendencies of the cyanide counterbalance each other. Cyanide appears to decompose, by an obscure reaction, when its temperature reaches about 1,500 deg. F.; a bath which previously was quiet then acquires a vigorous, continuous circulation. This is of the greatest value in keeping the temperature uniform throughout the bath, even though it costs a handful of fresh salt at intervals.

Barium chloride has not the pronounced disadvantage of being so volatile, hygroscopic and a rust promoter, but it possesses a melting point (about 1,700 deg. F.) too high for any quenching baths except high-speed steel. Sodium chloride also appears to be quite harmless, when free from magnesium sulphate. A eutectic mixture of NaCl and $BaCl_2$ (containing 22 per cent of the former by weight and melting at 1,175 deg. F.) is probably the best home-made, high-temperature bath. Sodium chloride fumes badly at high temperatures; pure barium chloride may then be used.

As mentioned above, we now have some salt mixtures which will operate over limited ranges of temperature, and will be found to do excellent work in continuous operation. What is yet to be found is a mixture which will work satisfactorily on batches—that is, receive the work at a temperature below that which causes appreciable scale in the open air, say 1,000 deg. F., and be heated gradually to the annealing or quenching temperature. This slow heating is especially necessary on parts where growth, shrinkage and warpage must be eliminated.

Readers' Views and Comments

Technology of the Carbon-Electrode Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—In one of a very interesting series of articles regarding "The Technology of the Carbon-Electrode Industry," Charles L. Mantell in your issue of Aug. 23 makes a statement regarding the future developments of this industry. He draws attention to the fact that the National Carbon Co. is manufacturing 24-in. electrodes 180 in. long, which he believes to be the largest ever made.

In an article printed in your journal of June this year the writer was able to show that Söderberg self-baking electrodes are in operation in Europe in sizes up to 39 in. diameter and about 230 in. long. The weight of these electrodes are three to four times the weight of the mammoth electrodes of the National Carbon Co.

Söderberg's jointless electrodes have been in continuous operation in Norway during more than 3 years, during which time about 420 ft. of one electrode has been consumed in the furnace. These facts give a further look into the future of the carbon-electrode industry than Mr. Mantell has been able to offer. The "black art" is about to lose its secrecy through the possibility of affording every electric furnace man the opportunity of making his own electrode in the very furnace where the same is being used. M. SEM.

Christiania, Norway.

Chemists in Public Life

To the Editor of Chemical & Metallurgical Engineering

SIR:—Having followed with more than passing interest the various articles on "Chemists in Public Life," I think the articles of Mr. Bolling (Sept. 6) and Mr. Cornell (Sept. 27) have digressed widely from the original point in view. I should like to ask of your readers who employ industrial chemists and analysts how much opportunity they give them to participate in any public matters that would take them, even for a day, away from their laboratory.

Having had charge of laboratories in several large industrial corporations, I have found as a general rule that they will employ as a head chemist as low a salaried man as they think can possibly get away with the work and give him as few cheap assistants as possible. In return, they expect him to develop quick, accurate routine methods for control, do research work and improve processes, analyze and pass upon all raw materials and finished products. In other words, a responsibility is placed upon him as great as any in the factory.

Most chemists will conscientiously try to do what is required. In order to do this, they must work out methods after hours, digest a quantity of chemical literature to keep up with the rapid progress of the science, attend society meetings, etc. When do they get the opportunity to interest themselves in public life? Only a few corporations give their chief chemist a place on their executive council. He seldom knows what improvements or changes are contemplated. Then, at a moment's notice, he must select materials and work out new methods. Oftentimes he does not know the exact purpose for which the raw materials are to be used and is given no opportunity to follow through the process. If he insists upon knowing and seeing just how the materials are used, he is often told his place is in the laboratory; they can take care of the manufacture and he is only "butting in" and interfering with production. Still, if the material fails, he is responsible. Just about the time he has routine methods established and has broken in an assistant on whom he can rely, the assistant leaves, because he cannot obtain the salary he has become worth.

Then a Mr. Cornell comes along with a rush analysis involving $1,000 or $10,000 worth of material. The chemist knows that if the material is not up to specifications he will have to buck the laboratory of the manufacturer. He knows he will have to be right and he knows that a correct analysis cannot be made inside of 3 days, and it is wanted in 3 hours. If he rushes through an analysis and is wrong, he loses his position and, what is more, his reputation. A good chemist simply cannot be rushed beyond the degree of accuracy he knows he must attain.

I have found chemists as a rule to be just as human and just as much interested in public affairs as any other class of men. Mr. Bolling may prefer pure science, and the pure scientist has his allotted part in the general advancement of the world, but I do not think his ideas are representative of chemists as a whole.

What Mr. Redman says (Aug. 16) about applications from students for laboratory work is undoubtedly true. But after they are employed in the laboratory, do they have the opportunity to see and know what their work pertains to and become interested in applying their technical knowledge at some point of production or manufacture? Or are they so rushed with routine that their only thought is to catch up with the mass of work ahead and get enough experience to go somewhere else and obtain a better position?

At one time I was in charge of a laboratory for a company which made a practice of starting a man on routine laboratory work, fitting him technically for a plant position, and then giving him an opportunity to make good. Of many, only one man refused to leave the laboratory and only one failed to make good in an executive position in the plant.

It is not the chemist who makes a hermit of himself, but the manufacturer who forces the chemist to become a hermit. Let those who employ chemists give them a business standing with the company in accordance with the value of their work, give them an opportunity to meet, associate and consult with executives and they will soon discover that their most valuable executives have been drawn from the technically educated men who may have started in the laboratory.

Once the chemist feels that he dare leave the laboratory for a few hours without things going wrong, that he can afford to attend a public meeting in place of a chemical one, that he does not have to eat, drink, sleep and think chemistry 24 hours a day in order to keep a

laboratory going that is woefully undermanned and underpaid, he will gladly interest himself in public life and no doubt prove as efficient there as he already has in industrial work.

Research Chemist for the
Federated Engineers Development Corporation.
Jersey City, N. J.

Proteins and the Theory of Colloidal Behavior

To the Editor of Chemical & Metallurgical Engineering

SIR:—Replying to the letter of Dr. John Arthur Wilson in your issue of Sept. 27, I can only ask that those interested read Dr. J. Loeb's book and then read my criticism of it published in your issue of Aug. 23. Some of the questions involved will also be treated more at length in my forthcoming A.C.S. monograph on Glue and Gelatin. Dr. Wilson's statement that I have "failed to grasp Loeb's ideas" is in a way a comment on the book, because throughout my criticism, to avoid possibility of error, I quoted Loeb's own words.

Though I had selected ten points for adverse comment, Dr. Wilson takes up only one, saying that "Loeb's theory is quite independent of this assumption [that gelatin is a definite chemical entity]; it assumes only that a highly ionizable chloride of gelatin is formed when gelatin is brought into contact with an aqueous solution of hydrochloric acid," etc. To the ordinary chemist the statement that gelatin forms gelatin chloride and sodium gelatinate involves the assumption that gelatin is a definite chemical entity—otherwise we might talk of apple pie chloride and sodium tobacconate; and this assumption is with others involved in the Donnan theory of membrane equilibria, the applications of which, by Prof. H. R. Proctor, Dr. J. A. Wilson and their followers, have been supported and praised by Dr. Loeb. To those acquainted with the literature, it seems that gelatin is not a definite chemical entity—see, e.g., Bogue's recent book.

All theories must perpetually run the gantlet, and one adverse fact may bring destruction. The upholders of the theory cannot then take the position of the Irishman who, when confronted by a witness of unquestionable character who saw him steal the pig, said: "Sure, that's nothing. I can bring in twenty men who'll swear they never saw me take it."

Far be it from me to deprecate the excellent work done by Professor Proctor, Dr. Wilson, Dr. Loeb and their co-workers, even though I may take exception to some of their details and conclusions. And much praise is due to the Gallun Co., with which Dr. Wilson is connected, for its generous support of the work of Prof. A. W. Thomas and others at Columbia University. But when Dr. Loeb says (p. 278): "There is only one source of colloidal behavior—namely, the Donnan equilibrium—at least as far as the proteins are concerned," it is time to stop and consider. There comes to mind such a possibility as gelatin having a more or less definite average adsorptive surface which need not be identical with the possible stoichiometric surface.

Dr. Wilson, in speaking of "the flight of imagination of those who have tried to dodge the mathematics of the Donnan equilibrium," falls into the very pit warned against in my criticism: "The great danger in applying mathematics to chemical and physical problems lies in the fact that we may be blinded by the logical perfection of this mere tool and make erroneous assumptions, or else neglect important factors that so often crop up unexpectedly in nature." It is not the algebra and calculus to which exception is taken, but the chemical and physical assumptions which underlie them, and without which they could not function or exist.

JEROME ALEXANDER.
New York City.

EDITOR'S NOTE—We knew there would be trouble a year and a half ago when, at the Chemists' Club celebration, Dr. Loeb brought out his observation that, so far as proteins were concerned, the measure of adsorption may be determined by hydrogen-ion concentration. This seemed to indicate that the so-called phenomena of adsorption are really chemical phenomena rather than a kind of colloidal plastering—at least, so far as proteins are concerned. It is the thesis of his important and very interesting book.

His findings are contrary to the conclusions heretofore current in regard to colloids, and many chemists who have worked long and ardently within the domain of colloid chemistry feel that Dr. Loeb must be wrong. They stand pat on earlier observations and conclusions. Among these we may include Mr. Alexander. Dr. Wilson, among others, thinks Dr. Loeb is right and that he has blazed the trail to great enlightenment in this work. Each expresses his opinion with some gusto. We shall close the discussion in these columns for the present by leaving it open.

Inadequacy of German Press Subsidy

The German press, which has weathered numerous financial and economic difficulties in the past year, has succeeded in obtaining only partial relief through the passage of a subsidy law effective July 21, 1922, says *Commerce Reports* of Oct. 2. The hopes of receiving immediate financial assistance, which it was thought this new relief measure would provide for, have been shattered. It is stated that it will be months before the proposed machinery will be in operation, which, of course, will be too late to prevent many papers from closing down. The press also complains that the funds which are to be raised by this subsidy will be wholly inadequate for their needs. For instance, the German press is to receive 1½ marks per thousand on all export sales of print paper, but this income alone would amount to only 223,570 paper marks for the month of June, 1922, to be distributed among all German newspaper publishers. The application of this export tax at the present time is somewhat vague, as it will also possibly include paper pulp and pulp timber; however, the sum to be realized will be insufficient.

Originally it was proposed by the federal government that the various German states establish an emergency fund (*Notkasse*) whereby a tax of 8 marks per person was to be assessed, raising a fund of approximately 500,000,000 marks for the assistance of the press. This did not meet with the approval of the several states, so the Rueckverguetungskasse für die Deutsche Presse (reimbursement fund for the benefit of the German press) described in the law was established. The German press has also strenuously opposed the exportation of print paper, which is greatly needed at home. They have not, however, succeeded in obtaining a more stringent export prohibition.

As the proposed assistance is not immediately forthcoming and the relief fund will be very small, the German newspapers are compelled to increase subscription and advertising rates in order to meet their increased costs of printing, labor, freight, ink and paper.

European Conditions as I Saw Them

Impressions of Casual Travelers Are Not Always Safe Criteria of True Industrial Conditions — Smokeless Chimneys Do Not Mean Idle Power Plants — Examples of German Industrial Competition and Its Effect on Business in Other Countries

By J. S. Negru

IN A previous article I outlined what I regard as the fundamental cause of the turmoil now prevailing in all European industrial countries and particularly in Germany—namely, that the Germans have lost the economic war which they have been waging for nearly the past 3 years against all the other industrial countries. This is a sweeping statement as to cause and effect, and so different from those made by the Germans themselves, by casual travelers and by omniscient personages here and there, that strong proofs are required before it can be accepted.

No doubt many others would arrive at the same conclusion as I have were they to give due thought to an analysis of the question, What has become of the fruits of Germany's very intensive and steady production during the past 3 years? For the benefit of those who do not feel disposed to undertake such an arduous task, I will endeavor in what follows to point out some of the striking facts that contributed to my conclusion.

Misleading Impression

Impressions of Germany from casual travelers are now regarded as good copy by newspapers and literary magazines. Many of them carry in each issue more or less of this material, and even some technical papers get hold of it and print it in good faith. But the trouble with most of this material is that it represents one or two isolated observations which are not typical of general conditions, although assumed to be such. As an example I may cite the following fact, which, had it come to the notice of the casual traveler, would have given another twist to his impressions.

On March 16, 1922, I went to the office of H., located on the corner of Friedrichstrasse and Leipzigerstrasse, Berlin, which as to traffic can compare somewhat with that of New York City at the corner of Broadway and 42d St. In order to cross Friedrichstrasse I had to pass a temporary wooden crossing, as the street was all torn up, a subway being built, the roof of which was at most 3 ft. from the surface. The first impression I got from this sight was much to the advantage of the municipal government of Berlin, which, I thought, although confronted with the fact that citizens were struggling for the necessities of daily life, was still able to get together large sums for public utilities. The impression was fine.

Corrected Impression

On the 18th of May, two months later, after having visited other German, Belgian and French districts, I was again in Berlin and made another trip to the above-mentioned office. The temporary wooden crossing was still there, the street was torn up as before, and the few workmen that I could see on both sides of the crossing—I counted six—were busying themselves in a way that reminded me of a high-speed movie film slowed down in order to give opportunity to observe every detail. And as for my first impression that Berlin was still keeping up with public improvements and the construction of public utilities—it naturally died. I soon learned that the street had been torn up for a long time prior to March 16, when I first saw it, and that although the actual cost of filling that part of Friedrichstrasse until the city could again get money with which to continue its work would be relatively small, they preferred to impress the casual traveler with the fact that Germany was not neglecting the public utilities. This is a typical example of how badly misled the casual traveler can be when writing about Germany after a single hurried trip across the country.

Wrong Impression

It might not be out of place to cite here a typical example of the comments of some traveling impressionists.

I have before me a pamphlet which is an advance copy of a paper on European Economic Conditions, 1921-1922, by C. J. Warren, of the Remington Typewriter Co., presented May 11, 1922, at the National Foreign Trade Convention at Philadelphia. In this pamphlet, which was released for afternoon papers May 11, Mr. Warren states under the heading "Germany," page 2, that "I made it my business to note the number of chimneys smoking, and to size up in a general way the various industrial districts in that country." He goes on to say how remarkably close to the official figures was his personal guess of the present percentage of German pre-war production, all based on the assumption that smokeless chimneys imply idle plants.

Smokeless Chimneys Do Not Mean Idle Power Plants

I am sure that Mr. Warren could have seen in Germany thousands of chimneys not smoking, but he and those who listened to his address or read it in the press must not forget that smoking chimneys make a very poor showing for good power plants. And we all know well that there are many excellent power plants in Germany. Ringelmann's smoke chart may still find some use in minor power plants located in this country, but few, if any, of the German plants need it now. One must not draw the conclusion that boilers are not steaming merely because stacks are not smoking.

So much for impressions and impressionists.

Plan of Preliminary Trips

By giving a brief outline of my trip I will better enable the reader to follow my work while in Europe.

I arrived in Belgium on Feb. 22, 1922, and on the following day had my first interview with Octave Lepersonne, general secretary of the Association of Engineers Graduated From the University of Liége. Being myself an alumnus of this school, it was logical that I should start where I felt most at home. In the course of many long conversations with Mr. Lepersonne I obtained a preliminary impression of the industrial

This is the second of a series of articles by Mr. Negru on this subject, the first of which appeared in last week's issue.

and economic situation in Belgium. Further interviews with many other Belgian engineers and economists, and with Samuel Cross, acting commercial attaché of the United States at Brussels, served to corroborate or correct the impressions already received. Thus I was enabled to outline a plan for making personal observations and reaching my own conclusions. A similar method was followed in France, Italy, Switzerland and Germany, consuming my time until April 5, when I was back again in Belgium.

Main Reasons for Changing the Plan for Subsequent Trips

According to my original plans made in New York City, immediately after completing the preliminary trip just outlined I was to devote my attention to certain well-defined points, prepare articles on specific subjects while still in Europe, and make only casual trips into Belgian and other industrial districts. But while I was still in America I was quite unaware of the condition in which I would find central Europe, and consequently could not foresee that I was soon to become quite skeptical of the much-heralded European researches, great industrial improvements, and the like. Nor could I foresee that what I was really to gain during this preliminary trip was a group of impressions somewhat hazy and occasionally quite contradictory. The few impressions of which I was absolutely certain at the close of my preliminary tour were so striking, but also so devoid of what might be called legal proof, that they needed further study in the hope of gathering proofs that could be safely accepted as indisputable.

Final Plan Adopted

Accordingly I decided to cover again somewhat the same route, conferring with some of the persons I had already met, in an effort to confirm my personal preliminary impressions. Furthermore, I wanted to get in touch with other individuals with whom, I had discovered in the meantime, it was well for me to talk. This plan was carried out, but only for Belgium, France and Germany. A second trip was not made into Italy and Switzerland. In addition I had also the opportunity to visit plants in Belgium, France and Germany. I also took part in the excursions of the Société de l'Industrie Minérale de France in the French war-devastated districts, visited the Ludwig II potash mines and works at Stassfurt in company with a group of members of the Society of German Metallurgical and Mining Engineers, assisted at some of the meetings of the Verein Deutscher Chemiker and at their exposition Achema III (Ausstellung für Chemisches Apparatewesen) on the occasion of the annual general meeting in Hamburg. Finally, I took quite an active part at Liége in the Congress of Engineers Graduated From the University of Liége, and often visited their exposition during the latter part of June and first part of July. This occupied the remainder of my time in Europe until Aug. 10, the date of my sailing for America on the steamer Lapland.

Substantiating My First Impressions

It was during these latter months that I was able to get additional information which, when correlated with that obtained on my first trip, comprised the sum total of what I learned while in Europe.

As an example of how the subsequent trips enabled me to get more substantial impressions, I may cite the following: When I left Switzerland on March 14 I knew that Swiss industry was suffering much from German competition. Thus on May 30 I wrote in my diary, among other items, one about my meeting with Mr. G., a German jewelry manufacturer who was producing as rapidly as possible wrist watch locks at a cost of 15 marks apiece. These locks were sold at 80 marks apiece to a friend of his in Chaux-de-Fonds, the very center of the Swiss watch industry, whence they were exported to Sweden at 2.5 Swiss francs (over 150 marks) apiece. The explanation given for this circuitous transaction was very simple:

The Chaux-de-Fonds district enjoys a world-wide reputation as a watch-making center, hence a product from this district can find more readily foreign markets. The large amount of 80 marks he got for his 15 marks product is the result of a mutual understanding between old friends. The German manufacturer could not sell direct to Sweden because the latter is the customer of the Swiss watch manufacturer. But by selling through the Swiss dealer the German was not only able to get rid of his wares but also received in return therefor Swiss francs, which are not debased in value like the German marks.

I have no doubt that the German manufacturer regarded this as a perfectly normal and legitimate business transaction, just as he probably felt that the wage of 4.5 marks per hour, then less than 1.5 cents, which he paid to the girls in his shop, was very good for that kind of work. And as for the Swiss maker of wrist watch locks, one can readily imagine how he would fare in his beautiful Switzerland with this kind of German competition.

A Typical Example of the German Economic War Policy

Another case which brings us much nearer home is that contained in a letter from one of our American subscribers who asked me to look into a certain matter while in Europe. I quote as follows from his letter:

"We are vitally interested in knowing why the manufacturers of the equipment required for the production of chemical pulp, principally soda or sulphate, can deliver all of the machinery required for a 30-ton daily capacity pulp mill at Madras, India, for one-fifth of the amount we must receive for American-made equipment of similar design. We feel that the matter of exchange between the countries affected is not alone responsible for this, and we wish you would have your Mr. Negru investigate the true conditions which are responsible; also have him ascertain, if possible, whether contracts taken by German firms are actually filled."

The German economic war policy, outlined in the previous article, explains clearly why the Germans offered machinery for one-fifth of the amount Americans must receive. As to whether contracts taken by German firms are actually filled, that is a question of the individual firm. The impression prevailing in Belgium and in France is that few importers are now putting much faith in the business promises of German industrials and merchants, even when such promises are given in writing.

Other articles giving Mr. Negru's impressions of conditions in Europe will be printed in subsequent issues.

Handling the Finished Products of Industry—VII

What to Observe When Studying an Existing Handling System With a View to Applying the Methods There Used in Another Plant—How These Points Are Illustrated by the Systems Described in This Series—Suggested Procedure in Layout of New Systems*

By Graham L. Montgomery

IT WAS STATED in the first article of this series that the material-handling equipment available today for handling finished products brings results to those who use it which warrant study by those still using manual handling methods. These results justify the statement that the use of automatic equipment for handling finished products is a necessity for those who wish to keep costs low for competitive reasons and still to make a fair profit.

This series covers but a small part of the range of process industries where mechanical handling methods can be used. By no means all of these industries present examples of material handling worthy of study. The examples which are presented serve to demonstrate clearly the important points to be observed in such a study. We shall list these points and show how their observation can be made of service in the consideration of prospective installations of handling systems.

From time to time other articles will appear in *Chemical & Metallurgical Engineering* which will describe good handling methods for finished products and illustrate the principles laid down in this series. But enough ground has already been covered to make it worth while to pause and determine the benefits which may be derived from such studies as we have been making.

Principal Advantages Derived From Finished Product Handling Systems

Handling equipment is obviously of advantage to those who use it, or its use would not be continued. The sane business man places no equipment in his plant from æsthetic considerations. Each piece of apparatus must earn its keep. It is only reasonable to suppose that the advantages derived by the present users may also be realized by many others who do not as yet use this equipment.

There are many advantages which automatic handling of finished products gives. Of these there are three which appear in every system. These are:

1. The amount of non-productive labor is decreased.
2. The speed of the product in its movement through the plant is increased.
3. The burden of management is decreased.

If, in the attempt to decide whether or not to install a material-handling system, a study is made of existing installations in similar industries, these three points should be kept in mind. The study should be made with a view to determining how and to what extent these advantages are attained in the installation studied and whether the means by which they are obtained can be applied elsewhere.

How to Study Existing Handling Systems

The key to all handling systems is the flowsheet. As a method of procedure, then, a flowsheet should be drawn for each handling system which is to be studied, starting at the point where the manufacturing process is completed and tracing out the path that the product is to follow from that point until it leaves the plant. These flowsheets should be drawn in both plan and elevation. From them can be determined whether the product flows in a straight and continuous manner and whether the system used is the most economical possible.

The flowsheet plan will show the path the product flows, bringing out any crossings, interferences or breaks in the flow. The flowsheet elevation shows the amount of power required to operate a system as compared with any other system by giving a measure of the lifts. This elevation also shows the advantage taken of gravity flow. On these considerations rest the comparative simplicity and economy of a handling installation. The fewer the steps in which the handling is accomplished, the straighter the flow, the more use that is made of gravity flow, the simpler to control and cheaper to operate will be the system.

Where to Seek a Decrease in Non-Productive Labor

If we consider a handling system in which no mechanical equipment is employed, the most noticeable thing about it will be the large amount of labor which it requires as compared to the labor used in actual manufacturing processes. If mechanical equipment is installed to accomplish this handling there will be one of two possible results obtained: Either the same amount of product is turned out with less labor, or more product is obtained from the same amount of labor.

As an example of where these decreases in non-productive labor may be looked for, refer to the third article of the series, dealing with soap handling. It will be noticed that in the plants cited the saving in non-productive labor made varies from 30 to 50 per cent. In both of these installations, the soap must go through several processes of wrapping and packing between the completion of manufacture and the shipping platform. During these processes the same amount of labor is now used as was used before the handling apparatus was installed. Where the non-productive labor is eliminated is in moving the material from one of these operations to another. Instead of employing men to do this, the mechanical equipment effects the transfer and the labor of these men is dispensed with.

Eliminating Non-Productive Labor in a Brickyard

This same mechanical movement between operations is clearly illustrated in the ideal handling system for a brickyard described in Article V. Here, by the usual process, brick is man-handled from the kiln to the sorting department, from this department to storage, and from storage to the carrier in which it is to be shipped. In the ideal layout, conveyors dispense with all the wheelbarrow men at present used to accomplish this movement.

*Previous articles in this series have appeared in *Chem. & Met.* as follows: Article I, vol. 26, No. 18, p. 823, May 3, 1922; Article II vol. 26, No. 19, p. 885, May 10, 1922; Article III, vol. 26, No. 24, p. 1,114, June 14, 1922; Article IV, vol. 27, No. 5, p. 199, Aug. 2, 1922; Article V, vol. 27, No. 15, p. 731, Oct. 11, 1922; Article VI, vol. 27, No. 16, p. 779, Oct. 18, 1922.

Whether the handling is manual or mechanical, about the same number of workers is employed to unload the kiln, to sort the brick, to tend the storage and to load the carriers. The elimination of the men that handle the brick between the above-mentioned workers is the means of lessening the non-productive labor and reaching a lowered cost.

In studying flowsheets for finished products, seeking means of reducing costs, the points to watch, then, are the spaces which occur between the various operations which the finished product goes through. As shown by the study of existing installations, the conveyors employed cover the movement over these spaces. A similarity in size, shape, weight and physical condition of the product handled by these systems points the way from an existing installation to the establishment of a new system.

Automatic Machinery Eliminates Much Non-Productive Labor

Many plants are found where such operations as cutting, filling, wrapping and packing are still entirely hand operations. In a large number of such cases no machinery has yet been developed to accomplish these operations. Often the machinery successfully used in one industry can, however, be adapted to another industry.

That the use of these automatic machines pays well in decreasing non-productive labor is well brought out by the example cited in Article VI. Here it is shown how the same number of workers produced twenty-five times the amount of packaged sugar when using automatic filling machines than they formerly produced when filling these packages by hand. This decrease in filling cost may seem remarkable, but it is not at all unusual. Results at least equal to this have been accomplished by many other types of filling equipment.

When wrapping machinery is considered, we find results that produce an economy well up to this level. As a general rule, it can be stated that one man operating an automatic machine will replace from ten to twenty-five workers doing the same operation by hand methods.

Studying Flowsheets to Reduce Non-Productive Labor

When studying flowsheets to find the amount of non-productive labor employed, and to determine how much can be eliminated, note two things: First, whether movement between machines is all by conveyor or not, and whether these conveyors are of the most automatic type which can be used. Second, whether the operations which the finished product undergoes are done by automatic machines or not.

If the system is not as automatic as it could be, obtain the flowsheet for another and somewhat similar industry where the maximum economy seems to be attained. This will serve as a good indication of what can be expected from a completely automatic handling system in the industry which is being studied.

What Speed of Handling Accomplishes

A speedy handling system can accomplish several direct benefits for an industry. Without exception, greater speed of handling is obtained from mechanical equipment than could ever be reached by hand methods.

The advantages following attainment of speed are:

1. A clearer idea can be reached of the rate at which the manufacturing can be scheduled and hence it becomes easier to plan the sales policy.
2. There is a much lessened possibility of any department becoming clogged with goods in process or with finished products.
3. The inventory of goods in process or completed can be kept at a lower figure, which lessens the amount of capital necessary to run the business.
4. The space required for storage throughout the plant is reduced.
5. The foremanship and inspection cost per unit of production is less—due to more product per employee and the greater capacity of oversight by inspectors.

Handling Speed and the Flowsheet

The speed of handling does not directly show up on the flowsheet which is drawn from an existing system. It is a simple matter, however, to obtain this from knowledge of the total amount of product, the speed of various machines and conveyors and similar data. Comparative figures of speed in hand-operated plants are generally easy to obtain.

No figures on this subject have been brought out in the plants described in the series because of these facts. Such figures can be obtained as desired and the speed at which a new system is to operate should be so chosen as to accommodate best the manufacturing and sales department. Note that it is always possible to attain, in handling finished products, any speeds which these departments may indicate as desirable, and this with the use of existing equipment.

The Finished Product and Management

Among the things which management must accomplish in handling finished products are the following:

1. It must keep control of the product as it passes through the plant.
2. It must effect this passage through the plant at the least possible cost.
3. It must ascertain this cost so that the business may be conducted in an intelligent manner.

Material Handling Equipment Helps Management Control the Product

By the elimination to a large extent of the human factor in handling the finished product, the management is enabled to determine far more accurately the amount of this product which may be handled. This aids distinctly in determining the amount of the product which must be manufactured and the amount of the product which must be sold. It is obviously necessary that the management must know how much of the product to make, how much it can handle as finished product and how much it can sell, in order that the business may be conducted in an economical way. Anything that helps them determine these facts tends to make the operation of an industry more economical The problems which constantly confront management of adjusting manufacturing to the market are much more easily solved when the human factor enters as little as may be into their considerations.

Control over the finished product as it passes through the plant must be maintained through the use of foremen and clerks. The amount of work necessary from these workers is almost directly proportional to the number of stops which the product makes, and is also influenced by the complication of the path of the product. By the use of automatic equipment and handling

machinery all stops except at storage points may be eliminated and the path may be practically a straight line.

Cost Accounting and Material-Handling Installations

The price at which a product may be sold will be a function of the cost of producing that product. This cost involves the cost of all the various processes which enter into the complete production of the article. It is the function of the cost accountant to determine these costs so that the management is enabled to act intelligently.

Power costs of a finished-product handling system are easily obtained by power input figures. The amount of labor is small and can easily be kept track of. Such items as upkeep and maintenance do not present difficulties to the cost department. The records which must be kept are simplified by the use of mechanical equipment and the burden on this department of the management is much reduced.

Some Points Brought Out on Lessened Management Burden

In the second article of the series the point is made that in handling many food products the principal care of the management must be in maintaining sanitary conditions. Here we see the burden of management lessened by the application of this equipment, for the reason that its use eliminates the possibility of contact with human hands or other contaminating influences.

The fourth article presents an even clearer illustration of this. Here, by the complete use of automatic methods, all manual handling is eliminated. This makes the workers merely machine tenders and does away with by far the greater part of the cost for foremanship. By the use of the automatic equipment and the elimination of labor which follows, the problem of cost keeping is reduced to its simplest terms.

The Flowsheet and Management

After the flowsheet for the finished product has been studied and a determination has been made from it of the amount of labor which can be eliminated and of the path of flow and the speed with which the products flow along this path, this sheet may be studied with a view to determining the effect of the handling system on the management. This sheet will show the operations through which the finished products must go. It will show the number of men whose services will be involved in handling the product. It will show the points at which the products stop and any points where delay or confusion might occur.

Observing these facts, it then becomes possible to determine just what the effect of any particular system will be on the management. The amount of controlling effort necessary to guide production in accordance with the management's desires will be evident, as it is proportional to the points brought out in the preceding paragraph. The cost of moving the products can be predicted with fair accuracy and the relative difficulty with which these figures are obtained under different systems will be readily seen.

How to Proceed After the Study of the Flowsheet Has Been Made

In determining the advantages to be derived from the installation of handling equipment for finished products by the study of the flowsheets of existing installations, the procedure which the writer has found to be the most advisable is as follows: Study the flow of material in several plants which are analogous to the plant in which it is desired to make a new installation. From this study determine just what the available equipment can do for you. After this determination is made, you will have certain facts in hand.

These facts will give the number of men which must be used to handle a certain product in a definite quantity by mechanical methods. They will show the path which the product must follow and will give a clear idea of the number of stops which the product must make on this path. A fairly clear idea will also be obtained of the economy effected by the use of the equipment.

With these facts in hand, we have the story of what has been accomplished by others through the use of the equipment. Lay out then a new flowsheet for the industry to which it is desired to apply the automatic and mechanical handling equipment, indicating the path which the product must take; the stops it will make and why these stops are made, naming the automatic machines and giving data on them if any are used; and giving the amount of product to be moved in a given time.

Judging a Handling System

Without indicating on this flowsheet the economies which are expected to result from the use of the equipment, it should then be submitted either to consulting engineers who make a specialty of handling layouts, or to the conveyor engineers who are in the employ of the conveyor-manufacturing companies. Supply these engineers also with such plans as are necessary to give them a clear idea of the physical conditions which will surround the handling equipment. Request them from this information to lay out an installation and to indicate on their layout the number of men and the amount of power necessary to handle the required volume of products with their system.

By comparison of the layouts submitted under this scheme with the predicted economies as shown on the flowsheets drawn for the industry and the actual economies obtained and shown on the flowsheet for similar industries, the plant which desires to install a mechanical handling system for its finished product is enabled to judge with a sufficient degree of accuracy just what benefit it will derive from installing any recommended handling system.

Dolomite for Refractories

If the lime in dolomite can be combined so as to render it non-slaking and at the same time hold up the refractoriness of the material, the abundant deposits of dolomite in the country would be rendered available for extensive use as a basic refractory, according to the United States Bureau of Mines. Briquets containing 90 per cent dolomite and varying percentages of iron oxide and clay have been burned by the Bureau of Mines at the ceramic experiment station, Columbus, Ohio. Slaking time tests were run and the results plotted on a triaxial diagram. The slowest slaking mixture was selected for making into bricks which were burned to a high enough temperature to render the lime inactive. Bricks with a high fusion temperature and high specific gravity, great mechanical strength and low porosity were the result. The work is being continued, using varying percentages of dolomite to determine the non-slaking areas over the entire field.

Refining of Salt Crude Glycerine

The Open and Closed Distillation Systems for Dynamite Glycerine —Manufacture of Chemically Pure and Yellow Distilled Grades— Operating Control and Procedure—Bleaching—Foots Treatment

By Walter E. Sanger
Wurster & Sanger, Chemical Engineers

THE refining of glycerine consists of the distillation of crude glycerine, together with subsequent bleaching to obtain a desired color. Dynamite grade of glycerine is usually obtained in one distillation whereas chemically pure (c.p.) glycerine requires a second distillation and, in exceptional cases, a treatment of the once-distilled stock before this second distillation.

Salt crude glycerine or glycerine obtained from spent soap lyes consists of glycerol, salt, water, fatty acids, esters and other impurities, and is sold on the basis of 80 per cent glycerol content[1]. Before distillation, the crude is tested for alkalinity and sufficient caustic soda is added, if necessary, to combine with the fatty acids present in the crude in order to prevent frothing as well as excessive fatty acids in the distilled glycerine. The amount of caustic required is determined for each charge of crude—there being added an excess of caustic soda sufficient to have from 0.1 to 0.3 per cent of free caustic on a boiling test.

The Two Systems of Distillation

At the present time there are in general use two systems of distillation for dynamite glycerine, which may conveniently be called the open system and the closed system. The open system is one in which the glycerine and sweet water are removed from the distillation unit in order to concentrate to the desired glycerine content. The dilute glycerine (75-90 per cent) is concentrated separately to the dynamite grade, and the sweet water is concentrated separately to make a sweet water crude glycerine which may again be distilled for dynamite glycerine or may be concentrated, bleached and sold as "yellow distilled" glycerine. In the closed system, the dilute glycerine is concentrated directly in a concentrator which is an integral part of the distillation unit; the sweet water is concentrated in the sweet water evaporator (which also is an integral part of the distillation unit) to sweet water crude, or it may be concentrated in a separate evaporator.

In the necessary distillation for c.p. glycerine both systems are the same in that it is necessary to handle the sweet water separately. In the open system the dilute c.p. glycerine is concentrated in a separate concentrator, while in the closed system it is concentrated in the concentrator, which is an integral part of the distillation unit.

It is important that the pressure on the coils of the system be in excess of 140 lb. As the pressure decreases below 140 lb. the rate of distillation falls very rapidly. A high vacuum on the system tends to produce a markedly higher rate of distillation and also an improved product. There are now on the market vacuum pumps suitable for glycerine distillation work which will pull a vacuum on closed suction to within ¼ in. of the barometer.

The Open System

The open system is shown in outline in Fig. 1. This cut shows the use of a preheater for the steam to be injected into the crude glycerine, although this steam is quite frequently introduced directly into the charge in the still. Where the latter procedure is followed, steam for injection is taken directly from the high-pressure line.

The preheater and still shells are of similar construction—namely, a steel vessel. Inside of the shells is a closed coil extending from the bottom to the top of the straight side, this coil also covering the bottom. These coils are of extra heavy pipe construction to withstand a pressure in excess of 150 lb. These coils are usually connected to steam traps so that full pressure is automatically carried on the coils. The still is further equipped with a steam injection pipe which is in the form of a perforated coil or cross on the bottom of the still. The preheater is equipped with a steam inlet pipe and also a steam outlet pipe which connects with the injection pipe in the still.

The Distilling Operation

In starting operations in the plant vacuum is first pulled on the whole unit. The still is charged with crude glycerine drawn in by vacuum or by gravity to a level of about 10 in. on the straight side of the still or about 4 in. in the gage glass. When the vacuum reaches 25 in., steam is turned on the closed coil slowly until the valve is wide open. It should require about 10 minutes to open the valve completely. The closed steam is turned on for the purpose of driving off the water in the crude as well as any water remaining in the still from a previous washing.

After the valve on the closed steam line is wide open, a small amount of open steam is turned into the preheater, where it is superheated by means of the closed coil. From the preheater this open steam is drawn by vacuum into the still through the perforated pipe, which is below the level of the crude in the still. The amount of open steam to be injected will depend on the grade of crude glycerine to be distilled; this amount will usually vary from 1 to 3 lb. of steam per pound of glycerine distilled.

As distillation proceeds, more crude is fed to the still continuously in order to maintain an approximately constant level in the still. This operation is continued until the full charge for the run has been fed. The amount of crude glycerine to be fed before running down to foots will depend on the capacity of the equipment and its design. A still run may vary from 8 to 24 or more hours.

[1]Lack of space precludes the publication here of technical specifications, methods of analysis, etc., for either dynamite or c.o. glycerine. For the former the reader is referred to British Standard Specifications for Dynamite Glycerine; the latter is described in the Pharmacopœa of the United States of America, Ninth Decennial Revision (Official from Sept. 1, 1916). For a description of salt crude glycerine see "Recovery of Glycerine From Spent Soap Lyes," by Walter E. Sanger, *Chem. & Met. Eng.*, vol. 26, No. 26, pp. 1211-16, June 28, 1922.

After the full charge of crude has been fed to the still, the feed is shut off and the operation (excepting feeding crude) is continued until the foots have the desired consistency. It usually requires from 2 to 4 hours to run the foots down to "dryness" after the last of the crude glycerine has been fed.

The vapors from the still pass to a catch-all or separator, where entrained crude is separated from the vapors and is returned to the still. The catch-all has one vapor inlet and two vapor outlets, one going to each set of air-cooled condensers.

Air-Cooled Condensers

Two sets of air-cooled condensers are usually employed. These are equipped with suitable baffle plates to cause the vapors to come in contact with the outer shells. The condensers are made of light steel plate. They are usually so connected that the condensate in each pair of condensers may be tested separately and if the glycerine is of inferior quality it may be kept separate from the satisfactory distillate and so not contaminate it. There are usually four sets of air-cooled condensers to a still, or eight condensers in all. The glycerine condensed here may be run by gravity to a closed receiving tank, whence it is transferred to a storage tank previous to being concentrated to the dynamite grade in a separate concentrator.

The glycerine condensed in the first pair of air-cooled condensers is usually tested for NaCl. If it shows none of this salt, the glycerine condensed in all of the air-cooled condensers is run by gravity into the closed glycerine receiver, which is under vacuum. If the sample shows the presence of NaCl, the air-cooled condensers remain shut off from the closed receiver and all glycerine is held in the condensers. At the end of the run these condensers are sampled by pairs and all glycerine giving a test for NaCl is run to the open glycerine receiver, whence it is usually returned for redistillation. If the NaCl content is sufficiently low, this once-distilled stock may be used for making the chemically pure grade.

The amount of distilled glycerine which is condensed in these air-cooled condensers varies considerably with the temperature of the glycerine room and is not regularly controlled by artificial refrigeration or other means. An average figure of the glycerine condensed here would be about 75 per cent of the glycerol in the original crude.

Sweet Water Condensers

The vapors which pass the air-cooled condensers go to the sweet water condensers, which are of a water-cooled surface type. Here the last of the distillate vapors are condensed to form sweet water, which is run by gravity to a closed sweet water receiver. From this receiver it is pumped to sweet water storage tanks. The amount of glycerine in the sweet water will vary considerably, but allowing 5 per cent for glycerol in the foots, this amount will be about 20 per cent of the glycerine in the original crude glycerine.

The sweet water is drawn from the storage tanks into evaporators, where it is concentrated to sweet water crude glycerine, which is again distilled to make the dynamite grade, the residue being foots, or it may be concentrated and bleached to be sold as "yellow distilled glycerine."

The handling of yellow distilled (Y.D.) glycerine and the bleaching of the dynamite grade will be discussed later under these heads.

Handling Foots and Washes

The vapor line between the still and the catch-all is equipped with a gate valve. This valve serves the double purpose of preventing any foots from splashing beyond the catch-all when washing out the still and also permits vacuum to be pulled on the rest of the unit while washing out.

At the end of a run this valve is closed and vacuum is broken on the unit. The sweet water and dilute glycerine are transferred from the unit in accordance with the use to which they are to be put. The valve on the bottom of the still is opened so that any liquid foots may be dropped into the foots tank. The foots tank has in it about 3 or 4 in. of water or washings from a previous run, which serves to prevent the foots as dropped from the still sticking to the tank bottom.

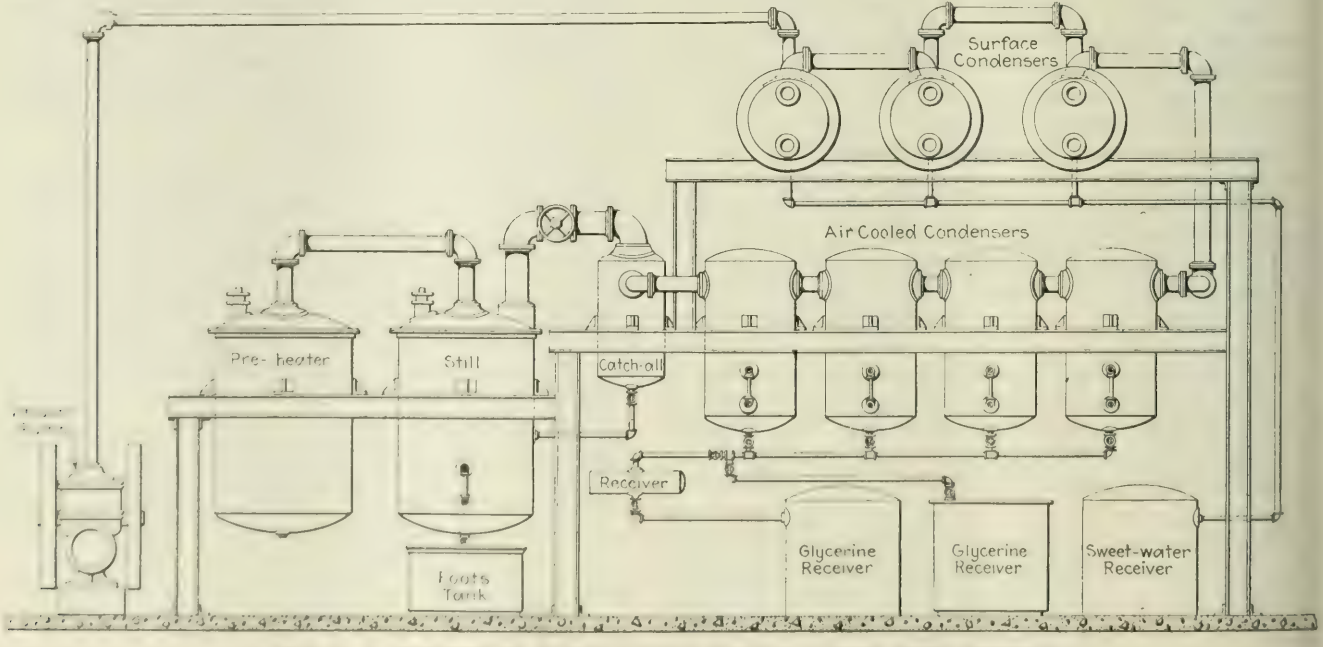

FIG. 1—A GLYCERINE DISTILLATION UNIT FOR THE OPEN SYSTEM

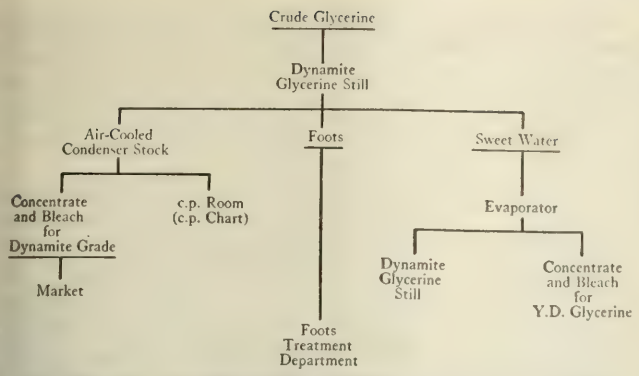


FLOW CHART FOR THE DISTILLATION OF CRUDE GLYCERINE TO DYNAMITE AND YELLOW DISTILLED GRADES BY THE OPEN SYSTEM

After all liquid foots has been dropped, the valve on the bottom of the still is closed.

The still is equipped with a nipple and valve which may be used as a vacuum breaker or as a vent line for the steam generated when washing out the still. This line is opened and water is slowly run into the still. The still coil has a temperature in the neighborhood of 350 deg. F., so that the first of the wash water is quickly converted into steam. If water is run in too rapidly, this steam may have enough pressure to strain the joints of the still, thus causing leaks.

Water is fed to the still to a level about 4 in. in the gage glass. This water is boiled for a few minutes and dropped into the foots tank. The still is usually given a second wash and, if necessary, further washes. It is usually determined by analysis how much of the wash water should be saved if the foots is to be treated for glycerine recovery. It will be understood that washes may be so low in glycerine content that it would not pay to handle them for glycerine. The washes which are to be saved are run to the foots treatment department; the other washes are run to the sewer.

The treatment of glycerine foots for glycerine recovery will be discussed in more detail under that head.

Chemically Pure Glycerine (Open System)

Where large quantities of chemically pure glycerine are manufactured, there are used separate distillation plants for the production of the dynamite and c.p. grades. Where only a small amount is produced, it is customary to use the same distillation unit for the production of both grades. In the latter case it is customary to accumulate a considerable quantity of the dynamite grade, which is later distilled to c.p. The reason for this is that the first of the c.p. glycerine distilled in a still used for dynamite has to be rejected due to the contamination of dynamite grade which deposits on the walls of the condensers.

The glycerine obtained in the air-cooled condensers from the distillation of soap lye crude will analyze about 75 to 90 per cent of glycerol. Depending on the quality of this distillate, it may be distilled for c.p. without further treatment, it may require bleaching or it may require acid and alkali treatment before the second distillation. When it is in proper condition for the second distillation, it is transferred to the still feed tank, where sufficient caustic soda is added to make it test slightly alkaline before being fed to the c.p. still.

The procedure in the distillation for c.p. glycerine is the same as that outlined for the dynamite grade. The products obtained are c.p. glycerine foots, which are returned to the salt crude still to be distilled for the dynamite grade; c.p. sweet water, which is concentrated in an evaporator to c.p. sweet water crude, which is again distilled for c.p. glycerine (the residue remaining in the still becoming c.p. foots, to be returned to the dynamite glycerine plant), and air-cooled condenser stock. This stock is concentrated in a separate concentrator and run to the first bleaching tanks, where it is diluted with distilled water to give a 95 per cent glycerine.

The Closed System

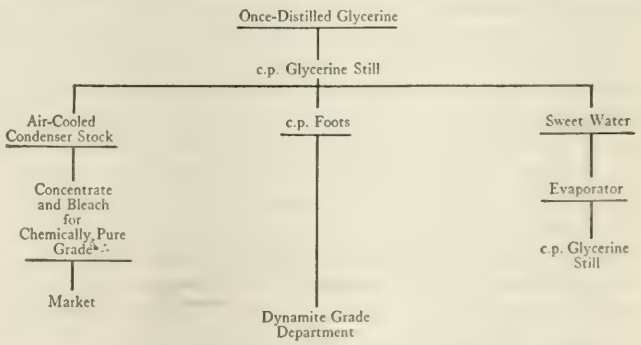
A glycerine distillation unit of the closed system type is shown in Fig. 2.

When starting the plant in operation, vacuum is first pulled on the whole unit. The still is charged with crude glycerine drawn in by vacuum to a level of about 10 in. on the straight side of the still or about 4 in. in the gage glass. When the vacuum reaches about 25 in., steam is turned on an extra heavy closed steam coil. This coil covers the bottom of the still and extends up the side close to the top of the still to prevent the condensation of vapors in the still. The valve on this steam line should be opened slowly to prevent any of the charge in the still from priming over. It should require about 10 minutes to open this valve full so that there is a pressure of 140 lb. or more on this coil. The condensation drain of the coil is connected to a trap so that full pressure may be maintained without loss of steam.

The sweet water evaporator is filled with water to a height of about 24 in. on the straight side. This evaporator is supplied with a heating coil for generating the steam to be injected into the still. A separate steam line may be run to the coil inlet, or else the drain from the still coil may be bypassed to connect to the evaporator coil inlet. The drain from the evaporator coil may be run to a trap.

After the vacuum on the still reaches about 25 in., steam is slowly turned onto the evaporator coil. The sweet water evaporator and the still are under practically the same vacuum when starting. As steam is generated in the evaporator, the vacuum on the evaporator drops; this steam is then drawn by the higher vacuum on the still into the still. The steam vapors pass from the evaporator through the preheater (which is designed as a surface condenser) and through a perforated pipe in the bottom of the still below the level of the crude glycerine.

The crude glycerine in the still has been heated to a temperature of about 350 deg. F. At this temperature the mixture of water vapors and glycerine is distilled



FLOW CHART FOR THE DISTILLATION OF ONCE-DISTILLED GLYCERINE TO CHEMICALLY PURE GRADE BY THE OPEN SYSTEM

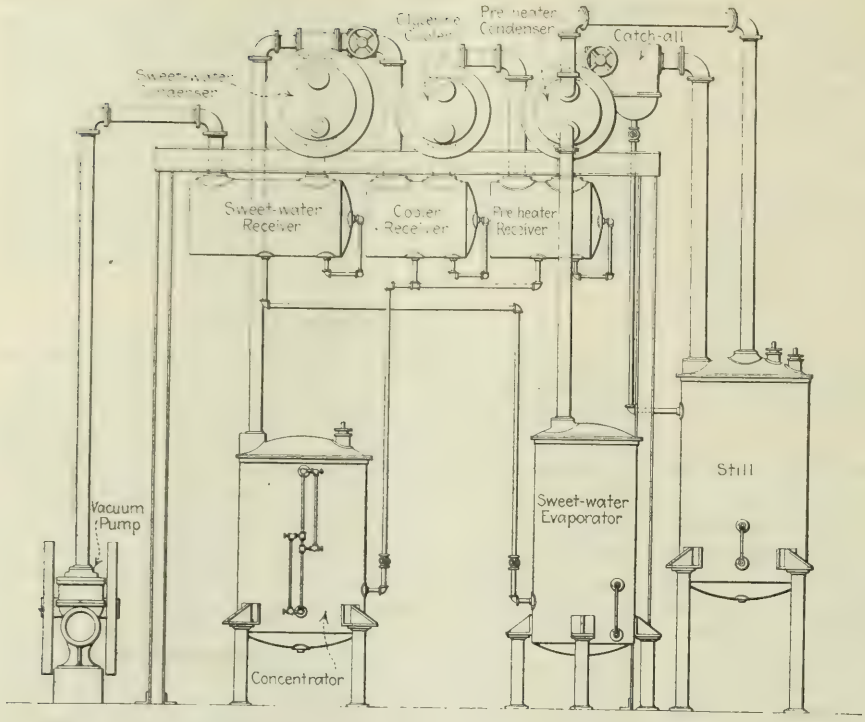


FIG. 2—A GLYCERINE DISTILLATION UNIT FOR THE CLOSED SYSTEM

off. The vapors pass from the still through a suitable catch-all, where entrained particles of crude glycerine are separated from the vapors and are returned to the still.

Condensing the Vapors

From the catch-all the vapors pass through the preheater, where they pass around the tubes, while the vapors from the sweet water evaporator pass through the tubes. The water vapors generated in the evaporator are in the form of steam under vacuum and so have a temperature of less than 212 deg. F. The mixture of water and glycerine vapors as they pass from the still have a temperature of about 325 deg. F. The vapors from the evaporator are thus preheated by the vapors from the still and are thus superheated before entering the still. The vapors from the still give up some of their heat in superheating the vapors from the evaporator and are thus condensed.

The glycerine vapors and the condensed glycerine pass from the preheater to the preheater receiver, where the vapors and glycerine are separated. The glycerine drops to the bottom of the receiver and runs by gravity to the glycerine concentrator, which is under vacuum. The vapors pass from the preheater receiver to the glycerine cooler.

The glycerine cooler is designed as a surface condenser, vapors passing around the tubes and water passing through the tubes for condensing purposes. The amount and temperature of water supplied to this cooler determines the amount of glycerine which will be condensed at this point. It is possible to condense all of the glycerine in the cooler, but if this were done, the glycerine probably would not concentrate to a sufficiently high gravity for the dynamite grade due to the presence of fatty acids, esters and glycols which are present in the distillate. For this reason, the water from the cooler is run at such a temperature that most of these impurities will pass beyond the cooler and be condensed with the sweet water.

The condensed glycerine, together with the remaining glycerine vapors, passes to the cooler receiver, where the glycerine drops to the bottom of this receiver and runs by gravity to the concentrator. The vapors pass on to the sweet water condenser.

One of the chief advantages of the closed system of glycerine distillation is the fact that the amount of glycerine to be condensed ready for concentration is easily controlled. In regular practice from 90 to 95 per cent of the glycerine in the original crude glycerine can be recovered in the form of dynamite grade.

The sweet water condenser is a surface condenser wherein the vapors pass around the tubes and water passes through the tubes. All of the condensible vapors are here condensed to sweet water. The sweet water and non-condensible vapors pass into the sweet water receiver, where the sweet water drops to the bottom and runs by gravity to the sweet water evaporator, while the non-condensible gases pass off into the vacuum pump.

As distillation proceeds, more crude glycerine is fed to the still in order to maintain a practically constant level. The cycle of operation is continued until a sufficient amount of crude for a run has been fed to the still.

The amount of sweet water obtained during a run is the sum of the water used in starting operations, the water present in the original crude and the glycerine, fatty acids, esters and glycols which are condensed in the sweet water condenser. The amount of glycerine present in sweet water usually varies from 1 to 2 per cent of the glycerine fed to the still in the form of crude glycerine.

The concentrator is equipped with an extra heavy pipe coil which covers the bottom and passes part way up the straight side of this vessel. After the glycerine shows in the gage glass on the concentrator, high-pressure steam is turned on the coil slowly so that the dilute glycerine will concentrate to the dynamite grade while the process of distillation proceeds.

After a run has been completed, the concentrator, sweet water condenser and receiver are cut off from the remainder of the distillation unit by means of a valve and the vacuum pump pulls vacuum on this part of the unit only. The vapors from the concentrator pass to the sweet water condenser. The condensible vapors are collected in the sweet water receiver, while the non-condensible vapors pass to the vacuum pump. When the charge in the concentrator reaches a temperature in excess of 350 deg. F. under a vacuum within 1 in. of the barometer, it should be of dynamite grade. It is then transferred to the bleaching department, where a sample is taken and tested. If it is of dynamite grade, it is then bleached and drummed ready for the market. An average sample of each shipment of glycerine is analyzed before shipment.

When the charge in the concentrator is finished, the vacuum is broken and the charge transferred as above described. The concentrator is not regularly washed with water.

If the stock used for making the crude glycerine was of a low quality, if the lyes had been stored for a considerable time in unclean storage tanks or if for any other reason there is present any appreciable amount of glycols, it is impossible to obtain a glycerine of the gravity required for the dynamite grade. If glycols are present, it is necessary to handle the concentrator stock for their removal, as described later.

If it is desired to concentrate the sweet water to sweet water crude glycerine or to yellow distilled glycerine in the sweet water evaporator, this is done while running down to foots. The return line from the sweet water receiver to the evaporator is closed so that sweet water will accumulate in the sweet water receiver. After the sweet water in the evaporator has been concentrated, it may be redistilled for the dynamite grade or transferred to a suitable tank, where it is bleached and handled as described under "yellow distilled glycerine."

At the end of a run the vacuum breaker on the sweet water evaporator is opened so that vacuum on the still is broken through the perforated pipe on the bottom of the still. If the vacuum on the still is broken first, the foots may be drawn through the preheater into the sweet water evaporator. Any foots in the preheater would then be washed down by the glycerine condensed here during the following run and so contaminate it that a second distillation would be required to produce the dynamite grade.

The valve on the vapor line beyond the catch-all is closed so that no foots will splash into the preheater. The vacuum breaker on the still is next opened; the foots is dropped and the still washed as described under the preceding discussion of the open system.

Bleaching of Dynamite Glycerine

The dynamite glycerine as it comes from the concentrator has a color depending on the quality of the crude from which it was distilled as well as on the design of the distillation unit.

A bleaching medium such as bone black is usually employed. This is used for the double purpose of removing coloring matter and also to give a press cake so that fine particles of solid impurities will not pass through the press cloths.

The glycerine from the concentrator is transferred to a bleaching tank, which is equipped with an extra heavy closed steam coil for heating purposes and an open air coil for agitation. For each 1,000 lb. of dynamite glycerine there is usually added 1 lb. of bleaching material, after which the charge is agitated for a few minutes with air. Where c.p. glycerine is manufactured, it is customary to use the spent bleach from the c.p. department for bleaching.

After the bleach has been added and agitated for a few minutes, the circulating pump is started. This pump takes the glycerine with bleach from the bleaching tank and delivers it to the filter press, from where it is drained back into the bleaching tank. The air is then shut off and, when necessary, steam is turned on the closed coil to maintain a temperature slightly less than 170 deg. F. If the glycerine is permitted to become cool, it is difficult to filter, and if the temperature is permitted to exceed 170 deg. F., there is danger of precipitating coloring matter. The time required for bleaching may vary from 1 hour to a number of hours. If it does not bleach readily, more bleach is added from time to time.

The procedure of circulating the glycerine through the press is continued until the glycerine is satisfactory as to color and has a "shine," which is due to the removal of all solid impurities, including the bleach. When the charge is in satisfactory condition, it is drained from the press into the drumming tank, from where it is drawn off into suitable receptacles for shipment.

Bleaching of Chemically Pure Glycerine

The glycerine from the c.p. concentrator should be very light in color. The bleaching medium may be the same as that used for the dynamite grade, although a lower quality may be used for dynamite due to the less stringent specifications regarding the percentage of ash in an incinerated sample.

The glycerine from the c.p. concentrator is transferred to a bleaching tank which is equipped with an extra heavy closed steam coil for heating purposes and an open coil for air agitation. For each 1,000 lb. of glycerine in the tank there is added 1 lb. of bleach; it is well agitated for a few minutes and then filtered through a c.p. glycerine press. The filtrate is returned to the bleaching tank and the glycerine thus circulated through the press.

Samples are taken at frequent intervals, and if the bleaching is not proceeding satisfactorily, more bleach is added from time to time. If the temperature of the stock falls below 160 deg. F., steam is turned on the closed coil to maintain a temperature slightly less than 170 deg. F.

The glycerine as it comes from the concentrator has a glycerol content in excess of 95 per cent. Distilled water to reduce the content to this figure is usually added during bleaching so as to insure thorough mixture of the glycerine and water.

The operation of circulating the charge through the press is continued until the charge meets the specifications for c.p. glycerine. It is then run to drumming tanks, from where it is drawn off into suitable receptacles for shipment.

At times it happens that even under correct temperature and vacuum conditions it is impossible to concentrate to the gravity specified for the dynamite grade of glycerine. This is almost invariably due to the presence of glycols or, more especially, to the presence of trimethylene glycol, which is a fermentation product. There are two chief sources of glycol, one being low-grade stock and the other being the fermentation of spent soap lyes.

If glycol is present in the concentrated glycerine to an objectionable extent, it may be removed by distilling off a small fraction of the glycerine in the concentrator with high-pressure steam under highest vacuum. The glycol will distill more readily than glycerine, but carries glycerine off with it. By continued fractionation it is possible to produce a distillate which is high in glycol and low in glycerine.

Yellow Distilled Glycerine

Yellow distilled glycerine is a distilled glycerine which is of lower specific gravity than the dynamite grade. It is usually made by concentrating the sweet water obtained in the distillation of crude glycerine for the production of the dynamite grade, but may be made by dilution of dynamite grade to a grade of a lower specific gravity.

There are no standard specifications for Y.D. glyc-

erine such as are recognized for the dynamite and chemically pure grades, but it is sold on sample. It usually has about the same qualities as the dynamite grade except for the gravity, which is usually about 29 deg. Bé.

If made from sweet water, it is concentrated in an evaporator to the desired specific gravity and then bleached and clarified as described under bleaching of the dynamite grade.

Treatment of Glycerine Foots From Salt Crude Glycerine

The residue left in the still at the end of a run is known as glycerine foots. This term is applied both to the residue as such and also to the mixture of residue and water which is obtained when washing out the still. The amount and quality of glycerine foots or foots obtained from any run will depend largely on the quality of the stock from which the salt crude glycerine was obtained, as well as on the efficiency of the lye treatment.

Foots consists of salt, glycerine, fatty acids, esters, polyglycerols and water. The amount of glycerine present will depend relatively on how far down the foots has been distilled. It is the practice in some factories to distill to dryness and then run the washings to the sewer; other factories drop foots in a semi-liquid state and then treat it for glycerine recovery.

The chief ingredients to be removed from the foots are the salt and fatty acids. Salt is easily removed by evaporating the solution to foots crude glycerine. However, if the fatty acids are not largely removed, this crude will distill very slowly and not much of the glycerine can be recovered. The main problem in foots treatment consists in the elimination of fatty acids.

The fatty acids present are those of the acetic series. A mineral acid will displace a fatty acid upon concentration; a mineral salt will combine with a fatty acid to form an insoluble mineral soap, qualitatively speaking. These conditions are usually made use of in the treatment of foots regardless of what varieties of treatment are given.

Outline of a Complete Method of Treatment

The following is an outline of a complete method of foots treatment which may be varied to meet special conditions in any given plant:

The foots as washed from the still is treated with a small amount of soda ash and then filtered through a press. This treatment precipitates some of the fatty acids as sodium soap, but is primarily used to clarify the foots by removing flocculent material which is present.

The solution is run from the filter press into lead lined tanks, where 60 deg. sulphuric acid is added. The amount of acid to be added is determined in the laboratory, where three samples of foots are treated with varying amounts of 60 deg. sulphuric acid in graduated glass vessels. Upon standing for a number of hours, there is a separation of tarry matter on the top and light material on the bottom. It is observed which of the three samples shows the best separation, and this is taken as the quantity to be added to the foots in the tank. The specified amount of 60 deg. acid is added to the tank and the charge is warmed by open steam and thoroughly agitated with air. After about 24 hours the tarry matter, which contains considerable fatty acids, is skimmed off and discarded.

After the tarry matter has been removed the strongly acid foots is transferred to a wood vat, where it is treated to a strong alkalinity with milk of lime, which precipitates some of the remaining fatty acids. This mixture is filtered to remove the lime and lime soap, the filtrate being run to a tank, where soda ash is added to remove the excess of lime. This lime precipitate is removed in a press and the filtrate transferred to the spent soap lyes, to be again concentrated to salt crude gylcerine. Where high grades of stock are used, such as in toilet soap factories, the foots may be thus returned for several years.

A simple and frequently employed method of treating foots is to transfer the foots from the still to a tank where sufficient sulphate of alumina is added to precipitate all fatty acids which can thus be removed. This solution is filtered into a second tub where sufficient acid is added to neutralize the ash alkalinity of the foots. This strong acid solution is then evaporated to foots crude glycerine.

Chicago, Ill.

The German Zinc Market

A pronounced shortage of zinc exists in Germany at present, says *Commerce Reports* of Oct. 9. Visible stocks are estimated at 8,000 metric tons, as compared with 14,000 metric tons a year ago.

The numerous factories using zinc in the Rhineland, Westphalia and other industrial centers of Germany are averse to consuming their small reserves and are endeavoring to cover their current needs by purchases in the open market. This is becoming increasingly difficult, due both to the scarcity of the metal and to the phenomenal upward movement of prices.

Numerous factors are responsible for the shortage of zinc in Germany. One of the most important was the loss of 80 per cent of the former Silesian zinc production to Poland. It was thought that this loss, which occurred in June, would not be felt immediately, since a free exchange of raw materials was provided for in the agreement covering the surrender of this territory, but transportation difficulties have prevented the arrival of expected shipments of zinc from Silesia. Constantly increasing acuteness of the coal situation and mounting prices of coal also hamper production.

Limited stocks in other countries make it seem unlikely that relief will come in the near future from abroad, even if German exchange should materially improve.

Carbide and Cyanamide Industry Slack in Norway

Norway has eight modern well-equipped calcium carbide plants, three of them built during the war, with a total annual output capacity of about 265,000 tons. These plants have installed about 170,000 hp. and in full operation employ about 3,000 men. Several of them are now completely closed down, and the others are operating with small or minimum force.

Commenting on this situation in a recent address, Ove Collet, a leading Norwegian electrochemical engineer, said that before the war the total world's production of calcium carbide was about 350,000 tons per year; that today Norway has factories with a capacity of nearly 80 per cent of the pre-war world production, and that war-time optimism as to the future of carbide has proved without sound basis, especially so far as the production of cyanamides is concerned.

The single cyanamide factory in Norway, that at Odda in the Bergen district, with its annual capacity of 75,000 tons, has been closed down for more than a year, and it is extremely doubtful whether it, or the carbide factory at the same place, which counted upon delivering a large part of its product for the manufacture of cyanamides, will ever again be in operation —certainly not unless new uses for both carbide and cyanamides can be found.

Overstrain, Internal Stresses and Creep

Effects Similar to Those Caused by Working Iron at Blue Heat Have Been Observed in Nickel and Certain Alloys—These Phenomena and the Results of Overstrain Are All Due to Rapid Acquisition of Increased Strength on Slip Planes

By Zay Jeffries and R. S. Archer

When hot-rolled iron or mild steel is tested in tension, it is found that the first part of the stress-strain diagram is a straight line, representing elastic deformation up to roughly one-half the tensile strength. If a bar of such material is loaded to a stress well beyond its yield point, it will be found on removal of the load to have lost its elasticity. On a second application of the load, the stress-strain diagram curves away from the straight line representing proportional deformation; the proportional (or elastic) limit has been reduced practically to zero. If after the first loading beyond the yield point (overstraining) the bar is permitted to rest for a few weeks before the second tensile test, it will then be found to have recovered its elasticity, and may have a new proportional limit higher than the original proportional limit of the hot-rolled material.

This recovery of elasticity takes place slowly at ordinary temperatures, but more rapidly as the temperature is raised. Muir found that the recovery of elasticity at 100 deg. C. is as complete after a few minutes as in 2 weeks at room temperature. At 250 deg. C. the time required is measured in seconds or fractions.

While the proportional limit in tension can be greatly increased (approximately doubled) by overstrain in tension followed by aging or heating at low temperatures, the limit in compression is not similarly increased. In fact, it has been stated that the gain in tensile proportional limit is almost exactly compensated by loss in compressive proportional limit, so that the total elastic range is not greatly changed. Van den Broeck[1] has reported, however, that by stretching and reheating, the proportional limit of mild steel in tension can be about doubled, while still retaining approximately the original proportional limit in compression. In Fig. 1 the effects of aging and tempering are shown. Curve No. 118 shows the elastic properties of a hot-rolled low-carbon steel. Curves 114 and 171 show how the elastic limit in tension is reduced practically to zero by cold deformation either in tension or compression. The other curves illustrate the recovery of elasticity by aging and by heating to 100 deg. C. The elastic limit in tension of the steel which was compressed and heated to 100 deg. C. has not quite been restored to its original value, but it is possible it would upon further heating.

FIG. 1—EFFECT OF AGING AND TEMPERING ON THE ELASTIC PROPERTIES OF COLD-WORKED MILD STEEL. (VAN DEN BROEK)

Recovery of elasticity on aging at ordinary temperatures or on heating at temperatures up to about 300 deg. C. is accompanied by increase in hardness and tensile strength and by loss of plasticity. Elongation is usually reduced to a marked extent, although the reduction of area is less affected. The change that takes place is therefore a general hardening and stiffening.

Blue Heat Phenomena in Iron

It has long been known that iron is peculiarly brittle at temperatures from 200 to 400 deg. C., and that deformation, such as bending, effected at these temperatures causes the metal to be much more brittle after cooling to room temperature than would a similar amount of deformation at room temperature. Because of the blue scale or temper color formed on iron and steel, this temperature range is commonly called a "blue heat," and the brittleness is called "blue brittleness."

Tensile tests at elevated temperatures show that iron actually has a higher tensile strength but lower elongation and reduction of area in the blue heat range than at room temperature. The curves in Fig. 2 show the results of tests at the U. S. Bureau of Standards[2] on a mild steel whose properties are essentially those of iron. Results of a similar nature have been reported by one of the authors,[3] and are reproduced in Fig. 3. Robin has shown that the Brinell hardness is also greater at a blue heat than at room temperature.

The fact that a given amount of deformation effected at a blue heat hardens iron to a greater extent than does the same amount of deformation effected at room temperature is illustrated nicely by some experiments on the drawing of Armco iron wires. For example, wires reduced cold from 0.042 in. to 0.025 in. (64 per cent) at room temperature and at 275 deg. C., had the following tensile properties (measured at room temperature):

Temperature of Drawing	Tensile Strength Lb. Per Sq.In.	Elongation Per Cent	Reduction of Area Per Cent
Room temperature.	85,720	2.60	70.0
275 deg. C.....	111,000	1.58	67.0

The wire drawn at blue heat is stronger and less plastic than that drawn at room temperature.

About 30 years ago Le Chatelier[4] observed that the tensile properties of iron in the blue heat range are greatly affected by the rate of application of load. One specimen, for example, had a tensile strength of 66,850 lb. per sq.in. and an elongation of 10 per cent when broken in 20 minutes at a temperature of 170 deg. C.

[2]"Strength and Elasticity of Boiler Plate at Elevated Temperatures," H. J. French, *Chem. & Met. Eng.*, vol. 26, p. 1207.

[3]"Effect of Temperature, Deformation and Grain Size on the Mechanical Properties of Metals," Zay Jeffries, *Trans.*, A.I.M.E., vol. 60, p. 474.

[4]Abstracted in "The Blue Brittleness and Aging of Iron," Fettweis, *Stahl und Eisen*, Jan. 2 and Jan. 9, 1919.

On increasing the rate of pulling until fracture occurred in 2 seconds, the tensile strength fell to 38,400 lb. per sq.in., while the elongation rose to 28 per cent. The general result of his researches follows:

With various rates of applying load, the curves which give the tensile properties of iron as functions of temperature are approximately the same shape, but when testing at higher speeds, the curves are shifted toward higher temperatures. In other words, the maximum in strength and hardness does not occur at a fixed temperature, but at a temperature which depends on the rate of loading and is higher as that rate increases.

To explain these phenomena, Le Chatelier postulated that at temperatures above about 80 deg. C. any permanent deformation of iron gives rise to an irreversible transformation which tends to raise the tensile strength and decrease the ductility. This transformation requires a certain amount of time for its complete development, but takes place more quickly the higher the temperature. Above 300 deg. C., however, the transformation is less effective in producing strength and hardness, because of incipient annealing.

In a paper published in January, 1919, by Fettweis,[4] this transformation of Le Chatelier is, apparently for the first time, identified with the transformation responsible for elastic recovery after overstrain. Fettweis did not propose any hypothesis as to the mechanism of this transformation.

In February, 1920, one of the present authors[5] independently stated the theory that the blue heat phenomena and elastic recovery are due to the same cause: A spontaneous increase in resistance to motion on the slip planes formed during deformation.

[5]Discussion by R. S. Archer, on paper "Physical Changes in Iron and Steel Below the Thermal Critical Range," Zay Jeffries, February, 1920, meeting A.I.M.E.

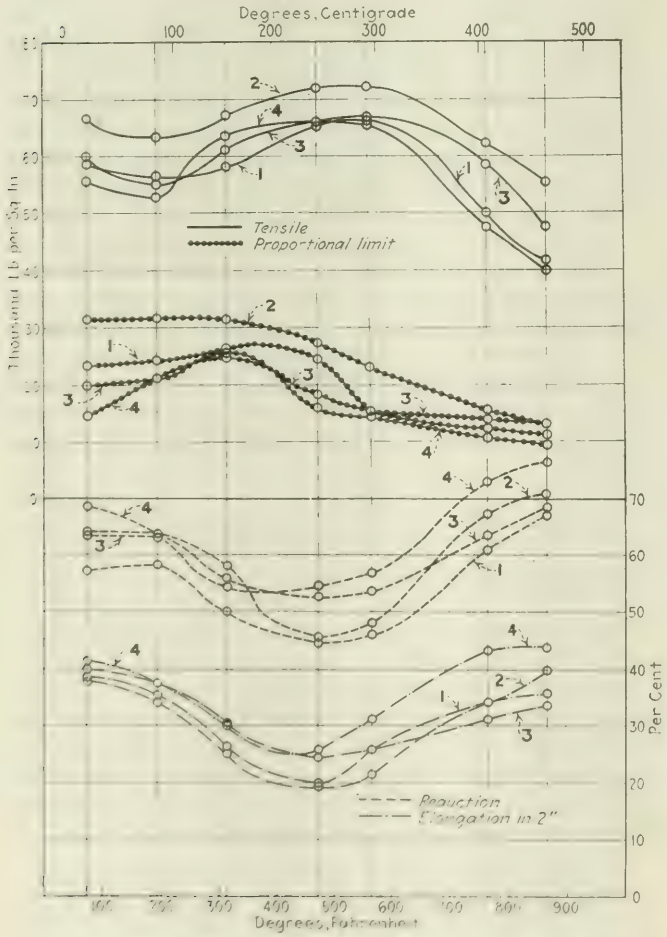

FIG. 2—EFFECT OF TEMPERATURE ON TENSILE PROPERTIES OF MILD STEEL. (FRENCH)

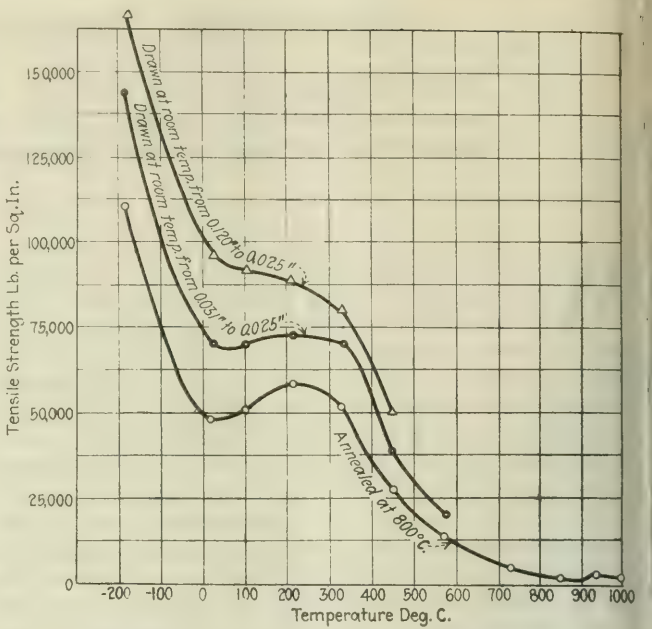

FIG. 3—TENSILE STRENGTH OF ANNEALED AND COLD-DRAWN ARMCO IRON WIRES AT VARIOUS TEMPERATURES. (JEFFRIES)

It is supposed that immediately after motion begins on a slip plane the resistance is less than the shearing strength of the unbroken crystals. Deformation tends to progress by continued motion on this plane, until brought to a halt by end resistance—that is, by the interference of adjacent grains. If the deforming load is removed immediately after slip has started and time is allowed for elastic recovery, then the resistance to motion on the plane of slip spontaneously increases to a value equal to or greater than the resistance to the formation of a new slip plane. Further deformation must then take place on new planes. The time required for this increase in resistance is less as the temperature rises, so that at about 250 to 300 deg. C. the change is practically instantaneous and occurs during the progress of any ordinary deformation such as a tensile test. The result is that at a blue heat a given *external* deformation produces more internal deformation, or cold-working, and hence more *hardening*, than the same amount of external deformation effected at room temperature.

This statement applies to deformations effected within a short period of time, such as during an ordinary tensile test. If the deformation which takes place during the tensile test at room temperature could be effected very slowly so that there was time for elastic recovery during the test, we should expect the tensile strength to be increased to an extent comparable with the increase obtained at a blue heat. The following experiments made by J. T. Bottomley[6] in Lord Kelvin's laboratory confirm this expectation:

Eight pieces of soft iron wire were tested in tension by gradually increasing stress applied in 10 minutes of time in each case. They broke at loads of 43.5 to 46 lb. (average 45.2 lb.) with 17 to 22 per cent elongation. Another specimen left with 43 lb. hanging on it for 24 hours and then broken by gradual increase of stress during 25 minutes broke at a load of 49.25 lb. with 15 per cent elongation.

[6]"The Testing of Materials of Construction," Unwin, 3rd ed., p. 113.

Another left for 3 days with 43 lb. hanging on it and then broken by increasing stress bore 51.5 lb. and elongated 14.4 per cent. A wire loaded first with 40 lb. and broken with gradual addition of load in 2 months broke at 57.25 lb. The slower loading had therefore increased the strength by about 27 per cent, which is an increase of the same order of magnitude as that obtained by testing in the blue heat range with ordinary rates of applying load.

According to the theory here described, the blue heat properties of iron are due to certain peculiarities of the process of deformation, and are not specific properties of crystalline iron. The yield point, tensile strength, Brinell hardness, elongation and reduction of area are all properties whose measurement necessarily involves plastic deformation. The true elastic limit, on the other hand, being the stress at which plastic deformation begins, cannot be affected by the mechanism described, nor can the modulus of elasticity. Unless there is an allotropic change (change in atomic arrangement), it is to be expected that both elastic limit and elastic modulus will decrease continuously as the temperature rises.

There is a lack of sustaining evidence of any allotropic change in these temperature regions, and recently E. C. Bain has found by X-ray analysis that iron at 300 deg. C. has the same body-centered cubic lattice as at room temperature.

TABLE I—STRENGTHENING OF NICKEL WIRE AT 250 TO 275 DEG. C.

Treatment of Specimens	Tensile Strength, Lb. Per Sq. In.	Per Cent Increase
Kept in liquid air until tested, 15 min. after drawing	125,000	.....
Kept in liquid air until tested, 15 min. after drawing	126,000	.....
Kept in liquid air until tested, 15 min. after drawing	126,000	.....
Kept in liquid air until tested, 15 min. after drawing	126,000	.....
Average	125,750	
Heated at 275 deg. C. 2 min	130,500	3.1
Heated at 275 deg. C. 5 min	132,000	4.6
Heated at 275 deg. C. 10 min	130,000	.....
Heated at 275 deg. C. 30 min	131,000	.....
Kept in liquid air until tested, 45 min. after drawing	126,000	.....
Heated at 250 deg. C. 1 min	128,000	1.6
Heated at 250 deg. C. 2 min	128.000	1.6
Heated at 250 deg. C. 5 min	128,000	1.6
Heated at 250 deg. C 20 min	130,000	3.2
Kept in liquid air until tested, 2 hr. after drawing	125,000	.....
Heated at 250 deg. C. 5 min	128,000	2.45
Heated at 250 deg. C. 15 min	130,500	4.00
Heated at 250 deg. C. 3 hr	127,000	.....

Actual determinations of elastic limit by various investigators are not in good agreement. Howard[7] in 1890 reported that the elastic limit decreases with rise in temperature. Huntington[8] also gave a curve which does not pass through any maximum in the blue heat range. Martens,[9] however, reported that the elastic limit passes through a maximum at about 200 deg. C., and recently H. J. French[2] found a maximum value at 200 deg. C. about 14 per cent greater than at room temperature. Accurate determination of proportional or elastic limit at the higher temperatures is a matter of some experimental difficulty, and in fact the values found in any determination depend on the sensitivity of the instruments. From the sufficiency of the deformation theory in explaining the other blue heat properties and the evidence against an allotropic change, it is very probable that the "elastic limit" which increases in the blue heat range involves some plastic deformation and that more sensitive measurements would show a continuous decrease in elastic limit and elastic modulus. The rise in tensile strength at a blue heat is most pronounced for iron in the annealed condition. Such strengthening becomes less in cold-worked irons tested at a blue heat, and finally in iron severely cold-worked and aged for some time, the tensile strength at room temperature is greater than at any higher temperature. This simply means that, because of the great hardening already obtained by cold-working and aging, the hardening effect of the relatively small deformation occurring during the tensile test is not sufficient to compensate for the natural loss of cohesion due to the rise in temperature. Furthermore, heating to temperatures as low as 100 deg. C. produces a slight softening in iron which has been severely cold-worked and aged.

Overstrain in Non-Ferrous Metals

Iron appears to be unique in the magnitude of the overstrain and blue heat phenomena, but similar properties have been observed in some other metals.

It has been found that the tensile strength vs. temperature curve for nickel exhibits a horizontal portion between 200 and 300 deg. C., although the tensile strength does not actually rise in this region. There is a corresponding drop in elongation and reduction of area. This has been attributed to the allotropic change in nickel supposed to correspond to the magnetic change at 320 deg., but recently the space lattice of nickel at 500 deg. has been determined by E. C. Bain and found to be the same as at room temperature. The magnetic change is therefore not due to allotropy (in the sense of atomic rearrangement). In view of the properties of iron, it seemed probable that the break in the tensile strength-temperature curve of nickel was due to the same sort of spontaneous hardening.

W. P. Sykes has recently made some tests which show that freshly cold-drawn nickel wires are hardened by heating at 250 and 275 deg. C. His results are given in Table I. The nickel wire was drawn cold from 0.090 in. to 0.025 in. diameter. This wire was immersed in liquid air immediately after coming through the finishing die and kept in liquid air until tested or put in an electric muffle furnace for heat-treatment as designated in the table. Immersion in liquid air was for the purpose of preventing the hardening process from taking place, as it is known that in iron the change is extremely slow at low temperatures.

Price and Davidson[10] have also reported a hardening effect on heating cold-rolled nickel at temperatures up to 450 deg. C. Brinell hardness of bars cold rolled from 0.5 in. to 0.134 in. was as follows:

As rolled	235
Heated to 250 deg. C.	262
Heated to 350 deg. C.	255
Heated to 450 deg. C.	248
Heated to 550 deg. C.	228

The heating time was ½ hour to reach temperature plus 25 minutes at heat in all cases. A maximum strengthening effect was found in longitudinal specimens after heating at 250 deg. C., the strength increasing from about 123,000 lb. per sq.in. to 134,000.

It has been reported that the first effect of annealing cold-worked copper and aluminum at low temperatures is to increase the strength or hardness, but these observations are not well established.

It is well known that the first effect of annealing cold-worked brass is a slight hardening. Bengough and Hudson, working with a 70:30 brass, found that the tensile strength increased in all cases with rise in

[10]Discussion on "Physical Properties of Nickel," by Browne and Thompson, *Trans.*, A.I.M.E., vol. 64, p. 414.

annealing temperature up to about 300 deg. C. The yield point remained practically constant up to 100 deg. or higher, after which it dropped off. The effect of rest and low-temperature annealing on the elastic limit was investigated in one case, and it was found that the elastic limit was not affected by aging for 12 days at ordinary temperatures or by heating for 1 hour at 90 deg. C. The yield point was raised by both of these treatments. Annealing 1 hour at 210 deg. C. considerably decreased both elastic limit and yield point.

Bassett and Davis,[11] in their careful work on the relation of grain size to Brinell hardness in cartridge brass, found that annealing at low temperatures increased the Brinell hardness of the cold-worked metal, the increase being more marked the greater the reduction by rolling. This is shown in Fig. 4.

The increase of tensile strength reported by Bengough and Hudson has been confirmed by Mathewson and Phillips.[12] Their material was a very pure 70:30 brass which had been reduced cold 40 per cent. In this condition the average properties (five tests) were:

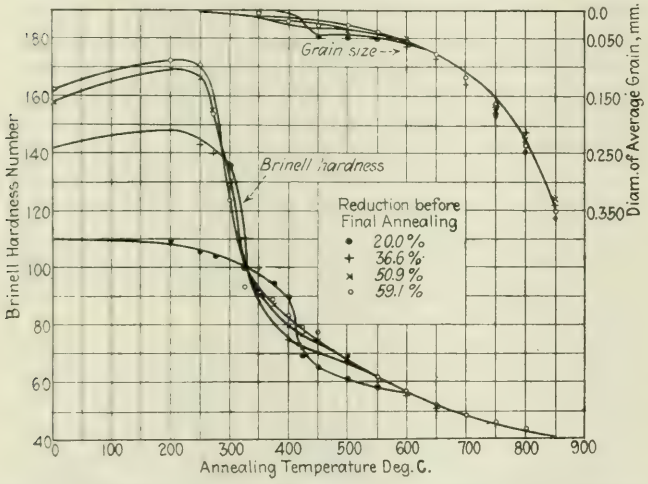

FIG. 4—EFFECT OF ANNEALING ON BRINELL HARDNESS OF COLD-WORKED BRASS. (BASSETT AND DAVIS)

tensile strength 76,763 lb. per sq.in., elongation 11.1 per cent and scleroscope hardness 33.2. After heating for ½ hour at 200 deg. C. the tensile strength (average of five tests) was 78,512, elongation 10.0 and hardness 34.2. Annealing at 300 deg. C. caused appreciable softening and visible recrystallization.

In connection with their investigation of season-cracking in brass, Moore and Beckinsale[13] have determined the effect of heating for 1 hour at temperatures from 250 to 325 deg. C. on the elastic limit. Their curves are reproduced in Fig. 5. It will be observed that the treatment at 250 deg. C. practically doubled the proportional limit. Treatments at higher temperatures have in all cases left the metal in an elastic condition, although the proportional limit decreases as the temperature of treatment is raised.

Hardening effects have been observed in nickel silver. F. C. Thompson found that the Brinell hardness was increased from 130 to 143 by annealing ½ hour at 300 deg. C. Price and Davidson[14] have also reported an

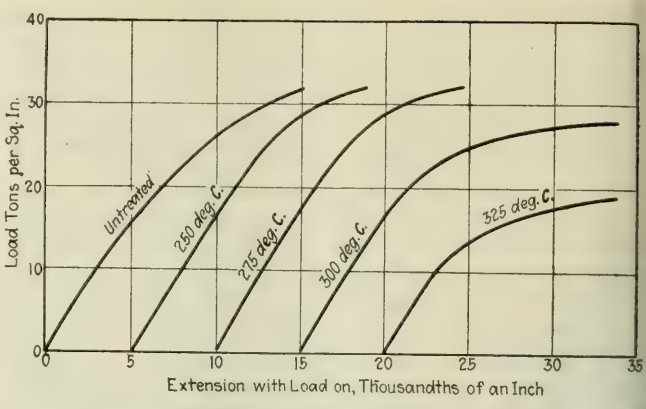

FIG. 5—EFFECT OF HEATING AT LOW TEMPERATURES ON ELASTIC PROPERTIES OF COLD-WORKED BRASS. (MOORE AND BECKINSALE)

increase in both yield point and tensile strength on annealing cold-worked nickel silver at 350 deg. C.

On the basis of the theory given above for the blue heat properties of iron it might be expected that brass and nickel silver would show discontinuities in hardness and strength when tested slightly above room temperature. Unfortunately, most of the work on the properties of these alloys at higher temperatures has not included tests between 20 and 200 deg. C.

The evidence on the occurrence of overstrain and blue heat phenomena in metals other than iron is thus rather limited. There is a strong indication that the phenomena are of general occurrence, although they are certainly most prominent in iron. It may or may not be of some significance that both iron and nickel are magnetic and that the extent to which spontaneous hardening is manifested is greater in the more magnetic element.

Internal Stresses and Creep

When a bar of iron is unloaded after being strained beyond its yield point, it does not return immediately, but approaches a stable position with increasing slowness. A more familiar example of the same phenomenon is found in the behavior of iron or steel when it is attempted to bend a piece to some desired shape, as in "straightening" a forging. It is at once apparent that in order to make the piece assume a final desired position it is necessary to bend it *past* this position, as there is an immediate elastic spring toward the original shape. Having caused the piece to assume the desired shape, it may be found some days later that it has returned still further toward its original shape. This slow return is often called "creep."

Creep is due to the action of internal stresses, produced by the deformation, slowly moving the crystalline fragments back along the slip planes toward their original positions. As has been remarked before, the elastic limit of a piece of metal is not passed until stresses are set up in some of the grains exceeding their shearing strength along the planes of easy slip. By the time the yield point is reached, practically all of the crystalline metal is highly stressed. When the load is removed, these elastic stresses are to a large extent relieved, but some remain to be gradually lessened by the slow movement of the grain fragments along the slip planes. Freshly formed slip planes have a relatively low resistance to motion. After elastic recovery is complete, little or no creep is to be expected. As a practical example, steel forgings are often

[14] "Physical Tests on Sheet Nickel Silver," Price and Davidson, *Trans.*, A.I.M.E., vol. 64, pp. 510-523.

traightened at or above a blue heat, so as to "stay put." 'he internal stresses set up by overstraining are ever completely relieved unless the metal is in a semi-lastic condition in which its elastic limit is substan-ally zero. That is, internal stresses are relieved only y flow, and their relief is opposed by elasticity. Metals nd alloys which are elastic at ordinary temperatures re left in a state of internal stress (also spoken of as internal strain") by all commercial cold-working rocesses. High internal stresses can also be produced y uneven temperature changes. Rapid cooling, uneven ections and mass contribute to such stresses.

The algebraic sum of the internal stresses in a piece f metal must always be zero; that is to say, tensile resses in one portion are balanced by compressive resses in other portions. An analogy may be drawn the various members of a steel bridge, which may ch be stressed in a different way, in tension, in com-ression, under bending, or under combinations of such resses, although the entire structure is in a state of uilibrium as regards external forces. Now if a bridge ember in tension is cut in two, its ends spring apart, d the sound members rearrange their loadings as best ey can; on the other hand, if a compression member cut, the ends come together. Internal stresses in a ece of metal can be detected and measured by means f the same principle.

If a light cut is machined from the surface of a piece f cold-drawn rod whose length has been carefully easured, a second measurement will show that the ngth of the remaining bar has increased. This means at initially the external layers of the rod were in a ate of tension while the core was in compression. On moving some of the exterior metal, which was hold-g the core in compression, the compressive stress in e core is partly released and it automatically in-eases in length a corresponding amount. The average ress intensity in the layer of metal which has been moved can be calculated from the observed change in ngth of the remainder of the rod: the relative change length times the modulus of elasticity gives the ress which has been released; this stress multiplied by e area of the section gives the total force released, hich is exactly equal to the tensile force in the metal achined off. This force divided by the cross-section ea of the metal machined off gives the average stress tensity in that metal.

The dimensional changes which result from cutting way part of an internally stressed piece of metal are ten a source of considerable trouble. A surface orig-ally machined "true" may be thrown out of true on moving stressed metal from some other portion of e piece.

If the external load to which a metal is subjected in rvice happens to be added to internal stresses already esent in the piece, the total stress may exceed the ength of the material and failure may result at an ternal load far below that which would normally cause ilure. Under some exceptional circumstances, it is ssible to utilize internal stresses to oppose external ds and thus extend the useful strength of the metal. dinarily, however, internal stresses are considered to a source of weakness.

Metals sometimes fail spontaneously from internal esses. The most common examples are hardened el and cold-worked brass. Severe stresses are set up steel by the hardening operation, both by uneven nperature changes in themselves and by the volume changes incident to hardening. Such induced stresses are often sufficient to burst the steel, either during the hardening or some time thereafter.

Removal of Internal Stress in Brass

Cold-worked articles of brass, such as cold-drawn bars, cartridge cases or spun jars or cups, often split open spontaneously. The failure may occur months or years after fabrication, and is known as "season cracking." It is due to internal stresses induced by cold-working, assisted usually by corrosive action. Season-cracking can be prevented by so controlling the deforming operations as to avoid setting up excessive internal stresses or by reducing the internal stresses to a safe value by annealing. It was shown by Merica[15] that the internal stresses in brass can be reduced below the danger point by annealing at temperatures too low to produce visible recrystallization or appreciable softening. More recently a very interesting quantitative study of the removal of stresses in brass by low-temperature annealing has been reported by Moore and Beckinsale.[13] Their results are summarized as follows:

"1. The rate of reduction of stress is fairly rapid at 200 deg. C. at first, but becomes very slow when the stress has been reduced to one-half to one-third its initial value and important stresses remain even after treatment for 24 hours or longer.

"2. As the temperature is raised the rate of reduction of stress increases, but shows the same characteristic of slowing down as the stress falls. At 300 deg. C. a very much shorter time is required to reduce the stress to a given figure than at 200 deg. C. and the remaining stress is much lower after a given time at the higher temperature, in brass of the same hardness.

"3. The higher the initial stress the higher is the remaining stress after a given treatment, in brass of the same hardness, although the amount of stress removed is greater the higher the initial stress.

"4. The higher the hardness of the brass the lower is the remaining stress after a given treatment and for a given initial stress. In other words, the harder the brass the more rapidly is a given initial stress reduced at a given temperature.

"5. A large reduction in the amount of stress is brought about by annealing conditions (temperature and time) which raise the hardness of cold-worked 70:30 brass, but treatments which result in some reduction of hardness are necessary to bring about complete removal of stress.

"6. At temperatures in the range 200 to 300 deg. C. slight plastic flow occurs in cold-worked brass at low stresses. The amount of flow is greater as the temperature is higher, the stress greater and the time longer for which the stress is maintained.

"7. The reduction of internal stress by low-temperature annealing is dependent on the plastic flow mentioned in (6).

"8. This plastic flow involves a lowering of the elastic limit at the temperature at which it occurs. This reduction of elastic limit is, however, not permanent provided the treatment is applied for a time not exceeding 1 hour at 275 deg. C. or certain limiting times which are much longer at lower temperatures. The limit of proportionality and elastic limit are raised considerably by treatments which do not exceed these limits of temperature and time."

These results are true specifically only for a 70:30 brass, but some general conclusions are warranted regarding the removal of internal stresses from other metals induced by cold-work or temperature changes. The temperatures at which stresses are removed from brass are near the lowest temperature of recrystallization. Complete removal of stress required an annealing which produced some softening and hence some recrystallization. It is probable that any metal must be heated to a temperature near its recrystallization temperature to remove stresses; heating to higher temperatures will result in more complete removal.

Manufacture of Carbon Bisulphide*

By George A. Richter
Research Department, Brown Co., Berlin, N. H.

In the past 20 years there have appeared from time to time in various technical journals articles describing in some detail the manufacture of carbon bisulphide in the electric furnace. Most of the articles in recent years have referred specifically to the so-called Taylor process. By using production data and power-consumption figures given by Mr. Taylor, others have calculated the approximate thermal efficiency of the operation. Such estimates are based upon the thermal constants to be found in the literature, and indicate a thermal efficiency ranging from 35 to 55 per cent, according to the assumptions made.

It has been thought of sufficient interest to go into the study somewhat further, with a hope of striking a thermal balance in order to approximate at least the distribution of heat losses in the manufacture of carbon bisulphide.

Inasmuch as the writer has had no personal experience with the Taylor method of making carbon bisulphide, it will be necessary to make such calculations from data obtained from a manufacturing process which differs in some essentials from the better-known Taylor process. In order to avoid a misunderstanding, it will be advisable (1) to review the general principles involved in the production of bisulphide of carbon, (2) to describe briefly, but specifically, the process under consideration, and (3) to give some data and calculations covering the process.

General Principles of Manufacture

Large-scale production of carbon bisulphide is based upon a direct union of two elementary substances, carbon and sulphur, such a union taking place from 600 to 1,000 deg. C. At these reaction temperatures the sulphur is obviously present as a vapor and the unreacted carbon exists as an incandescent solid. Care must be used in selecting the type of carbon for successful operation. In the writer's experience, gas coke, anthracite coal and other forms of dense carbon have proved of little use. Best results are possible with a reasonably good grade of willow or birch charcoal, which has a low ash content.

It is important that both sulphur and carbon employed be as dry as practicable. Water brought into the furnace as moisture in the sulphur reacts with the sulphur in the high-temperature zone, forming hydrogen sulphide and other volatile sulphur compounds. These side reactions evidently convert sulphur into useless products at the expense of some heat.

Water present in the charcoal delivered to the furnace is usually distilled from the furnace at a temperature lower than that needed for reaction with sulphur. This is due to the fact that charcoal is usually introduced into the furnace at the upper low-temperature zone in order to conserve heat by employment of countercurrent principles. This calcination of charcoal results in a certain small loss of heat, as will be discussed later. It is also of importance to specify a well-burned charcoal. A poorly burned product contains substantial amounts of hydrocarbons which cause loss of both heat and sulphur, due to the formation of useless sulphuretted compounds, which distill off with the carbon bisulphide. In practice it has been found profitable at times actually to dry and reburn some of the charcoal purchased before putting such charcoal into the furnace.

Description of Process

Fig. 1 shows diagrammatically the general layout of the installation under discussion. The furnace consists of a cast-iron shell lined with a suitable grade of refractory. Provision is made for water-cooled electrodes, through which power is furnished from a two-phase 440-volt a.c. line. Transformers and switchboard allow voltage changes in 10-volt steps, such changes being made either to control production or to adjust total power input as the internal electrical resistance of the heating bed varies from time to time.

A resistance bed of broken arc-light carbon is distributed over the entire cylindrical space between the electrodes. The heat generated is conveyed from the incandescent bed of resistor carbon to the charcoal above.

Sulphur is fed into the furnace from a melting kettle. It is fed through a liquid seal and delivered near the center of the hot zone, where it is vaporized instantly and reacts with the hot charcoal present.

Charcoal is introduced periodically as needed by means of a suitable hopper through the top of the furnace shell. Carbon bisulphide, hydrogen sulphide and other sulphur compounds leave the furnace and enter a condenser, where the bisulphide is recovered, and the impurities are washed out continually by means of overflow water.

Attempts have been made to control the temperature of the furnace by means of pyrometers. Peep holes, however, have proved fully as satisfactory, and represent considerably less maintenance costs. The usual maximum temperature is about 1,000 deg. C.

1. Charcoal hopper; 2. Furnace; 3. Refractory lining; 4. Charcoal; 5. Resistance carbon; 6. Electrode; 7. Delivery pipe; 8. Condenser; 9. Product.

*Paper presented at the forty-second general meeting of the American Electrochemical Society in Montreal, Sept. 21, 22 and 23, 1922.

The unit diagrammed above will produce 1 ton of carbon bisulphide in 24 hours with a power consumption of 0.5 to 0.7 kw.-hr. per pound of washed material recovered. The principal losses of electrical heat and chemicals may be listed as follows:

1. Radiation of heat from a surface of furnace, including electrode losses.
2. Loss of sensible heat in exit vapors.
3. Loss of heat due to melting and vaporization of sulphur which leaves the furnace as unreacted sulphur and worthless sulphur compounds.
4. Loss of chemical accompanying heat loss listed under 3.
5. Loss of carbon bisulphide due to leaks and solution in wash water.

Calculating Distribution of Heat Losses

In calculating distribution of heat losses, it is important to have available values for the chemical losses which represent heat consumption without the equivalent yield of product. It is fair to estimate a sulphur loss represented by items 4 and 5 as totaling 20 per cent of the original sulphur fed to the furnace. This is equivalent to an 80 per cent yield of washed carbon bisulphide, based on original sulphur used, and must be accompanied by an additional 20 per cent power consumption over that theoretically required for the production of carbon bisulphide actually recovered.

Knowing the radiating surface, average shell temperature and the recovery of carbon bisulphide per 24 hours, it is possible by making a reasonable assumption for the heat conductivity coefficient to estimate the heat loss due to radiation. Operating conditions at the plant considered warrant accepting as reasonable the value $K = 2$.

In order to calculate thermal efficiency, it is necessary to know the theoretical number of heat units needed for the formation of a unit weight of carbon bisulphide. It is also essential that we know the heat requirements for each of the steps of the reaction in question. This involves tabulation of data on latent heats, specific heats and heat of formation. Unfortunately, there are some discrepancies in physical constants reported, and it has been deemed advisable to record the values found in standard compilations. Such values are given in detail in the appendix. As far as the writer was able to ascertain, no direct measurements of specific heat of sulphur vapor has ever been made. There appears to be an agreement in values given for heat of formation of carbon bisulphide, starting with solid sulphur and carbon and finishing with gaseous carbon bisulphide. Koref has calculated from equilibria data the heat of formation of carbon bisulphide, starting with sulphur vapor, and has shown that such a reaction is exothermic rather than endothermic, as is the case when solid sulphur is used. The vaporization of the sulphur prior to its reaction with carbon demands enough heat to cause a change from an exothermic to an endothermic process.

Heat of Formation

Mellor gives the following conception of the equilibria involved in raising sulphur to 1,000 deg. C. This summarizes in qualitative manner the results of the investigations of Smith and others during the past 30 years.

$$\underset{\text{Solid forms.}}{\overset{94.5^\circ}{S\alpha \leftrightarrows S\beta}} \overset{120^\circ}{\leftrightarrows} \underset{\text{Liquid forms.}}{\overset{160^\circ}{S\lambda \leftrightarrows S\mu}} \overset{444.5^\circ}{\leftrightarrows} \underset{\text{Gaseous forms.}}{\overset{1.000^\circ}{S_8 \leftrightarrows 4S_2}}$$

It is evident from this that the the thermal data required include (1) the heats of conversion of $S\alpha$ (rhombic) to $S\beta$ (monoclinic), (2) the heat of fusion of sulphur, (3) the heat of conversion of $S\lambda$ to $S\mu$, (4) the heat of vaporization of sulphur, (5) the heat of dissociation of S_8 to S_2, and (6) specific heat data for sulphur over the range 20 to 1,000 deg. C.

It is impossible to calculate exact thermal requirements for each of these steps since we have no data for specific heat of gaseous sulphur, much less for the heat of dissociation of S_8 to S_2. Bearing in mind, however, that our distribution of heat losses must necessarily be only approximate, we may simplify the above course of events and, by making certain allowable assumptions, arrive at a value which will be well within the precision limits of the entire problem. The steps simplified may be taken as:

$$\underset{20^\circ\text{ C.}}{\text{S (solid)}} \rightarrow \underset{120^\circ\text{ C.}}{\text{S (liquid)}} \rightarrow \underset{440^\circ\text{ C.}}{\text{S (gaseous)}} \rightarrow \underset{1{,}000^\circ\text{ C.}}{\text{S (at 1,000° C.)}}$$

Based on constants listed in the appendix, these three steps from solid, to liquid, to gas, to high-temperature vapor show an investment of heat units for 64 grams of sulphur amounting to

$$1{,}750 + 29{,}390 + 10{,}700 \text{ cal.}^1 = 41{,}840 \text{ cal.}^2$$

The heat required to raise the equivalent 12 grams of carbon from 20 to 1,000 deg. C. is calculated as 3,530 cal.[3] It is evident that the sum of calories represented by these two preparatory steps does not indicate the heat units expended in forming the equivalent amount of carbon bisulphide, inasmuch as there is a return of heat due to the exothermic vapor reaction as well as a return of heat to the entire system due to a cooling down of reaction products to about 200 deg. C.

Thomsen's value of —26,000 cal. for the heat of formation of gaseous carbon bisulphide and Koref's calculated value of +12,500 (from sulphur vapor) are quite consistent with the above heat values.

Loss by Sublimed S and Radiation

For purpose of heat-loss distribution, we must estimate the heat lost due to sulphur which has been vaporized but not converted to carbon bisulphide. Such byproduct sulphur leaves the furnace at comparatively low temperatures and would not represent a loss of 41,840 cal. per 64 grams. It is safe to omit the superheating effect of the vapor, thus reducing the loss to 31,150 cal. per 64 grams of sulphur lost. A second subtraction of 1,750 cal. must be made in calculating electric heat loss, inasmuch as the solid sulphur is warmed up and melted by steam outside of the furnace. With a 20 per cent loss of original sulphur fed to the furnace, this electric heat loss amounts to 97,000 cal.[4] per kilogram of product.

Loss of heat due to vaporization of water from charcoal containing 5 per cent moisture is a small item, amounting to only 5,000 cal. per kilogram of product.[5]

Radiation of heat from the furnace shell is quite the largest single heat loss realized. The units under consideration have about 320 sq.ft. (29.7 sq.m.) radiating surface. The average shell temperature approximates 100 deg. C. With a room temperature of 20 deg. C. and a conductivity factor[6] of $K = 2$, the radiation loss totals 610,000 cal. per kilogram of product.[7]

[1] Assuming 0.3 for sp. ht. of gaseous S.
[2] See appendix "B."
[3] See appendix "C."
[4] See appendix "D."
[5] See appendix "E."
[6] K = B.t.u. per sq.ft. per deg. F. per hr.
[7] See appendix "F."

The heat requirements for the production of 1 kg. of CS_2 in the furnace described above may be summarized as follows:

	Cal.
1. Heat of formation[8] of 1 kg. finished CS_2	320,000
2. Loss due to drying charcoal	5,000
3. Loss of heat due to subliming S, which leaves furnace in worthless form	97,000
4. Radiation loss	610,000
Total electric heat input	1,032,000

The tabulated heat balance indicates a thermal efficiency within the furnace amounting to about 31 per cent. Converting calories to kilowatt-hours it is possible to express our results as 1 kg. of carbon bisulphide produced per 1.20 kw.-hr., or 1 lb. per 0.73 hp.-hr. These values agree well with actual operating data.

It is quite evident that the largest loss of power is due directly to radiation losses from the furnace. Any increase in capacity of the furnace tends to lower the per cent radiation loss and increase the efficiency. The maximum capacity or output per unit time is limited by the maximum allowable sulphur sublimation loss. A point may be reached where added load may increase prohibitively the cost of operation due to loss of chemicals, as well as increased maintenance costs. With current prices of chemicals and hydro-electric power, it may actually prove more profitable to operate the furnace at a somewhat lower thermal efficiency, and to sacrifice efficiency for equivalent financial return.

Summary

1. A comparatively recent process for the manufacture of carbon bisulphide is described.

2. Actual plant data indicate that these units operate with a reasonably fair thermal efficiency.

3. An approximation of thermal losses is submitted.

In conclusion I wish to acknowledge the valued assistance rendered by Gordon Cave, who assembled and reviewed critically all references available pertaining to chemical and physical constants.

[8]See appendix "G."

APPENDIX B

Note:—All calculations were made with slide rule.

Calculations for bringing 64 grams of 2 gram atoms of sulphur from 20 deg. C. to 1,000 deg. C.

1. 20 deg. C. to 120 deg. C.
   (64 g.) (0.18) (100 deg.) = 1,150 cal.
2. Fusion.
   2 gram atoms × 300 cal. = 600 cal.
3. Heating liquid sulphur.
   (64 g.) (444 deg. — 120 deg.) (0.3) = 6,240 cal.
4. Vaporization of sulphur.
   2 × 11,580 = 23,160 cal.
5. Heating sulphur vapor to 1,000 deg. C.
   Assume sp. ht. of vapor = 0.3
   (64 g.) (1,000 deg. — 444 deg.) (0.3) = 10,700 cal.

Total = 41,840 cal. needed to bring 64 grams of sulphur to 1,000 deg. C.

Note:—In the furnace described, the melting is done outside the furnace by steam. This leaves about 40,090 cal. to be furnished by electric heat.

APPENDIX C

To heat 12 grams of carbon from 20 deg. to 1,000 deg. C.
(12) (1,000 — 20) (0.3) = 3,530 cal.
All this heat is supplied electrically.

APPENDIX D

Electric heat loss due to 20 per cent loss of sulphur in process.
Heat loss per 64 grams of sulphur so rendered worthless = 41,840 — 10,700 — 1,750 = 29,390 cal.
With 80 per cent yield of carbon bisulphide based on sulphur, heat loss in furnace =

$$\frac{64\ (1{,}000)\ (0.20)\ (29{,}390)}{76\qquad (0.80)\qquad (64)} = 97{,}000 \text{ cal. per 1,000 g. } CS_2 \text{ produced.}$$

APPENDIX E

Electric loss due to distilling of moisture from charcoal.

$$\frac{12\ (1{,}000)\ (0.05)\ (608)}{76\qquad (0.95)} = 5{,}000 \text{ cal. per 1,000 g. of } CS_2 \text{ produced.}$$

APPENDIX F

Radiation loss from furnace per kilo of CS_2 produced.
$K = 2$ B.t.u.
$K = 905$ cal. per sq.ft. per hour per deg. C.
Production of furnace = 2,000 lb. per 24 hr.
Production of furnace = 83.5 lb. per hour.
1 kg. production requires 0.0263 hour.
Furnace surface = 320 sq.ft.
Average temperature of furnace surface = 100 deg. C.
Room temperature = 20 deg. C.
Then: Heat loss =
(320) (80) (905) (0.0263) = 610,000 cal. per kg. of CS_2.

APPENDIX G

Heat of formation of 1,000 grams carbon bisulphide starting with liquid sulphur and ending with gaseous carbon bisulphide =

$$\frac{(1{,}000)\ [(-26{,}000) + (1{,}750)]}{(76)} = -320{,}000 \text{ cal.}$$

Condition of the German Paper Industry

According to recent advices from the American Consul-General in Berlin and from the Consuls in Breslau and Frankfort on the Main to *Commerce Reports*, the paper trade in Germany is suffering at present from a serious shortage of materials, particularly newsprint. Owing to the low value of the German mark the importation of paper in large quantities is extremely difficult and the trade is compelled to confine itself largely to paper of domestic production. Paper prices are constantly rising, as are the prices on all commodities. Very little is being exported, and most of the mills are sold for months in advance.

This situation has made the position of newspaper publishers so embarrassing that many papers all over Germany have been forced to suspend publication entirely or have combined with other journals. Some that formerly had two or three issues daily now have only one.

The condition of the Silesian paper industry has recently become worse. Large deliveries of wood on separations have necessitated the importation of pulp wood from Czechoslovakia and Poland. Because of the uncertainty of rates of exchange, prices have continually increased. The leading manufacturers of wood pulp in the Breslau consular district state that they are not in a position to export and can scarcely produce enough for home demands.

The paper manufacturers are overrun with orders and cannot make deliveries because of the difficulty of obtaining raw materials. At present large orders for paper cannot be filled within the next 4 or 5 months. Toward the end of 1921 the buyers, anticipating a large increase in prices, placed heavy orders, and as a result the factories were completely sold out and had no stocks left on hand. In spite of the fact that production during the first 6 months of this year was on an average 60 per cent greater than during the same period of 1921, there is still a scarcity of paper.

German Prices for Cellulose and Paper

The price for cellulose has been set by the manufacturers at 170 per cent more than the August, 1922, price. The paper manufacturers demand three times as much for September deliveries as for August deliveries.

The following comparative prices, in marks, for 10,000 kilos (22,048 lb.) of print paper prevailed during the first 8 months of 1922: January, 70,000; February, 73,000; March, 82,000; April, 128,000; May, 159,000; June, 166,000; July 200,000; August, 280,000.

According to present information, 700,000 marks per 10,000 kilos will be demanded for print paper in September. This is 350 times the pre-war price.

Ordinary writing paper, which was quoted at 95 marks per kilo in July, 1922, advanced to 132 marks per kilo at the beginning of August, and increased still further to 192 marks per kilo by the end of August. During the same period ordinary business envelopes rose in price from 85 marks per 1,000 in July, 1922, to 145 marks per 1,000 at the beginning of August, and 450 marks per 1,000 by the end of August.

Modern Practice In Manufacture and Applications of Steamed Ground Wood

Part II of a Description of the Present Status and Practical Possibilities of This Process for Paper and Board Manufacture, in Which the Operation of a Modern American Plant Is Discussed

By A. O. Bragg

IN THE preceding installment of this article* the theory of steaming wood preparatory to grinding was discussed and the equipment used in a modern American plant was described from the wood room to the jordans. In the following pages, the operation of this equipment will be described, with special attention to the so-called operating kinks and practical considerations.

Wood Room

Wood room operations consist of cutting to the usual 2-ft. lengths and, where necessary, barking. Logs 2 ft. long are preferable for charging cookers, as mechanical complications and labor cost are increased by attempting to cook longer logs; hence this sawing should be done before the cookers are filled.

As previously indicated, barking may or may not be necessary, according to conditions. The determining factors are the type of cooker used and the product in which the pulp is to be used. For example, it would be needless and a waste of money to bark wood to be used in trunk board or as a filler in a board between two outside liners of other pulp, so far as appearance is concerned, and the strength of pulp from rough wood would not be appreciably less than from peeled wood. Ordinarily, when used for paper, it should be barked. For use in wrapping paper, for instance, where bark specks might cause holes in going through the calenders or detract from the appearance, the bark should be removed. No barkers will be needed with rotaries, as before stated, but barkers of some type are necessary with vertical cookers. Since the fine bark dust is not usually objectionable in the dark colored papers for which this pulp is suitable, the heavy wood loss from knife barking to obtain absolutely clean wood is not usually necessary. A fine grade of butchers' wrapping paper is being made of pulp from wood barked exclusively in the rotaries, where it is also steamed, the amount of slivers or brooming being very small and no bark being visible in the sheet.

Rotary Steamers

Below is given an operating schedule using rotary boilers 16 ft. in diameter, cooking for 12 hours, and providing for the maximum production from the equipment. It will be understood that the actual time in completing a cycle of operations is dependent on the time the wood is cooked. The equipment under consideration is that shown in Fig. 2.

Charging.—The chute is adjusted to discharge into the manhole of boiler to be filled by placing baffle board across the opposite side. The conveyor is started and boiler filled with 6 cords of rough or 7½ cords peeled wood from wood room. Then the conveyor machinery is stopped and a square-braided hemp gasket placed on the seat of the manhole cover, after which the manhole cover is lowered in place by Triplex block and the bolts tightened.

Cooking.—The reducing valve is set at pressure to be used for the cook and the steam turned on. The boiler is kept stationary until the charge is ready for barking. If boiler is tight, it requires about 1½ hours to get steam up to 20 lb. pressure. If boiler is not tight, leaks will prevent pressure building up at all. Condensed water is drained out every hour.

Barking.—About 1½ hours before the end of cooking time the boiler is started rotating and kept going until end of cooking period.

Dumping.—The cooker is stopped in such a position that the manhole cover can be reached by the Triplex block chain and lifted off. Then the boiler is started rotating again and this is continued until the cooker is empty. Rotation should be stopped in such a position that pulpwood will drop into manhole from chute for the next cook. It takes about 1 hour to dump a digester.

The barking is quite effective, only about 3 to 5 per cent of the logs having any bark still clinging to them and this bark is much disintegrated and loosened.

Dumping is rather a dangerous operation. At each revolution of the boiler more or less wood falls out together with finely divided bark. While the outlet is down and the digester is discharging, the workman must stand aside, out of reach of the falling logs. During the upper half of the revolution he "picks" logs onto the conveyor which takes the steamed wood to the grinders. When the pile accumulating on the high end of the slope gets too high, the wood falling from the boiler tends to push this pile down the slope toward the conveyors, and this danger must also be watched. Since the rate of dropping exceeds that at which one man can "pick" logs onto the conveyor, it is customary to stop the boiler until the accumulated pile has been disposed of, which time is included in the hour specified above. The number of logs dumped out at each revolution varies, as sometimes the manhole clogs up, owing to the arrangement of the logs inside. Much of the bark finds its way to the rack, being carried onto the conveyor while "picking" the logs. The excess bark is shoveled out through an opening in the wall of the pit kept closed by a door (Fig. 2) and thrown away. Its fuel value is low, because of the high moisture content.

Vertical Digesters

The operation of these cookers will be for the most part self-evident from the drawing. The wood bins are refilled while cooking is going on, dropping just enough wood over each cooker to fill it, which amount is measured in the wood room before putting on the conveyors. It should be mentioned that, when filling, some logs do not fall into the opening in the cookers, but fall on the floor. These must be put in by hand after the proper cordage has been dropped from the bin. As there is considerable danger from falling logs, no

*The first installment of Mr. Bragg's article was published in *Chem. & Met.*, vol. 27, No. 16, p. 793, Oct. 18, 1922.

workmen should be permitted on the third floor during the time logs are falling from the bin.

Dumping is practically instantaneous when the conical bottom has been lowered far enough to permit the logs to fall out. There is no occasion for anyone to be in the discharge pit, except to clean it out during shutdowns; hence there is no danger to the workmen from dumping. The hydraulic ram is provided with automatic stops. The pressure or temperature gages being on the first floor, the cooking requires very little time or attention, pressure or temperature readings every hour or so being all that is necessary.

As with the rotary, the steam should be passed through a locked pressure-reducing valve before admission to the boiler, to prevent possible explosion. At the end of a cook the steam remaining should preferably be blown off into boiler feed water by an insulated pipe going to the power plant and the whole steamer should be thoroughly insulated by suitable magnesia covering.

Bache-Wiig Process, Enge Process

The Bache-Wiig process[2] consists of boiling the blocks under pressure in a salt solution for 6 or 7 hours. This is said to exert a peculiar softening effect on the wood, the fibers disintegrating more readily with scarcely any loss in weight and a much stronger white pulp being obtained which takes color well. It is claimed that by the use of such pulp alone, a sheet fully as strong as one made of 80 per cent ordinary ground wood and 20 per cent sulphite may be obtained. The extra cost per ton, figuring on a 100 ton per day production, is estimated at $0.99 in 1916, necessitating for the processing alone a plant investment of $72,500. It is stated that the use of 5 per cent of sulphite is advisable with newsprint because of the better finish obtainable. The savings using 5 per cent sulphite and 95 per cent Bache-Wiig ground wood, as over 25 per cent sulphite and 75 per cent ordinary news ground wood, are estimated at $3.25 per ton.

The Enge process,[3] German patent 315,679, claims the production of a very tough ground-wood fiber with absolutely no discoloration—i.e., the color is that of the natural ground wood. The results obtained from tests on Enge pulp by the Laboratory for Testing Materials do not bear out these claims. In this method the wood is saturated with water at 80 deg. C. and kept boiling for 6 to 8 hours under a ½ atmosphere pressure. Grinding is done lengthwise, the axis of the log being kept at an angle of 10 deg. to the face of the stone, which increases the fiber length.

The pulp is darker in color than untreated pulp, but not so dark as steamed pulp. As would be expected, the process is rather slow. The breaking strength of newsprint made wholly of Enge pulp was found to be slightly more than for ordinary newsprint, but because of the brittleness of the pulp was much inferior to it in the number of foldings it would stand.

The advantages of the Enge process over ordinary wood steamings are not very evident, and it would seem that the relatively slight treatment which could be given to wood by it, necessary to keep the pulp from becoming too dark in color to be used for newsprint, would not effect benefits commensurate with the cost of treatment. The Bache-Wiig process is based on a scientifically correct foundation, the sodium chloride uniting with the brown coloring matters formed, to give water-soluble sodium salts of these dyes and thus preventing the discoloration of the pulp caused by Enge's process. However, with the recent advent of improved methods of dressing stones to obtain ground wood of sufficient strength for use in newsprint without sulphite, the investment and operating costs for the Bache-Wiig process would seem to be too heavy as compared with these more recent developments.

Proper Cooking Conditions

A generally inclusive and definite statement as to the proper cooking conditions to be used with different woods cannot be formulated, the number of variables being too large. The exact conditions are something which each mill must decide for itself. All the following factors have a bearing, directly or indirectly, on how long and with how much steam pressure a given wood should be cooked:

1. Moisture content of wood.
2. Pitch or rosin content of wood.
3. Seasoning the wood has had.
4. Time of year in which wood is felled.
5. Density of wood species used.
6. Soundness and freedom from decay and fungi.
7. Diameter of logs.
8. Color of pulp desired.
9. Strength of pulp desired.
10. Product in which pulp is to be used and its requirements as to color, strength and finish.
11. Paper machine equipment available and production desired from it, and if addition and alterations can be made to it to increase production.
12. Balance of cost—i.e., striking a balance between maximum strength or depth of color of pulp desired and permissible limit of cost for steaming operation (which involves yield per cord) and whether a slight increase in strength obtained by cooking beyond a certain period will not be offset by greatly increased cost and reduced yield.

The relative influence of these factors will perhaps be more evident after giving some present cooking practices used with different woods and for different products, describing the nature of the pulps obtained and the operation conditions for the machines.

Wrapping Paper

The first woods considered will be a mixture of scrub pine and white pine. These woods are now being used for pulp to make an excellent grade of butchers' wrapping paper. The cooking conditions are varied according to the condition of the logs, as determined by visual inspection and personal judgment. The limits are from 9 to 16 hours at 13- to 20-lb. gage. All dry, well-seasoned logs are treated for 9 to 12 hours at 13- to 16-lb. pressure; all green, freshly felled wood requires from 16 to 20 lb. applied for 12 to 16 hours. Mixtures of dry and green woods are treated in proportion to the amounts of the woods of different moisture contents present. Thus, a mixture of equal parts green and dry wood would be cooked at 16.5 lb. for 12.5 hours, the mean of the maximum and minimum limits. If all the wood was extremely green-steamed—for instance, the day after cutting in the spring when the sap is up—20 lb. for 16 hours or longer would be required to effect thorough saturation and freeing from pitch, while if all the wood has been stored in a dry place for 3 or 4 years, 9 or 10 hours at 13 lb. would be sufficient. Under these conditions 8- to 9-in. sticks are completely saturated, all rosin and pitch removed and suitable pulp obtained. Larger sticks are likely to be incompletely penetrated and to have some rosin still present. If many such logs are noticed in the wood room when sawing, they should be split before cooking.

[2] *Paper*, April 19, 1916.
[3] *Paper*, Sept. 6, 1916.

In grinding, any good medium grit stone is used. Like any ground wood, the quality of the pulp depends largely on the dressing given the stone and the production on the speed and pressure used. In this case, an 8 to 1-in. diamond burr is used, keeping the stone dull. The pressure is 60 to 70 lb. to avoid the crushing effect on the fibers by higher pressures especially noticeable in dull stones. At these pressures a stone will grind about 4½ cords per 24 hours with a three-pocket grinder. The yield is about 2,200 lb. of pulp per cord, which corresponds to a 24-hour production per grinder of 5 tons of pulp. The power consumption per grinder runs from 280 to 290 hp., or 56 to 59 hp. per ton per 24 hours.

For the wrapping paper mentioned above, 60 per cent sulphite and 40 per cent of the steamed pine ground wood are furnished. It is found that this paper takes and keeps a better finish and has a higher Mullen test if the pulp is cooked as above than if it is steamed at a higher pressure for shorter periods.

This ground wood, and any ground wood made from wood of similar fiber length similarly treated, can be classified as an exceptionally strong and high grade of ground wood, except, of course, as to color. It is much stronger and tougher than any untreated ground wood made from wood of the longest fibers, in spite of recent developments in stone dressing. It is still considerably weaker than sulphite. An attempt was made to produce butchers' wrapping paper from the steamed ground wood alone, but the sheet was found to be too low in tensile strength, and the above formula was adopted. Even using only 40 per cent steamed pulp, 40 per cent sulphite is replaced and its cost and freight saved. The heavier weights of this grade of paper can use a higher percentage of steamed ground wood than this, a 60-lb. sheet being perfectly satisfactory when containing 75 per cent steamed ground wood and 25 per cent sulphite. The stock dries well on the driers. As much as 46 tons of this paper, basis 24 by 36, 60 lb., can be made on a Fourdrinier trimming 105 in. with twenty-six 48-in. driers.

The pulp is a maple or tan color, verging on the orange. It is found from experience that when cooking these pines for longer than 20 hours the increased cost and darkening of the fibers offset the slightly improved Mullen and tensile strength obtained, so that this figure can be considered as an economical maximum for cooking time for similar woods. The fibers are long and the pulp is tough and tears with difficulty. It seems to be a trifle softer than untreated pulp when dry. For use in this kind of paper, careful jordaning is relied on to keep up the Mullen of the sheet, rather than the beaters, as previously mentioned. The Mullen test obtained from this pulp alone, with a Fourdrinier formation, is about 4 lb. per 0.001 in., which is rather more than would be obtained on the usual cylinder machine. The stock is kept very thin, 0.110-in. centrifugal screen plates being used.

Use in Board

Some cylinder machine applications of steamed pulp will now be considered. These include quite a variety of board products, such as wallboard, trunk and suitcase board, leather board, various container boards, etc., where the color is not objectionable and the pulp can replace more or less unbleached sulphite. It also serves to increase the strength over that obtainable from ground wood or waste papers. It is not sufficiently strong to replace any pulp stronger than sulphite.

Spruce, steamed at 50 to 55 lb. for 14 hours, and a mixture of birch (50 to 75 per cent) and maple (50 25 per cent), or either alone, similarly treated, yie pulps particularly adapted to make certain stror boards. This steamed spruce ground wood is now su cessfully used alone for solid jute boards in its natur color. Such boards are not brittle, are tough and a good benders. The color of the pulp, and hence of th boards, varies from a light to dark tan, sometimes wit a slightly reddish cast. Used as outside liners in fille jute board, the bending quality is improved, and th strength of the board increased over plain chip for th same caliper. All these boards take and retain a goo water finish and are good imitations of genuine jut Spruce and other coniferous woods are steamed unde the above conditions for the production of brown pul for suitcases, trunks, etc., and for use as a filler in th manufacture of leather board, mill board, etc.

Pulping Hardwoods

The pulp obtained from grinding hardwoods whic have been steamed as above is quite different in som respects from steamed spruce pulp. With both th hardwood and spruce a 6 to 1-in. diamond burr is usuall used, keeping the stones dull. The more seasoned an drier these woods are the less cooking they require Wood seasoned for 3 years, which is apt to be rathe punky, would be steamed for 14 hours at 30 lb., whic can be considered as the minimum limit for this clas of pulp.

Steamed hardwood pulp is of small tensile strength tender and very likely to cause trouble in lapping and o the paper machine owing to these characteristics. Whe dry it makes a very rigid but brittle sheet. While th fibers are short and lack the felting power of steame spruce, they are still not as slow as the steamed spruc ground wood, which is conceded to be one of the mos difficult stocks to handle on a cylinder machine. Th "footage" obtainable from the steamed hardwood i comparatively good in spite of the density and weigh of the pulp. The cooked hardwood logs are best groun with steamed spruce wood in the proportions of on pocket of steamed spruce and five pockets of steame hardwood. This permits lapping on the wet machine an easier running on the cylinder machine owing to th added tensile strength from the steamed spruce. In som cases the cooked spruce can be omitted from the grind ers and 20 to 30 per cent of natural ground wood an 5 to 10 per cent sulphite pulp used to give strengt and freeness to the stock and prevent machine trouble Though steamed hardwood pulp has a low tensil strength, the Mullen test of boards made from it run high on account of their great rigidity.

This pulp is much different in color and darker than steamed spruce, being a rich chocolate shade. For thin boards which must have both puncture resistance (rigidity) and tensile strength, a sheet made up of equa caliper plies of cooked spruce and cooked hardwood makes an excellent combination. Used as a filler and bottom liner, with a top liner of natural ground wood and sulphite in suitable proportions, very strong yet attractive looking boards are made. Where very thick heavy boards of extreme rigidity are desired, three o four plies of steamed hardwood boards, pasted together with sodium silicate on a sheet pasting machine, wil give a product with almost the rigidity and smoothness of solid wood, suitable for making the largest and strongest trunks and for other products which may be subjected to extremely severe usage.

Wallboard made entirely from steamed wood pulp would be too expensive, owing to the large weight per square foot giving small "footage" per ton of board; but one or two cylinder plies on the inside add much to the strength and rigidity so important in these products. The use of steamed ground wood in products of this character is patented.

Since all steamed ground-wood pulps are very slow, as compared with untreated wood similarly ground, some suggestions regarding proper construction and operating conditions for the paper machine might be of help. Owing to the difficulty in handling this stock on the machine, the machine crews must be of the very highest caliber and skill, preferably those who have previously handled slow stock on multicylinder machines.

In the first place, because of the slowness of the pulp, it is imperative that as little stock as possible be applied to any one cylinder mold in building up the sheet. This smaller amount permits the water to drain out more quickly from the greasy stock, thus reducing the likelihood of "blows." "Blows" in board are usually caused by an outside cylinder ply being more compact and thus slower than the filler stock. Consequently the press rolls cannot squeeze out the water from the liner fast enough, but instead the water in it acts something like a lever, forcing the liner from contact with the filler ply.

Referring again to the necessity of applying as little pulp as possible to each cylinder mold, in order that thick boards may be made, machines with unusually large numbers of cylinders are used. Trunk board, for instance, is made of steamed spruce and hardwood applied to from nine to twelve cylinder molds, rarely or never less than nine. As an approximate estimation of the caliper of dried pulp applied by each mold, this should run from 0.003 to 0.004 in., as contrasted with 0.005 to 0.006 in. for waste paper boards and 0.006 to 0.007 in. for coarse free ground-wood stock such as wallboard single-ply, for which six cylinders are used in place of nine or more.

Size of Vat Circle Important

Another important factor in construction is the size of the vat circle—the radial distance from the cylinder mold wire to the inside surface of the cylinder vat lining. If this clearance is small, say 3 to 4 in., especially with very wet stock, the fiber will be so compact that a dense, heavy, wet sheet is formed from which the water is very slowly removed; while a clearance of 6 to 8 in. makes a sheet which, while not giving quite the finish of the more compact stock, gives greater production and less trouble because of being freer and more open. The "footage" of board obtainable per ton of pulp will be greater, since it will run lighter in weight per unit of caliper.

To permit free and quick passage of the water pressed out, the felts used should be as open and coarse as consistent with the requirements of the sheet as regards smoothness and felt marks. All couch rolls, baby press rolls and main press rolls must be kept in perfect condition and alignment to prevent damp spots and streaks in the sheet.

The satisfactory operation of a board machine on this pulp involves more difficulties than a Fourdrinier. Using slow stock on a Fourdrinier, the suction is increased on the suction boxes and suction press roll. In a multicylinder steamed ground-wood board machine, the suction on each cylinder mold must be reduced and kept uniformly so, by lowering the head to 3 to 4 in. or less as compared to 13 to 14 in. on free stock. The driers must be regulated to dry the sheet slowly and gradually, to avoid blistering.

Where the quality and thickness warrant, refined ground-wood screenings are useful in reducing weight and freeing up the stock, and are cheap; refined sulphite screenings, though darker in color and more expensive, both free and increase the strength of the stock.

The following estimate of production possible from a cylinder machine operating on steamed pulp is probably conservative. If a machine making 90 tons of a pure uncooked spruce ground-wood board were put on 20 per cent refined ground-wood screenings and 80 per cent steamed ground wood, by working much harder the machine crew could maintain an output of about 75 tons.

General Considerations in Cooking Conditions

Table I summarizes the cooking practice for the various woods considered in this article and will be found suggestive in deciding on how best to cook a given wood for certain uses.

TABLE I—SUMMARY OF COOKING PRACTICE

Wood	Length of Cook, Hr.	Steam Pressure, Lb.	Natural Fiber Length, mm.	Color of Pulp	Tensile Strength	Other Characteristics
Maple, Birch:						
Dry	14	30	1.5	Dark	Low	Rigid. Brittle.
Green	14	50 to 55	1.5	Chocolate	Low	Compact. High Mullen. Tough.
Spruce:						
Dry	14	30	2.8	Light to	High	Elastic. Good bending.
Green	14	50 to 55	2.8	dark tan	High	Not so rigid as hardwood.
Scrub pine, White pine:						
Dry	9–12	13 to 16	2.8	Same as	High	Same as for spruce
Green	12–16	16 to 20	2.8	spruce	High	pulp.

Considering again the twelve factors determining cooking conditions, the fundamental one is No. 10—"Product in which pulp is to be used and its requirements as to color, strength and finish." This automatically specifies the color or strength the pulp must have and hence pressure and duration of cook that will give them.

In carrying out the trial steaming tests to determine the best conditions, no logs should exceed a certain maximum diameter, say 8 to 9 in., and their moisture content should be approximately constant for all test runs and either be extremely green or extremely dry, preferably the former, as the wood of high moisture content will require the most severe conditions. Practically, this means that all the wood used should have been felled at the same time of year and have been similarly dried afterward, if seasoned wood is used. In this way all the data obtained will be of unquestioned value for the purpose. Moreover, the wood should be of the same species or at any rate of species of practically equal densities. Steaming, grinding and machine runs under these known conditions having been carried out and all pertinent data recorded, if a satisfactory product has been obtained, factors 11 and 12 can be considered and the conditions modified so far as possible to conform with these two factors. As a final step in the standardization process, satisfactory cooking conditions should be found for woods containing the opposite extreme of moisture to the original content selected.

In connection with factors 11 and 12, dealing with the construction and financial conditions at the mill, the following may be of help. Practical economic considerations would dictate that the total cost for the steaming operation alone (not including wood preparation but including everything from power to elevate wood to cookers, to labor or power to take steamed wood to grinders) should not be more than three-quarters of the difference between the cost of natural ground wood and No. 2 unbleached sulphite pulp. Above this fraction of the difference in cost it would doubtless pay in the long run to use the unbleached sulphite rather than make steamed ground wood at all. Ground wood is now $32 a ton and No. 2 unbleached sulphite $48, a difference of $16. Three-quarters of the difference, or $12, is therefore the economical limit. There are practically no cost figures available on the steaming operation, and conditions vary greatly, so that such figures would not mean very much at best. The following data may help in approximating such cost:

1. Interest on investment would be comparatively small, a few cents per ton with rotaries; but would be much larger with the building, wood bin, conveyors, cookers and miscellaneous equipment necessary when the vertical type is used. The operating cost exclusive of interest charges would be less for the vertical type. Vertical cookers or steamers of the type and size indicated in the drawing can be obtained now for $5,050 each. Two would probably be necessary for most economical operation, as previously pointed out.

2. Steaming at 15 to 20 lb. for 15 hours, using unjacketed rotaries and not reclaiming residual steam by absorption in boiler feed water, the coal consumption is estimated to be ¼ ton coal per cord steamed. At an evaporation of 9 to 10 lb. water per pound of coal, this would figure out as 4,000 to 4,500 lb. steam per cord of wood. At a yield of 2,200 lb. AD pulp per cord, this would be 0.227 ton coal per ton AD pulp.

3. Where wood must be barked before cooking, two men per shift are required. Where unbarked wood can be used, one man per shift is sufficient. In both cases it is necessary that they devote their entire time to duties directly and indirectly connected with its operation.

Control of Operations

Satisfactory cooking conditions once having been worked out for a particular mill, care should be exercised to see that no woods varying widely in density from that considered in the standard conditions are used. Care should be taken that no wood with unusually large amounts of pitch are cooked under conditions suitable only for smaller amounts of pitch. Of course the moisture content of the logs will have to be watched and conditions varied as may be necessary. If the wood seems to be unusually wet or dry, occasional moisture determinations will aid in avoiding undercooked wood and machine trouble. The value of the product, as compared to higher grades of pulp, is not enough to warrant any great expenditures for elaborate control work for moisture, yields, etc.

Possible Future Applications of the Process

Steaming hardwoods and pitchy woods, neither of which give satisfactory ground wood in the untreated state, would seem to offer fields for wider use of the steaming process, to replace, in part, unbleached sulphite in locations where few of the local woods are adapted to the sulphite process.

Woodford, Me.

Groove Inspection of Thermit Welds

By J. H. Deppeler
Chief Engineer, Metal & Thermit Corporation

ONE fact that has been responsible more than any other for retarding the progress of welding is that when a weld is made it has been impossible to determine without destroying it what strength is definitely assured and safe to allow. An examination of the surface of welds does not reveal this. For example, in gas or arc welding, the operator can carelessly leave voids and laminations during the work, and yet finish the surface of his weld so smoothly that these cannot be detected. To show another example, there may be numerous burned spots and other oxide inclusions which are hidden and yet render an apparently strong weld

FIG. 1—GROOVES CUT IN COLLARS OF THERMIT WELD MADE IN 9x10-IN. BARS

absolutely useless. It is on this account that technical societies and associations interested in the possibilities of welding have greatly restricted the permissible applications to parts which are stressed relatively light, or in those whose failure will involve small risks.

It is highly important, therefore, to consider the fact that Thermit welding permits the drawing of proper conclusions as to the strength of welds. If the proper amount of Thermit has been used and the work has been done by a skilled operator, it is impossible to have such defects as lack of fusion. Oxide inclusions, such as those formed during the preheating and adding of weld metal, or those remaining on unclean surfaces (due, for example, to failure properly to clean scale from wrought-iron sections before welding) have always resulted in Thermit welding in only one type of defect—i.e., blow holes. Due to the natural tendency of the gases to rise in the molten mass, this defect, if present at all, will always be present in the Thermit steel collars. It is apparent that an examination internally of the collar or excess metal can be made without affecting the strength of the weld. Thus the unsound welds can be found and condemned.

In practice, this examination is made as shown in Fig. 1 by gouging deep grooves in the collars parallel with the axis of the piece, these grooves reaching almost to the original sections itself. It is unnecessary to cut as many as shown, since we have found that two such grooves on the four sides of a Thermit weld are sufficient. If these grooves are observed to be free and clean from blow hole defects, the inspector may be assured that the weld itself is sound.

New York City.

Synopsis of Recent Chemical & Metallurgical Literature

Deterioration of Stored Cement

Details of a study of the storage and transportation of portland cement, with a bibliography on the subject, are given in Serial 2,377, obtainable from the Bureau of Mines, Washington, D. C. Deterioration of cement stored in bulk is less than in bags, owing to the smaller area exposed, states the United States Bureau of Mines, as the result of an investigation to determine the cause of deterioration of portland cement during storage and transportation. Hydration takes place only at the exposed surface, and the bulk of the cement is unaffected. Cement transported in bulk must be shipped in a tight, closed car, and must be protected from moisture during loading, shipping and unloading. Preferably it should be used immediately after unloading at the point of destination. This practice is now followed by several manufacturers and where conditions are suitable it is becoming more common as its advantages are seen. Shipping in bulk effects a saving by eliminating the use of bags which is an important item in the cost of cement—and it should also permit a saving in freight rates.

Air Conditioning in a Munitions Factory

A criticism of the technical literature on the subject of air conditioning, on the ground that it is deficient in detailed and critical study of the actual performance of recognized ventilation systems under the normal conditions of everyday use, introduces a pamphlet which has just been issued by the United States Public Health Service and written by C. E. A. Winslow and Greenburg. It is said that the details of installation are recorded in technical literature very fully, to the neglect of the results obtained in actual everyday operation. The authors have carried out investigations in a munitions factory which included over one hundred separate buildings. The greater number of the workrooms involved no special air conditioning problems and furnished good examples of the ordinary factory workroom ventilated by windows only, but thirteen of the workrooms studied were equipped with systems of fan ventilation, many of them designed to combat heat hazards of considerable magnitude.

It was found that in most of the rooms requiring no special ventilation the general tendency was to maintain a temperature slightly above optimum working conditions. A temperature of 68 deg. F. should be maintained and it is said that the systematic observation of a thermometer placed in every workroom and the intelligent regulation of heating appliances are all that is necessary to provide this condition. In other words, to quote the words of the authors, "A thermometer and a little common sense will solve a great many ventilation problems."

A problem was encountered in the annealing shop, which contained a large number of rotary furnaces on each side of the room. The temperature in these furnaces was about 1,200 deg. F. A system involving two air washer fans, each having a capacity of 45,000 cu.ft. per minute, was arranged to deliver air to both sides of the room at the floor level, with another duct along the center of the ceiling. It was found that this system was amply sufficient to keep conditions good when the weather was cold, although the CO_2 content of the air rose to as high as 14 parts, due no doubt to the presence of furnace gases. Other detailed studies were made in the shell-washing shop, where the heat and humidity were controlled by fan ventilation. Curves are given which show very plainly the changes in atmospheric conditions in this wash shop caused by interrupting the fan ventilation. In general, it is concluded that while conditions in this workroom under normal operation were by no means ideal, the temperature being sometimes over 80 deg., they would be almost unbearable without the very efficient system of ventilation that has been installed.

In conclusion, the authors state that in the summer time while the hazard incident to processes involving the production of excessive heat can and should be mitigated to some extent by a system of ventilation which produces vigorous air movement, it cannot be fully controlled except by special systems of air cooling which involve considerable expense, but which must be accepted as an inevitable incident of certain industrial employments. Where this is the case, the effect of the high temperature should be minimized by short spells of work alternating with rest.

Tellurium and Its Uses

Detailed information regarding the properties, uses and metallurgy of tellurium is given in Serial 2,385, by H. A. Doerner, chemist, which may be obtained from the Bureau of Mines, Washington, D. C.

The finding of new uses for the mineral tellurium would render marketable a byproduct of which the copper refineries of the country can produce 125,000 lb. annually but for which there is little present demand. Although the mineral possesses various rather remarkable characteristics, present uses are so limited that the demand is supplied by a few hundred pounds per year.

Most gold and silver ores and particularly copper ores contain tellurium. In the course of smelting and refining these ores, tellurium is found in concentrated form in the flue dust of smelters, electrolytic slimes, and in the fumes and slags resulting from cupellation. The whole commercial supply of the element is obtained as a byproduct from copper ores. Pyrite and sulphur used in the manufacture of sulphuric acid also contain tellurium, as it is found in the flue dust and acid sludge of acid plants. Tellurium minerals are found in Transylvania, Hungary, Spain, Brazil, Bolivia, Chile, Mexico, Japan, Australia, California, Colorado and Virginia.

Efforts have been made by government agencies in co-operation with copper refiners to discover new uses for tellurium, but no important results have been reported. It has been used in a small way in high-resistance and other alloys, in organic dyes, for staining silver, in medicine and as a reagent in chemical laboratories. As a coloring agent in glass or porcelain, blue, brown and red colors may be produced by tellurium, some of the best ceramics being colored in this way. Tellurium dissolved in sodium sulphide solution is used in toning baths for photographic prints. Tellurium dioxide at red heat is a powerful oxidizing agent, decomposing completely even lumps of steel or metal alloys. Its chemical similarity to sulphur suggests many possible uses. It might be used, for instance, as telluride in coloring lithopone, and the extension of the use of tellurium might well be studied in connection with the iron and steel industry. The Bureau of Mines considers there is undoubted promise in experimentation with tellurium compounds in the field of organic medicinals, while their physiological action in derivatives similar to those of sulphur and selenium has not yet been developed. In compounds similar to selenium oxychloride, tellurium may provide valuable laboratory reagents.

The use of 0.2 per cent diethyl telluride in gasoline as an anti-knock compound has been reliably reported. It is said to eliminate carbon deposits and to produce greatly increased efficiency when used in motors designed to operate on very high compression. A special type of engine is said to be required to produce these results, hence its general use in motors will not be feasible unless the motor industry should conform to the required type. This step in turn would be dependent on a supply of tellurium adequate to treat all the motor fuel. For this purpose, 1,500 tons of tellurium per year would be required, and as the possible annual supply of tellurium from the present best known sources of copper refineries is said to be only about 125,-

000 lb., a much larger supply must be developed; the discovery of new uses not dependent on so large a supply would result in wider utilization of present resources.

Tellurium is usually offered in the impure state, and no market standards have been developed. No ores are known that are rich enough in tellurium to permit mining and treatment for tellurium alone, even if the demand increased to large proportions. It is probable that the future supply will be derived as a byproduct from metallurgical processes, as in the past.

Samples of tellurium for research purposes may be obtained from the Committee on the Uses of Selenium and Tellurium, National Research Council, Washington, D. C.

Comminuted Smokeless Powder for Blasting

Information regarding the physical properties of comminuted smokeless powder and instructions regarding the handling, packing and use of the explosive are given in Serial 2,386, by C. E. Monroe, chief explosives chemist, and Spener P. Howell, explosives engineer, recently issued by the Bureau of Mines.

Tests made by the bureau show that large supplies of smokeless powder left in the possession of the federal government at the close of the war can, in the form of comminuted smokeless powder, be used effectively for certain industrial blasting purposes. Field tests made by the bureau at the explosives experiment station at Bruceton, Pa., have demonstrated the practical value of this powder for stump-blasting, boulder-breaking and ditch-digging purposes. As the result of experiments previously made by the Bureau of Mines looking toward the industrial utilization of other types of military explosives, more than 34,000,000 lb. of surplus trinitrotoluene, 13,000,000 lb. of picric acid and about 1,000,000 lb. of grenade powder have been allotted by the War Department to other departments of the government. These allotments have been used in industrial blasting and also on a great variety of government projects, and gave entire satisfaction.

The problem for smokeless powder is unlike that for TNT and picric acid. Both the latter are detonating explosives used to break up the shell, or other devices containing them, into fragments which act as missiles; smokeless powder is designed to take the place of black gunpowder in driving the projectiles from guns. Hence smokeless powder is a propellant, and an essential of a propellant is that it functions by progressive burning, not by detonation, as detonation within a gun would probably burst the gun.

From the time of the entrance of the United States into the war until its conclusion there was produced in this country 632,504,000 lb. of smokeless powder; at the declaration of the armistice one factory alone of our many factories had a daily capacity for production greater than the entire annual capacity of the country prior to the war.

The adaptation of smokeless powder to use as an industrial blasting agent is due to the discovery by Major John Herbert Hunter, Ordnance Department, U. S. A., that when smokeless powder is ground to fineness the ground material can be detonated by No. 6 detonator, and therefore may, in this condition, be used as a blasting agent. Major Hunter has dedicated to public use in the United States the patent granted to him for this discovery. Therefore all are free to use the process without payment of royalty. In his specifications Major Hunter points out that the rate of detonation of this comminuted smokeless powder varies with its fineness as measured by sieves of 8 to 80 mesh; it is possible, then, by regulating the grinding and sieving, to prepare explosives having different but determined rates of detonation, thus suitable for various kinds of blasting. He provides that in use this comminuted smokeless powder shall be packed in cartridges, as is the practice with dynamite. The product is styled "comminuted" because this term is broad enough to include any and every method of subdividing the grains without destroying their chemical identity.

As the gaseous products of detonation include poisonous and flammable carbon monoxide, comminuted smokeless powder is unsuitable for use as an explosive in dusty and gaseous coal mines or in other places where flammable dust, gases or vapors may be encountered. Nor should it be used in mines, tunnels or other close places, unless the ventilation is very good and workmen are not in contact with the poisonous gases produced by it. Comminuted smokeless powder has a pale yellow color with an earthy luster. It is tasteless, odorless and insoluble in water. When touched by the tongue, it gives the sensation imparted by dry earth or chalk. Being insoluble and non-volatile, it is not poisonous, and so far as this characteristic is concerned, it may be handled with impunity. It does not melt when heated, but it is very flammable and easily ignited.

South Carolina White Clays

The methods of mining and preparing white clays for market in the vicinity of Langley, S. C., are described in Serial 2,382, by W. M. Weigel, mineral technologist, just issued by the United States Bureau of Mines. Langley is about 9 miles north of Augusta, Ga. The clays mined in this district are sedimentary kaolins with few impurities. The prevailing color is white; at times the color is smoky gray or pink, and occasionally strong pink to lavender. The lighter colors usually become white on exposure to the air and on drying. The lower parts of the beds are usually the whitest. These kaolins are fine grained in texture, and have good plasticity; their tensile strength is from 8 to 36 lb. They generally slake readily. Their specific gravity is from 2.50 to 2.25. The clay in the district are well adapted for us in paper stock, for which they ar mainly used, and in pottery and china ware, without washing. In the district as a whole considerable reserves of cla are yet untouched, hence the industr can be considered fairly stable.

Copies of Serial 2,382 may be ob tained from the Bureau of Mines Washington, D. C.

Tests on Miguet Process for Obtaining Alumina From Clay

As a good grade of clay contains fro 30 to 40 per cent of alumina, the pros pect of recovering it is alluring an proposed methods are appearing con stantly in the patent literature. Typi cal of these is U. S. Patent 1,376,56 granted to Paul Miguet. He propose to prepare an alkaline aluminate b fusing clay, lime and scrap iron with reducing agent in the electric furnace the reactions being supposedly as fol lows:

(1) $Al_2O_3.2SiO_2 2H_2O + Fe + 4C + CaO = CaO.Al_2O_3 + FeSi_2 + 4CO + 2H_2O$

(2) $CaO.Al_2O_3 + Na_2CO_3 = Na_2O.Al_2O_3 + CaCO_3$

The sodium aluminate thus obtained readily yields aluminum hydroxide while the ferrosilicon should be a profit able byproduct.

So many reactions similar to the above have been proposed and it is so popularly believed that alumina can be obtained from clay by fusion that the Northwest Experiment Station of the Bureau of Mines at Seattle, Wash. undertook to investigate the Miguet process. The results are recorded in *Reports of Investigations*, Serial 2,393 by Clyde E. Williams and Clarence E. Simms.

The tests were carried out in a car bon-lined pit furnace of the Girod type having a tap-hole to remove the fused material. Clay containing 38 per cent alumina, pure air-slaked lime, steel turnings and gas-retort carbon were used. Using these in the proportions indicated by the equations, only a trace of alumina was obtained. Increasing the carbon to three times and the iron to twice theoretical, and melting the charge with the furnace over-powered to such an extent that dense fumes arose, the product was found to contain carbides of calcium, aluminum and silicon, sillimanite and quantities of a glassy substance. Analysis showed that 40 per cent of the silicon had been reduced and alloyed with the iron. About 30 per cent of the alumina was recovered. However, the prospects of successful commercial application are extremely poor, as under the most favorable test the cost of material alone would be more than $300 per ton. Moreover, there is no proof that calcium aluminate was formed, because with so much carbide present it is just as likely that the sodium aluminate obtained was formed by the decomposition of aluminum carbide and its subsequent solution in the sodium carbonate.

Technical News of the Week

Legislative Developments—Activities of Government Bureaus, Technical Societies and Trade Associations

Economics of Industry Discussed by Engineers

ociety of Industrial Engineers Holds Very Successful Convention in New York—Place of Engineer in Business Arouses Interest

OSEPH W. ROE was re-elected president of the Society of Industrial ngineers at the ninth annual conven- on held in New York, Oct. 18, 19 and). Professor Roe is a member of the xecutive board of the American Engi- eering Council and head of the de- artment of industrial engineering at ew York University. F. C. Schwedt- an, vice-president of the National City ank of New York, was re-elected easurer, and George C. Dent of Chi- go was continued as secretary and siness manager.

"Economics of Industry—the Funda- entals Necessary to Maintain Maxi- um Production with a Minimum Ef- rt, Waste and Cost" was the major bject of the convention, notable for e wide public interest attracted by the apers and addresses and for the co- eration of the United States Shipping oard, which made the event the occa- on for a declaration of policy as to e American Merchant Marine. The port of the American Engineering ouncil's committee on elimination of aste in industry shaped to a consider- le extent the proceedings of the con- ntion, at which the viewpoint of both orker and managing executive was esented.

On the opening day the delegates were ncheon guests of the Shipping Board oard the steamship President Hard- g at Hoboken. Commissioner E. C. lummer of the board made the journey om Washington to address the engi- ers. Mr. Plummer advocated the pas- ge of the bill providing aid for Ameri- n ships now before Congress as ecessary to economic development and e building up of American trade oad. "To delay is to play directly to the foreigners' hands," asserted r. Plummer.

President Roe, in his opening address, id that "the hard-boiled" factory man- er has been forced to accept the pure ientist from the laboratory and that e engineer, the chemist, the metallur- st, as the case may be, is now as cepted and necessary a part of large- ale industry as the accountant.

"We are at another joining of the ays," added Professor Roe. "Fifty ars ago it became apparent that in- strial waste and mechanical ineffi- ency were no longer negligible. To- y, with the increasing scale of pro- uction, it is becoming evident that cial wastes are no longer tolerable."

A major cause of overproduction, according to Professor Roe, is the ignoring of the law of diminishing returns by industrial leaders.

Engineers in Business

J. H. Pardee, president of the J. G. White Management Corporation, New York, discussing "The Part of Economics in the Formation of a Policy of Business Administration," said that the engineer has presented the broadest and most comprehensive points of view of business practices. Mr. Pardee said manufacturers should have a clearer understanding of the principal characteristics of their business.

Ernest Du Brul, general manager of the National Machine Tool Builders Association, Cincinnati, speaking on "The Economic Aspect of Production," said that the idea that mere fabrication creates value is a common error of industry, continuing:

"In this country we have had various destructive projects by big men in business, like the Ford and Edison and Durant schemes of currency and credit. We likewise have had some notable business smashups, to the tune of three-quarters of a billion of liabilities last year. Heaven only knows how much more was lost by those who did not smash but were able to survive the tidal wave of deflation. The biggest and most failures were among the manufacturers of various kinds, fabricators of goods. Do these failures not indicate that something is very wrong with the economics these men applied in management? Business gets into such a state because business managers start out on false premises due to incomplete knowledge of economic theory."

Welfare of Workers

Frank B. Gilbreth and L. M. Gilbreth of Montclair, N. J., presented a paper on "The Relation of Fatigue Elimination to Other Activities," which urged that the fatigue committee of the society work along two lines: First, increasing co-operation with others, engaged in other types of work; second, development of units, methods and devices that will be useful in the elimination of unnecessary fatigue.

A feature of the convention was a discussion by William Geiger of Newark, representing the workers, and John A. Faust of New York, representing the executives. Mr. Geiger answered the question of executives as to how production costs can be reduced by advising better use of the workers' time. Mr. Faust said that the remedy was to be found in the creation of a commission composed of high-grade specialists in financing, accounting and engineering. This commission, he said, would apply precautionary measures to business much as the Life Extension Institute applies them to the human body.

Robert B. Wolf, of New York, vice-president of the American Society of Mechanical Engineers and a member of the Hoover committee on waste in industry, in an address on "The Importance of the Elimination of Waste to the Economic Structure," said that in order to reduce industrial waste to a minimum industries must be so organized as to stimulate the workers' process of thinking.

Many Prominent Speakers

During the convention sessions were held by various groups, including managing executives, accountants and sales managers. Other speakers at the convention covered a wide range of activities. They included Dr. Lee Galloway, the Ronald Press; Prof. R. C. McCrea, Columbia University; Prof. Fred R. Fairchild, Yale; Prof. Edwin H. Schell, Massachusetts Institute of Technology; Prof. Edward J. Kunze, Pennsylvania State College; Miss Nellie Swartz, New York State Department of Labor; Dr. Louis I. Harris, New York City Department of Health; A. J. Lutterbach, Milwaukee; Charles Cheney, South Manchester, Conn.; O. L. Preble, New York; Dr. Davis R. Dewey, Massachusetts Institute of Technology; Francis H. Sisson, New York banker; Royal R. Keely, New York; Arthur J. Todd, Chicago; Earl B. Morgan, Philadelphia; Miss Louise B. Moore, Poughkeepsie, N. Y.

Activities of British Institute of Metals

A general program of the meetings of the British Institute of Metals and its local sections has been issued by the general secretary, listing a number of prospective papers of considerable importance. The Institute now has five local sections holding monthly meetings during the winter—namely, Sheffield, Scottish (meeting at Glasgow), Birmingham, London and North-East Coast (meeting at Newcastle-on-Tyne). The last has been organized during the summer. Walter Rosenhain, head of the metallurgy department of the National Physical Laboratory, has been chosen to deliver the annual May lecture.

Grasselli Medal Awarded to W. H. Fulweiler

American Section of Society of Chemical Industry Honors Gas Expert

The Grasselli medal, presented every year by the Grasselli Chemical Co. to the author of the best paper presented before the society during the previous year, was presented to W. H. Fulweiler, chemical engineer of the United Gas Improvement Co. of Philadelphia, at the regular meeting of the section at the Chemists' Club, New York, on Oct. 20. The presentation address was made by H. S. Miner, chief chemist of the Welsbach Co. of Gloucester, N. J.

Dr. Miner sketched the professional career of the medalist and described his numerous accomplishments in the field of applied research in the chemistry of the gas industry. Mr. Fulweiler is a graduate of the University of Pennsylvania and has devoted his entire professional career to the problems of the gas industry, having first served as superintendent of the Kansas City Gas Co., later in the department of tests of the United Gas Improvement Co., becoming chief chemist for that company and finally chemical engineer, the position which he now occupies. He was the first to apply the waste heat boiler in water-gas manufacture. The development of the well known road binder "Ugite" is the result of his research work, as is the "cut-back" method of tar production. During the war Mr. Fulweiler co-operated with the Ordnance Department in developing new processes for the manufacture of toluene. He is also responsible for the development of a new motor fuel for airplanes, which was a byproduct from the manufacture of toluene.

The medalist is well known as the author of many articles and papers on problems and developments of the gas industry.

In accepting the award, Mr. Fulweiler spoke briefly of the growth of the gas industry in this country, pointing out that in spite of the growing popularity of electricity for lighting, the production of gas has increased tremendously in the past 20 years. He expressed the belief that the adoption of the thermal standard starts a new era for the gas industry. He pointed out that the gas industry utilizes some of the most complicated physical and chemical reactions, although very little is known of the fundamental theory back of them. Consequently there is still a big field for research in the gas industry.

The enthusiastic reception which Mr. Fulweiler received was evidence that the choice of this year's medalist was a popular one.

Papers on Ozone

The subject for discussion before the meeting was ozone. Two papers were presented; the first, by F. E. Hartman of the United States Ozone Co., described ozone generators and their industrial application, while the second, by E. W. Felkel, of Mellon Institute, discussed the effect of ozone on organic compounds.

Mr. Hartman described the early attempts to manufacture on a commercial scale and traced the development of the modern ozone generator. He described the application of ozone to the drying of oils, giving the results of tests comparing the drying of varnish in air and in ozone. It has been established that the physical properties of the varnish are superior when the varnish is dried in ozone; the hardening period is reduced from weeks to hours and some special waterproof varnishes which cannot be satisfactorily dried in the ordinary way can be satisfactorily dried in an atmosphere of ozone. The speaker discussed the effect of ozone on varnish constituents. The action is, in general, both bleaching and oxidizing. Linseed oil is bleached by treatment with ozone. On the other hand, there are some oils that do not bleach on treatment, but after standing for a period of a week following the ozone treatment, they are decolorized. The explanation offered for this phenomenon was that the ozone forms ozonized air which later breaks down and gradually bleaches the oil. No oil has yet been found which cannot be bleached, either by simple treatment with ozone or by such treatment followed by a period during which this secondary action takes place.

Effect of Ozone on Organic Compounds

Mr. Felkel's paper described the general behavior of organic compounds when treated with ozone and particularly described the formation and properties of the ozonides. Ozone reacts on organic compounds in two ways: Ordinarily it is an active oxidizer, but with the unsaturated hydrocarbons, it forms addition products.

The formation and properties of the ozonides have been utilized in determining the structure of various organic compounds. For example, the constitution of oleic acid was discovered by first forming the ozonide and then breaking it up.

Industrial Applications

An interesting discussion of the industrial application of ozone was started by the inquiry of J. C. Olsen, who has worked with ozone in the treatment of contaminated water. Numerous applications were discussed, among which were the use of ozone in the air used for ventilating cold storage warehouses; for the purification of down and feathers and in smoke houses, to prevent the formation of mold on the meat.

Mr. Hartman stated that there are about 1,500 commercial installations of ozone water purification systems in this country. The most widespread application of the apparatus is in the treatment of water used for carbonated beverages. It has also been successfully used for purifying the water in swimming pools.

Technical Meetings to Feature Power Show

Engineering Societies Schedule Meetings to Coincide with Exposition in New York

The National Exposition of Power and Mechanical Engineering, to be held at the Grand Central Palace in New York from Thursday, Dec. 7 to Dec. 12 closing, however, on the intervening Sunday, is being planned in co-operation with the national societies interested in the economy of fuel and in the production and use of power generated therefrom.

The opening of the exposition in the Grand Central Palace will take place on the closing day of the annual meeting of the American Society of Mechanical Engineers, and time has been set aside in the A.S.M.E. program so that members may attend the opening exercises. Furthermore, the programs of the twenty sessions to be held at the A.S.M.E. meetings have been so arranged that all members attending the meetings may take in both the technical discussions and the exposition in the least possible time.

In addition, the A.S.M.E. professional divisions on aëronautics, ordnance and forest products will hold sessions of general interest to the engineering profession.

The American Society of Refrigerating Engineers is to hold its meeting at the Hotel Astor for three days commencing Dec. 5, and its members, as well as the members of the A.S.M.E., will be admitted to the exposition upon the presentation of their membership cards.

The opportunity this exposition offers for the power house operating man will also be grasped. The National Association of Stationary Engineers is perfecting plans for the various chapters to visit the exposition in a body. In addition, the New York Building Superintendents' Association, 600 strong, will attend in a body and they will be received by the officers of the N.A.S.E.

The great diversity of exhibits insures the particular appeal that this exposition will have to all engineers, as it will permit them to learn quickly and thoroughly of the progress in mechanical engineering. All industries using heat or power in any form will be interested in the displays of steam turbines, steam engines, steam boilers, feedwater heaters, superheaters, economizers, metering devices, stokers, coal handling apparatus, valves and pipe fittings. Each of the exhibitors is planning to emphasize the features of his product which denote progress.

Vitrefrax Company Plant Destroyed by Fire

The plant of the Vitrefrax Company at Los Angeles, Calif., was completely destroyed by fire on Sunday, Oct. 15. Reconstruction was begun at once along lines that will bring the capacity of the plant to a figure considerably higher than ever before.

Federal Coal Commission Begins Study

John Hays Hammond Appointed Chairman of President's Committee to Analyze Problems of Coal Industry

THE FIRST ACT of the United States Coal Commission at its initial meeting on Oct. 18 was to designate John Hays Hammond as its chairman. The commission immediately plunged into a discussion of a program for its exhaustive study of the problems of the coal industry. No formal announcement has been made as to how the work will proceed, but certain of its policies already are apparent. It is the intention of the commission to keep the public informed as to each step of its progress. It recognizes that in this way the public will be able to absorb more knowledge of the problems of the coal industry. The commission recognizes that the only chance that it has to accomplish anything is to obtain public support for its recommendations. It is believed that if the public mind goes through the same processes that the minds of the commissioners will go through, they will be prepared to pass intelligent judgment on the conclusions. Frequently when conclusions constitute the first knowledge that the public has, much time must elapse before their real purport is understood. Thinking takes time. Recognizing that fact, the commission hopes to be able to carry the public along with it as the study progresses.

Distinguished Personnel

The commission was appointed by the President on Oct. 10. Its personnel includes John Hays Hammond, well-known mining engineer; Thomas R. Marshall, Vice-President during the Wilson Administration; Samuel Alschuler, Judge of Seventh U. S. Circuit Court; Clark Howell, editor of the Atlanta *Constitution;* George Otis Smith, director of the U. S. Geological Survey; Edward T. Devini, teacher, writer and lecturer on social and economic questions and Charles P. Neill, expert on labor problems and conditions.

It is expected that the commission will appoint a fairly large staff of specialists who know how to collect coal information and put it together. It is believed the commission will hold as few formal hearings as possible and try to glean its information through more intimate contact with those who are acquainted with the industry. The hope is very generally expressed that the work will be divided among the individual members of the commission and among the commission's staff so as to amass data in that way rather than go through the time-consuming and generally unprofitable process of a public hearing.

The problem is so intricate that the commission expects to call to its aid each subdivision of the coal industry. One of its first acts was to invite into informal conference John L. Lewis, president of the United Mine Workers of America; Alfred M. Ogle, president of the National Coal Association, and S. D. Warriner, a leading anthracite operator, and to ask each to appoint a consulting committee, which is to maintain close contact with the commission and assist it by presenting such facts as may be called for from time to time.

Immediate Action Expected

Since E. E. Hunt is the secretary of the commission, it is reasonable to suppose that he will resort to much the same form of organization that functioned so successfully during the President's Unemployment Conference—the plan also used at the Conference on Limitation of Armament. At those conferences, advisory committees, composed of representatives of the varied interests concerned, were used with great success. For instance, an advisory committee on storage would be composed of representatives of coal operators and of large consumers—those most likely to benefit or be interested in storage. This plan, if acceptable to the present commission, would be carried out in a way so that an advisory committee would be formed for each of the important problems within the industry. In this way the commission would be saved a large amount of work and would be furnished with much predigested material.

Since the commission must make its preliminary report on Jan. 15, advantage must be taken of all means to expedite the study. It is probable that the commission will call upon those most concerned to loan it some of their specialists. Only in this way can the commission secure the requisite skill necessary to its work.

Daugherty Makes Capital of Chemical Foundation Suit

In a campaign speech at Canton, Ohio, on Oct. 21 Harry M. Daugherty, the Attorney-General, among other things said:

"We would have heard little criticism of the Department of Justice had it not been discovered that a case like the Chemical Foundation, for instance—in which valuable patents were assigned by public officials to companies which they themselves had organized—was under investigation, and the part played by those involved also was being scrutinized by government agents.

"And let me here, without giving any intimation as to who the men were, let me suggest that I have had the unique experience of sitting in the Department of Justice and listening to the story of a man formerly connected with the government and hearing patiently his pleas for certain fairly legitimate concessions, when, at the same time, in the city of New York, another former official, one of his associates, was busily engaged in getting contributions and making connections in order that the attacks upon the Department of Justice and the government might be increased, reinforced and successfully continued.

"I can give the names of these parties if ever they lift their voices to dispute this statement, but, unless I am authorized by them so to do, I should like to go through this entire investigation without prematurely mentioning names except in the orderly process of court proceedings. Their names, however, will be found in connection with certain litigation wherein some of the most important questions and some of the most questionable transactions and some of the most valuable properties in the world are in dispute, and the right and wrong of the transactions connected with the transfer of certain property must be determined in a court of justice."

Gas Analysis Basis for Automatic Control

Washington Chemical Society Has Demonstration of Novel Principle for Process Control

A most convincing demonstration of the manifold possibilities of automatic gas analysis for industrial process control was given by P. E. Palmer of the Bureau of Standards on Oct. 12 before the Chemical Society of Washington. Mr. Palmer illustrated a number of the automatic methods of analysis of gas mixture met commonly in industrial work and showed how the analytical apparatus could be made to control automatically the composition of these gases within narrow limits.

One of the most striking examples demonstrated was in the case of a mixture of sulphur dioxide, carbon dioxide, hydrogen and air. Three gas analysis cells were used in this apparatus, the first indicating or controlling the sulphur dioxide concentration, the second the carbon dioxide concentration, and the third the hydrogen concentration in the mixture. An automatic continuous record can be made of the percentages found.

The operation of the apparatus depends upon the difference in heat conductivity of the gas mixture and the same gas after removal of the constituent to be determined. Thus, in the case of sulphur dioxide the heat conductivity of a mixture containing it is compared with the heat conductivity of the same gas after passage through an iodine solution to remove the sulphur dioxide. In cases where it is not feasible to remove the constituent by any simple chemical method, the unknown gas may be compared with a known standard gas, and if pains be taken to maintain operating conditions properly, equally reliable results are obtained by this method.

The apparatus has been given successful test in a number of plants for long periods. Many interesting possibilities for further application have been suggested.

Dirigible Accident Hastens Helium Development

Destruction of C-2 Emphasizes Need for Improved Recovery Processes and Federal Action

As a result of the destruction of the dirigible C-2, the possibility is admitted at the War Department that no further use of hydrogen will be made in the inflation of ships of the dirigible type. There is enough helium available at present to inflate three ships of the C-2 type. The Fort Worth helium plant is again in operation, thus promising material additions to the present reserve. While the recovery of helium in that plant is costly, an effort is being made to increase the present reserve from 2,500,000 to 10,000,000 cu.ft. The gas from the Petrolia Field, which is comparatively rich in helium, is being burned, with the prospect that this unusually favorable source of supply soon will be gone.

Because of the great expense attached to the recovery of helium at present, it may be that practice with dirigibles will be discontinued until greater reserves are built up and cheaper methods of recovery devised. While the use of helium greatly reduces the fire hazard, it cannot be eliminated, since a gasoline load must be carried to operate the engines. Disaster can come in other forms to such craft, so it is doubtful if either the army or navy would be willing to risk any great amount of practice flying when an accident would mean the loss of one-third of the helium available.

Hope to Improve Process

Experiments conducted by the Bureau of Mines in its cryogenic laboratory have been so successful that a plant of semi-commercial size is to be built to demonstrate whether or not the laboratory method will work out on a larger scale. That plant will be in operation during the present fiscal year. Those who have followed these experiments are hopeful that a great reduction in the cost of recovery will be found possible.

Before any extensive use of dirigibles inflated with helium is attempted, it is probable that the ships will be redesigned. This can be done so as to result in considerable efficiencies. It will be possible to place the engines very close to the envelope, thereby greatly increasing their efficiency and making possible greater ease in the manipulation of the craft. There is every reason to believe that the fire hazard can be reduced until it is no greater than in the case of airplanes.

Accident Will Hasten Action

The accident to the C-2 is certain to stimulate the consideration of the helium bill now before Congress. Hearings on this measure are to begin in November or December. This bill has received the approval of the President and of several members of the Cabinet. It proposes to centralize in the Bureau of Mines all matters pertaining to the conservation and production of helium. The army and navy is to be given first call on any supplies developed. The bill provides a revolving fund of $5,000,000, of which a part can be used for the construction of a plant, the purchase of leases and in the conservation of existing supplies. The remainder is to be used as an operating fund. The helium produced is to be turned over to the army and the navy, which are to reimburse the revolving fund. Any surplus not needed for military purposes can be sold or leased for commercial use. The bill also prohibits the export of any helium.

The President is on record as favoring this legislation. Before the bill was sent to Congress, the Secretary of the Interior took the matter up with the President. In that connection the President wrote Secretary Fall:

> I have received a copy of the proposed bill authorizing the conservation, production and exploitation of helium gas, which you recently sent me.
>
> I note that the Secretary of War and the Secretary of the Navy, as well as yourself, strongly approve this bill. I agree with you that the matter in question is of great importance and that Congress should make provision for obtaining a proper supply of helium for the future needs of the army and navy. Conditions for extracting the gas at a reasonable cost should also be made as favorable as possible. Since this country has practically a monopoly of helium resources at the present time, it would appear to be advisable to hold this monopoly and exercise control over exportation of the gas. I believe that the bill in question covers these points and I therefore suggest that you transmit it to the Military Committee of the House and of the Senate with a recommendation for its early consideration.

Helium occurs in the gas of a number of American fields. It is estimated that enough of it is going to waste each day to fill a dirigible the size of the ZR-2. An indication that the recovery of helium at a cost which is not prohibitive is not regarded as improbable is the fact that rights to construct zeppelins in this country have been obtained and construction is now in progress. These interests are considering the production and use of helium.

Committee to Investigate Direct Oxidation Method of Sewage Disposal

Following the reading of a paper before the American Public Health Association in Cleveland, Oct. 19, by G. W. Fuller on "Sewage Disposal at Lima, Ohio," discussion centered on the so-called "direct oxidation process." This is the method formerly known as the Landreth electrolytic lime method which had previously received attention of engineers and sanitarians following investigations and experiments at Elmhurst, N. Y.; Decatur, Ill.; Phillipsburg, N. J., and Allentown, Pa.

The Sanitary Engineering Section of the A.P.H.A. decided to appoint a committee to investigate the efficacy of this process and to make its report at the next annual meeting of the association. In addition to members of the Sanitary Engineering Section, this committee is to include a representative of the American Electrochemical Society.

German Reparation Dyestuff Deliveries

Bulk of Them Made Right After the Armistice—Italy Has Received the Most

Contrary to the popular conception that Germany reparation deliveries of dyestuffs have been made in large proportion since the London schedule of payments, a study of the records by the Western European Division of the Department of Commerce shows that the major deliveries were made during the months following the armistice, in the first efforts of Germany to meet the requirements of the Versailles treaty. The London schedule of payments became effective on May 1, 1921.

Distribution of the deliveries made previous to May 1, 1921, was as follows:

	Gold Marks
France	9,251,000
Italy	9,124,000
British Empire	8,499,000
Belgium	2,949,000
Japan	2,630,000
Serb-Croate-Slovene State	23,000
	32,476,000

On May 1, 1921, Germany began deliveries on account of the annuities described in the schedule of payments and dyestuff deliveries are now credited to annunity payments only. From that date to June 30, 1922, they totaled 10,708,000 gold marks distributed as follows:

	Gold Marks
Italy	5,589,000
Belgium	3,221,000
France	2,006,000
British Empire	1,696,000
Greece	196,000
	10,708,000

Thus during the 31 months previous to the London schedule the deliveries were 75.2 per cent of her total deliveries, leaving 24.8 per cent during the 14 months since that schedule became effective.

An interesting fact which appears in the records of deliveries is that the largest deliveries have been to Italy, rather than to France and Belgium, as popularly believed. Deliveries to France were one million gold marks less than to Italy, while those to Belgium were less than half as great as to Italy. The total distribution to June 30, 1922, was as follows:

	Gold Marks	Percentage
Italy	12,213,000	29.4
France	11,257,000	26.0
British Empire	10,195,000	23.6
Belgium	6,170,000	14.3
Japan	2,630,000	6.1
Greece	196,000	.5
Serb-Croate-Slovene State	23,000	.1
	43.184.000	100.0

The above tables include only the deliveries distributed among the powers. In addition to these, from the beginning of German deliveries to June 30, 1922, dyestuffs to the value of 4,000,000 gold marks were sold through the Reparation Commission to the Textile Alliance of the United States and others to the value of 3,000,000 gold marks were resold to German buyers. These sums were credited as cash received rather than as deliveries in kind.

Engineers Discuss Scientific Management

Many Joint Meetings of Three Societies Feature "Management Week" in Various Cities

Management Week meetings, bringing forcibly to public attention the increasing importance of the engineer in industry, were held in thirty cities, Oct. 16 to 21, under the auspices of the American Society of Mechanical Engineers, the Society of Industrial Engineers and the Taylor Society. With these societies, other engineering organizations and civic and economic bodies co-operated.

President Dexter S. Kimball and Vice-President L. P. Alford were among the principal speakers. Dean Kimball addressed the Central Pennsylvania local section on Oct. 16, the Cincinnati section on Oct. 19, and the Columbus section on Oct. 20. Mr. Alford spoke at Meriden, Conn., on Oct. 6; at New York on Oct. 17, and at Plainfield, N. J., on Oct. 18. A meeting at St. Louis on Oct. 11 was addressed by John Lyle Harrington of Kansas City, president-elect of the A.S.M.E.

Mr. Alford's paper, entitled "Ten Years Progress in Management," was read at meetings in several cities, including Birmingham, Ala., Davenport, Ia., and Chicago. Mr. Alford elaborately reviewed the history of the advance of scientific management. "Industry and business as developed in modern civilization must continue, else infinite misery will overtake the human race," said Mr. Alford. "Management is the agency by which community, state and nation shall endure."

Engineers in Management

Messages presenting the American, the English and the German points of view were read at meetings throughout the country. Dean Kimball, speaking for the American engineer on the question of management, said:

"The engineer has been drawn into the field of management partly because of his proximity to the problems of industry, partly because of the exigencies caused by the rapid growth of scientific methods, but more particularly because of his scientific method of attacking problems of all kinds. It has been found that his methods of attacking the problems of design and construction are powerful tools in handling the problems of administration. There can be little doubt that the engineering executive is to remain a dominant figure in industrial management. I do not contend that he alone can solve these human problems, but I do believe that if he will give his best effort to this work he can make a contribution that will go a long way toward the attainment of industrial peace."

Messages From Abroad

James F. Whiteford, discussing "Development of Management in the United Kingdom," said: "In general, it may be stated that management practices in the United Kingdom are following very closely the same sequence of developments as have been instituted in American industries. The application over there is a few years late, but the best portion of the practices in American industries is being fairly generally accepted over there."

G. Schlesinger of Charlottenburg, Germany, told of "The Development of Scientific Industrial Organization in Germany," saying: "It gives me pleasure to be able to place before the American industrial world some proofs of successful results in scientific and practical industrial organization in Germany. I am convinced that after a long period of 'lagging behind' we have at least caught up with the Americans in scientific management; but the deeper foundation that we possess and the greater economy in the manipulation of our system (we can carry out the work of accounting in factories according to our method with half the personnel that is required with the usual American system) will perhaps prompt American industry to take note of our organization science and practice, as the German industry once gladly and gratefully accepted advice and information from American sources."

New York Meetings

Conspicuous among the Management Week meetings were those held in New York, Chicago, Indianapolis and Cambridge, Mass. Fred J. Miller presided at the New York meeting, speaking generally on the results attained by scientific management and on its potentialities. Other New York speakers were Myron H. Clark, of the United States Rubber Co., John H. Williams of Philadelphia and Frank B. Gilbreth of Montclair, N. J.

Meetings in Various Cities

Three meetings were held in Chicago at the Auditorium Hotel, the keynote being "true wealth and prosperity come only from careful, unwasteful management of productive enterprises, coupled with industry and thrift." The Boston Engineering Societies participated in the Cambridge meeting held at Harvard University. Other co-operating organizations were Boston Chamber of Commerce, Associated Industries of Massachusetts, Taylor Society, Society of Industrial Engineers, Boston Association of Stock Exchange Firms, Massachusetts Bankers Association and Harvard Graduate School of Business Administration.

Management mechanisms and their efficiency is one vital subject which the industrial engineer studies. Stores control, standardization of operation, cost accounting, educating the employee, scheduling and planning are all management mechanisms. Human engineering is an elaborate title for the vital work being done on employee-employer relations and throughout all their work must be the leaven of service and an emphasis on the service motive—a real industrial co-operation which is the only basis for ultimate industrial health.

Potash Producers Must Work Own Salvation

"Desperate but Not Hopeless," Says Association Secretary

The domestic potash industry has been dealt a severe blow by failure to protect it from foreign competition in the new tariff act, but by careful management and reductions in costs it will survive and eventually develop health, in the opinion of Frederick W. Brown, secretary of the United States Potash Producers Association.

Reports show that the Nebraska field is completely out of production. The Nebraska output, while low in salt content, formerly supplied approximately half of the United States tonnage. The only activity in Nebraska at present is by one company which is sinking a well in hope of striking either oil or gas which would give cheap fuel and permit operation.

There are only three companies in general commercial operation for potash now, in contrast to the high record of 77, exclusive of wood-ash producers, in 1918, this figure declining to 18 in 1921. These three are the American Trona Corporation of Searles Lake, Calif., with potash deposits, and two byproduct plants, that of the Santa Cruz Portland Cement Co. of San Francisco, which produces from cement mill dust, and the United States Industrial Chemical Co. of Baltimore, producing from alcohol distillery waste. There are two, possible three, other cement plants which are selling dust locally, to farmers who bring their wagons to the plants.

While production is far below the war records, the potash now being produced is of very much higher grade on the average than the war-time average. Despite conditions in the domestic industry, potash men are pushing ahead to develop their business in hopes of eventually being able to meet the German and French competition, probably by a combination of an increase in the price of the foreign product and a lowering of their own costs.

The core drill being sunk in west Texas to determine the stratum of the potash deposits known to exist over a wide section of that country is reported to be down about 900 ft. This potash is known to be comparable to the best German potash.

Mr. Brown expects a combination of the French and German potash interests and a considerable increase in their prices this year. The condition of the domestic industry is summed up by Mr. Brown in the phrase, "desperate, but not hopeless."

Feldspar Producers Contemplate Organization

Feldspar producers throughout the country have been invited to gather in Washington on October 25, to determine whether or not to form a national association. The meeting will be held in the director's office of the Bureau of Mines, at 11 o'clock a.m.

Personal

CHARLES T. BRAGG, formerly with the Michigan Smelting & Refining Co., is now president and general manager of the Michigan Valve & Foundry Co.

Dr. FRANK K. CAMERON, general manager of the Salt Lake Insecticide Co., Salt Lake City, Utah, gave an interesting address at a recent meeting of the mining committee of the local Commercial Club, dealing with the conversion of the scorodite ores of the Western Utah Copper Co. into calcium arsenate.

FRED W. COHEN, assistant general manager of the Metal & Thermit Corporation, has gone to Europe for an extended business trip.

J. V. N. DORR returned a few weeks ago from a 6 months' trip to England, France and Germany, where he inspected numerous installations of his machinery in the metallurgical and chemical plants of those countries.

FRANK HODSON, president of the Electric Furnace Construction Co., has just returned from a trip to Europe, having been gone several weeks.

E. J. JANITZKY has been awarded the gold medal for the best paper presented before the annual meeting of the American Society for Steel Treating, held a year ago at Indianapolis. His paper "Influence of Mass in Heat Treatment" was reprinted in *Chemical & Metallurgical Engineering*, vol. 25, page 783. The second prize was awarded to Messrs. Gill and Bowman for a paper on the "Constitution of High-Speed Tool Steel."

H. A. LINCH, director of the Westport Mill, has begun an inspection of the beet sugar industry both in this country and abroad.

W. E. MCCORMICK has been appointed development engineer at the tire and tube departments of the Youngstown, Ohio, plant of the Republic Rubber Corporation. E. A. Armstrong has been made general superintendent at the plant.

WALTER S. MCKEE has resigned as vice-president and director of the American Manganese Steel Co. and will develop the business of the Inland Engineering Co. of Chicago, of which he is president.

Dr. GEORGE OTIS SMITH has been appointed a member of the President's Coal Commission, which will make it necessary for him to reduce his duties as director of the U. S. Geological Survey. P. S. SMITH will act as director during the time that the Coal Commission will require the major portion of Dr. Smith's time.

F. B. TOUGH, United States supervisor of oil and gas operations on leased public lands, has been appointed chief petroleum technologist of the Bureau of Mines, to succeed A. W. Ambrose.

The president of the American Electrochemical Society has appointed an advisory committee to co-operate with the Bureau of Mines in its electrometallurgical work. The committee is constituted as follows: Carl G. Schluederberg, Westinghouse Electric & Manufacturing Co.; Acheson Smith, Acheson Graphite Co.; Frank W. Brooke, Electric Furnace Construction Co.; Daniel L. Crosby, Detroit Electric Furnace Co.; C. B. Gibson, Westinghouse Electric & Manufacturing Co.; John A. Seede, General Electric Co.; Robert Turnbull, U. S. Ferro Alloys Co.; F. A. J. FitzGerald, consulting metallurgist, Niagara Falls.

The American Mining Congress elected the following officers at the twenty-fifth annual convention of the organization recently held in Cleveland: President: Sidney J. Jennings, vice-president, U. S. Smelting & Refining Co., New York City. Directors: Daniel B. Wentz (re-elected), Philadelphia, Wentz Coal Corporation; William Lindsay, Napier Iron Works, Nashville, Tenn.; W. C. Doering, Southern Wheel Co., St. Louis; Albert Nason, Nason Coal Co., Chicago, Illinois. Vice-presidents: Daniel B. Wentz; H. W. Seaman, Chicago; E. L. Doheny, Mexican Petroleum Co., New York.

Obituary

FRANK SHERMAN WASHBURN, chairman of the board of directors of the American Cyanamid Co., whose death on Oct. 9 was briefly noted in these columns last week, was a pioneer in the development of the process of extracting nitrogen from the air. He was born in Centralia, Ill., Dec. 8, 1860, the son of Elmer Washburn, a former president of the National Livestock Bank of Chicago. He was graduated as a civil engineer from Cornell in 1883 and became associated with railroad engineering in the Middle West. He reorganized the belt line of the Union Stock Yard & Transit Co. and then was sent abroad by the Chicago & Northwestern, Illinois Central and several other railroad companies to study railway economics in Europe.

FRANK SHERMAN WASHBURN

Upon his return from Europe in 1889, Mr. Washburn played an important part in the development of Purdy's dam and reservoir and other sources of New York City's water supply. Later he went to Chile as consulting engineer in connection with the production and shipment of Chile's nitrate of soda. His next important work was as consulting engineer in connection with the building of an interoceanic canal in Central America, a project which was abandoned when the United States Government undertook the building of the Panama Canal.

After some years spent in developing coal and iron mining and water-power projects in the South, Mr. Washburn saw the possibilities of application of hydro-electric power to the fixation of air nitrogen for the manufacture of fertilizers. The result was the organization of the American Cyanamid Co. Factories were erected at Niagara Falls on the Canadian side, which since have developed an annual production of cyanamid for fertilizer and chemical use valued at more than $10,000,000.

Before the war, Mr. Washburn foresaw that if the Chilean supply of nitrate of soda upon which the United States depended for making military explosives were cut off, this country would be seriously menaced. As early as 1910 he gave his thought to a means of making America independent of South American deposits so that in the event of an enemy blockade the country could produce its own nitric acid. The German Government had already started on a large scale, for military purposes, the same fixation of air nitrogen which Mr. Washburn and his associates had applied to agriculture.

So with the entrance of America into the World War, Mr. Washburn and the American Cyanamid Co. were requested by the Ordnance Department to organize the Air Nitrates Corporation to construct and operate for the government the huge $50,000,000 air nitrates plant at Muscle Shoals, Ala. Mr. Washburn was the president of the corporation. Although the armistice came before the Muscle Shoals plant and two others near Cincinnati and Toledo were completed, this great war project is one of the few that could be turned to peace time use.

Mr. Washburn was president of the Goodman Manufacturing Co. of Chicago. He was married in 1890 to Miss Irene Russell of Augusta, Ga., a member of an old and prominent Southern family. He was a trustee of Cornell University for two terms and also of Vanderbilt University. He was a member of the American Society of Civil Engineers, American Institute of Mining Engineers, Society of Western Engineers, American Institute of Electrical Engineers, American Electrochemical Society, Alpha Delta Phi and Sigma Xi, the honorary scientific society. Among his clubs were the University, the Apawamis and the Century.

Market Conditions

In Chemical, Metallurgical and Allied Industries

A Survey of the Economic and Commercial Factors That Influence Trade in Chemicals and Related Commodities
Prevailing Prices and Market Letters From Principal Industrial Centers

A Persistent Shortage of Unskilled Labor

A Great Decrease in Immigration Is Partly Responsible for This Shortage—How Extensive Will It Become? Will It Effect a Change in the Manufacturer's Attitude Toward Labor?

UNSKILLED LABOR is an essential to chemical industries. In fact, the proportion of skilled labor, in the ordinary sense of the word, to unskilled labor in chemical plants is exceedingly small. Unlike the mechanical industries, the proportion which labor cost represents of the total cost of a product is small. All generalizations on this subject are somewhat unsafe, but 15 per cent might be said to represent as close an estimate as possible. Labor problems in chemical industries, since they represent only 15 per cent of the total cost, and since this labor is largely unskilled, have never held a predominant position in the minds of chemical executives. Nevertheless the labor shortage during war time brought home to chemical companies the necessity of having a supply of such labor as is needed and brought it home hard. There followed the period of prosperity in 1920 during which time the returning soldiers and workers in war-time industries eliminated the labor problem. In 1921 manufacturers began to forget that there ever was a labor problem, for there was always a large supply of workmen waiting at the factory gates for an opportunity to work. And then when they had completely forgotten the problem it loomed up again, especially in industries analogous to the chemical industries wherein unskilled labor is in demand. The first important notice which was taken of this shortage was when the U. S. Steel Corporation advanced common labor wage 20 per cent, and now it is a common cry that unskilled labor is not to be had.

A search into the reasons for this shortage is worth while in order to determine the probable extent of the shortage and whether any remedies suggest themselves. Service letter No. 123 of the National Industrial Conference Board of July 3, 1922, discussed the labor shortage at some length, mentioning the many localities which had already felt the shortage and the time when the shortage began to appear; then it went on to point out that under the present immigration act only one-tenth the net increase in population due to immigration was recorded in 1921 as against the pre-war rate. In the year ended June 30, 1922, 309,556 men, women and children were admitted to this country, whereas 198,712 left the country. This is a net gain of 110,000 persons, yet when we come to study the classifications of these people we find only 32,724 laborers among the immigrants and over 100,000 emigrating. This amounts to a net loss of 67,334 laborers, and it is on this class of labor that chemical industries must depend, a significant loss that demands immediate executive attention.

So we are faced with a shortage which is likely to increase rather than decrease unless a radical change in the national policy toward immigration takes place. The immediate effect of this situation will be a scurry by manufacturers to enlist the aid of nostrums and formulas designed to "solve" all labor troubles. For example, many firms will take out life insurance for the benefit of its employees and profit-sharings schemes will come into being by the gross. All of this will be a frantic gesture on the part of managements to retain their common labor. It will largely be unsuccessful, for the laborer can sense with uncanny accuracy the spirit which moves management and will recognize such gestures as the above in their true light—a primarily selfish motive. The answer will have to be a complete change of attitude. From neglect of labor problems and temporary palliative, management will have to adopt constructive measures, an attitude which begins with a sound philosophy of labor's share in manufacturing enterprises and which is synthesized with a true sense of justice toward labor. There are enough successes as a result of this attitude to warrant adherence to it. "A word to the wise is sufficient!"

When an Irresistible Force Meets an Immovable Body

The irresistible force in this specific instance of the proverb is American productive capacity and energy. The immovable body is economic law. For a long time we have been a debtor nation and our trade balance, the ratio of exports to imports, has been favorable—that is, greater than 1. Now we are a creditor nation, and economic law states that our balance of trade must become unfavorable—that is, that imports must be greater than exports. Does this mean that our productive capacity, if it does not actually fall off, will at least not keep pace with its expected increase and with the increase which would normally be expected from the survey of the past half century? This increase up to the present time has been the most amazing industrial development ever recorded and it actually takes on the proportions of an irresistible force.

Before we enter cyclone cellars to await the crash, we might consider the words which Secretary Hoover advanced in his Toledo speech on this subject. Certain unique factors enter into any settlement of international balances between Europe and America, such as the annual expenditure of American tourists abroad, the remittances of immigrants in the United States to their relatives abroad, the growing volume of investments made by Americans in foreign countries, interest upon investments in the United States of private citizens of debtor countries and such other items as are usually called invisible exchange. This invisible exchange was estimated to be one and a half million dollars in the last fiscal year, a year of depression. It is likely to increase, so it is perhaps possible that American productive capacity may still maintain a favorable balance of trade, even though we are a creditor nation. There is at least food for thought. There usually is in anything Herbert Hoover has to say.

"Chem. & Met." Weighted Index of Chemical Prices

Base = 100 for 1913-14

This week	157.71
Last week	153.77
October, 1921	151
October, 1920	263
April, 1918 (high)	286
April, 1921 (low)	140

Only one of the commodities declined in price during the last week, ammonium sulphate, and that very slightly. The relatively large increase in the index number is due to increases in the prices of commercial solvents, particularly methanol, and also of linseed oil, both of which are important factors in the index calculation.

Price Fluctuations and the "Reasons" for Them

Every now and then it is desirable to dip behind the scenes and evaluate the reasons given for the rise and decline of the market price of commodities. A commodity is advanced in price. Consumers as well as economists and students of markets ask: Why? Frequently the answer is "increased cost of production," and occasionally this answer may be correct. On the other hand, it must be remembered that unless the market is strong and the demand vigorous, an increased cost of production would not, could not, affect the selling price. Let us take, for example, the increased price quoted on commercial solvents during the past week. It so happens that the shortage of common labor, already referred to, has very definitely increased the cost of manufacturing these products. Lumbering was one of the first industries affected by the labor shortage. On the other hand, this effect has been felt in the industry for some months and yet from February until the end of September there was no change in quoted prices and some contracts most advantageous to the consumer were made at prices well under market quotations. In September the demand began to stiffen, perhaps because excess stocks had been used up, and within a month the price increase has been 25 cents per gallon. In other words, the increase in selling price lagged behind the increase in manufacturing cost probably by months.

Chemical Market Is Speculative

Thus to give as a reason for the increase in selling price the increased cost of production is not a fair statement of the case. In other words, the formal reasons given for price increase must be discounted. The real reasons or the immediate reasons for most price changes can be traced to the speculative nature of the market. This situation is inevitable when a commodity market is handled through brokers, dealers and selling agents. Their big profits (and big losses too) are derived from fluctuating markets, and the tendency is therefore to develop a speculative market. The effect of this upon manufacturers depends upon the proportion of their business which is handled in this way. Large fluctuations in price are apt to be very dangerous to producers, although it must not be supposed that some of them do not welcome a fluctuating market.

The Middleman's Wings and Halo

This must not be construed to be an indictment of the middleman. It happens to be the Mr. Hyde side of him and it is on the whole an unbalancing and therefore detrimental influence to the industry. There are plenty of reasons why the middleman is a Dr. Jekyll to this industry as well as all industries. He needs no defense. If he were nothing more than a sensitive barameter, he would fill a valuable function.

The St. Louis Market

St. Louis, Oct. 19, 1922.

The market for industrial chemicals has now settled down considerably after a very exciting period brought about by the new tariff. However, inquiries are still very heavy and actual buying is being continued in large volume. Nearly all orders received are for immediate shipment, as buyers are encountering more difficulties each day with transportation facilities, and furthermore, many large consumers wish to cover their winter requirements of certain commodities at this time of the year. There have been no important price changes since our last report, and apparently domestic producers have about adjusted their prices to meet the foreign competition. In view of the transportation difficulties and the shortage of stocks created by the sudden demand of several weeks ago, buyers should anticipate their requirements very liberally until the freight movement becomes easier and production again normal.

Alkalis

Only routine business is being transacted in the alkali market at present and prices remain as they have been for the past 60 days. Not much of a change either way is expected, for some time to come. *Caustic soda solid* is being quoted in 5-drum lots at $3.85 per 100 lb. delivered buyer's door, with a 55c. differential for the flake. Plenty of stock on consignment in this market. *Soda ash*, 58 per cent light, is quoted at $2.20 in bags and $2.40 in barrels for 5 to 10 barrels or bags. *Bicarbonate of soda* is being passed along at $2.40 per 100 lb. generally, although in a few cases this has been shaded to $2.25. *Sal soda* can be had generally at the buyer's price, barrels having gone as low as $1.65 per 100 lb., with kegs at $1.90.

General and Special Chemicals

The heavy mineral acids are moving in large volume and the demand is increasing. Prices are quite firm and stocks very limited. *Acid carbolic crystals* is moving very freely and in large volume at the present prices. While the demand for *citric acid* is only routine, the tight situation which has existed for some time is still in evidence and spot stocks are extremely light. Domestic producers are still unable to bring up their production to meet the demand from the regular trade. Prices are very firm. There is no heavy demand for *tartaric acid* at this moment, but sales of large volume are being made through regular channels. The demand for *phosphoric acid sirupy* is nil. *Aqua ammonia, 26 deg.*, has firmed up a bit, but the demand is only routine. The *white arsenic* market has advanced very sharply since our last report and is now being quoted at 9½@10c. New York, with practically no stocks available. Some domestic producers are sold up entirely and their output is insufficient to take care of their regular trade. *Carbon bisulphide* has slowed up a bit and spot goods are easily obtainable. The *copperas* situation is still unchanged, the demand greatly exceeding the supply. Prices are quoted at $20@$21 per ton in bulk f.o.b. producers' works. *Glycerine* is holding firm at 18½c. in drums and a further rise in price might make its appearance in the near future. *Sulphur* is still being quoted at the very low figure of $1.90 per 100 lb. for the commercial flowers, and we judge that the fight between the producers is still on, since this is abnormally low for sulphur. *Zinc dust* has advanced sharply and is now being quoted at 10c. in carload lots f.o.b. New York. In our last report we intimated that an advance in *zinc sulphate* should be expected at any time, and today carload lots are being quoted at 3½c. f.o.b. St. Louis; less than carload lots at 3¾c. f.o.b. St. Louis, showing an increase of ¼c. A still further advance may be expected at any time. Stocks in the hands of producers are only fair.

Vegetable Oils and Naval Stores

Turpentine is climbing steadily upward and it seems that the end is not yet. Today's market quotes turps in 5-bbl. lots at $1.60 and single barrels at $1.66 per gal., which is a jump of 10c. per gal. over yesterday. *Castor oil* is firm at 14c. in drums, with no indication of a price decline. Sales are better than normal. *Linseed oil* is moving in good volume and quite a bit of contract business, in some cases coming to May 1, is being done. Spot prices in 5-bbl. lots are 90c. for raw; 92c. for boiled, while single barrels are held at $1 for raw; $1.02 for boiled.

The New York Market

New York, Oct. 23, 1922.

Domestic inquiry has shown material improvement during the past week, especially for the more important basic commodities. Importers, however, were eager to dispose of some surplus stocks of lesser items and slight shading of quotations resulted. The demand for bleaching powder, caustic soda and soda ash was maintained and considerable business was transacted for home consumption. The most noteworthy feature of the week's activities was the acute advance in all solvents. Manufacturers announced advances in acetone, acetate of lime, formaldehyde and methanol, due to increased costs of production. Formaldehyde showed the most strength, with spot supplies very limited and demand strong. Commercial white arsenic retained its past strength and distributors were again inclined to raise prices. Prussiate of soda, barium carbonate and chloride, permanganate of potash and sal ammoniac showed slight reductions, due to a desire on the part of several smaller importers to dispose of surplus stocks. Citric and tartaric acids were in good demand and a fair volume of business was transacted. Acetic and sulphuric acids were quite firm, with the former quoted at slightly higher
